ON THE QUANTITATIVE SOLUTION STABILITY OF PARAMETERIZED SET-VALUED INCLUSIONS

A. UDERZO

Abstract. The subject of the present paper are stability properties of the solution set to set-valued inclusions. The latter are problems emerging in robust optimization and mathematical economics, which can not be casted in traditional generalized equations. The analysis here reported focuses on several quantitative forms of semicontinuity for set-valued mappings, widely investigated in variational analysis, which include, among others, calmness. Sufficient conditions for the occurrence of these properties in the case of the solution mapping to a parameterized set-valued inclusion are established. Consequences on the calmness of the optimal value function, in the context of parametric optimization, are explored. Some specific tools for the analysis of the sufficient conditions, in the case of set-valued inclusion with concave data, are provided in a Banach space setting.

1. Introduction

Let $F : P \times X \rightrightarrows Y$ be a given set-valued mapping and let $C \subset Y$ be a (nonempty) closed and proper subset of $Y$, where $P$, $X$ and $Y$ are metric spaces. Fixed any $p \in P$, the problem:

$$\text{(SVI}_p) \quad \text{find } x \in X \text{ such that } F(p,x) \subseteq C$$

is called parameterized set-valued inclusion. As $P$ plays the role of parameter space, $(\text{SVI}_p)$ is the parameterized form of a class of problems, which recently emerged in optimization and variational analysis. More precisely, they arise in the context of robust and vector optimization, in mathematical economics (see [22, 23]), while it seems to be reasonable that they may be of interest also in set-valued optimization, where partial orders over sets are formalized in terms of set inclusions. Such kind of problems can not be casted in traditional generalized equations. In the terminology of set-valued analysis, the former ones correspond to determining the upper inverse image of a set through a multifunction, in contrast to the latter ones, which are somehow related to the lower inverse image.

To the best of the author’s knowledge, set-valued inclusion problems were firstly studied in [4], where an error bound is obtained by tools of convex analysis. Subsequently, several topics related to their solution set have started being systematically investigated in some more recent works: solution existence and error bounds via a different approach have been established in [22]; primal and dual elements for the tangential approximation of the solution set have been provided in [23]. Following this line of research, the present paper aims at beginning a perturbation analysis for the problem at the issue, by considering a parameter dependence as in $(\text{SVI}_p)$. Such a perspective leads to undertake a study of the stability properties of the solution set. A way to do this “quantitatively” consists in investigating Lipschitz semicontinuity properties of the solution mapping associated with the parameterized class of set-valued inclusions, i.e. the (generally multi-valued, with possibly empty values) mapping $S : P \rightrightarrows X$, defined by

$$S(p) = \{ x \in X : F(p, x) \subseteq C \}.$$

These well-known properties found manifold relevant employments in variational analysis as generalization of the notion of Lipschitz continuity. In the present analysis, they turn out to afford fruitful insights on the behaviour of $S$, such as nonemptiness, linear dependence on the parameter
perturbations near a reference value \( \bar{p} \in P \) of the distance of its values from an element \( \bar{x} \in S(\bar{p}) \), or from the whole set \( S(\bar{p}) \). A key aspect of the issue is that all these features are measured by a suitable modulus associated with each of the Lipschitz semicontinuity properties.

The contents of the paper are arranged in the subsequent sections according to the following synopsis. In Section 2 several Lipschitz semicontinuity properties for set-valued mappings acting between metric spaces, along with their moduli, are presented, connections with other continuity and Lipschitzian type properties of large employment in variational analysis are discussed, and the basic tools of analysis are laid down. In Section 3 a sufficient condition for each of the Lipschitz semicontinuity properties presented in the previous section is established in terms of differential conditions valid in a metric space setting. Each of them is complemented with a quantitative estimate of the respective modulus. Section 4 explores some consequence of the aforementioned findings on the optimal value analysis in the context of parametric optimization, for problems whose feasible region is defined by a set-valued inclusion. In Section 5 the analysis of the differential conditions introduced in Section 3 is deepened in a Banach space setting. More precisely, under a concavity assumption on the set-valued term defining an inclusion problem (SVI\( \Sigma \)), the fulfilment of the above conditions is shown to be guaranteed, and somehow measured, by the occurrence of the metric \( C \)-increase property.

The notation in use in the paper is standard. If \( A \) is a subset of a metric space \((X,d)\), and \( x \in X \), dist \((x,A) = \inf_{a \in A} d(x,a)\) denotes the distance of \( x \) from \( A \). The closed ball centered at \( x \) with radius \( r \geq 0 \) is indicated with \( B(x,r) \), whereas \( B(A,r) = \{ x \in X : \text{dist}(x,A) \leq r \} \) denotes the \( r \)-enlargement of the set \( A \subseteq X \). Given a function \( \psi : X \to \mathbb{R} \cup \{ \pm \infty \} \), by \( [\psi \leq 0] = \psi^{-1}((-\infty,0]) \) the 0-sublevel set of \( \psi \) is denoted, whereas \( [\psi > 0] = \psi^{-1}((0,\infty)) \) stands for the 0-superlevel set of \( \psi \). Given a set-valued mapping \( \Phi : X \rightrightarrows Y \), \( \text{dom} \Phi = \{ x \in X : \Phi(x) \neq \emptyset \} \) indicates the domain of \( \Phi \), while, given \( C \subseteq Y \), \( \Phi^{-1}(C) \) indicates the upper inverse (image) of \( C \) through \( \Phi \). The acronyms l.s.c. and u.s.c. stand for lower semicontinuous and upper semicontinuous, respectively.

2. Lipschitz semicontinuity and calmness properties

Before any discussion, it is proper to recall the quantitative semicontinuity properties that will be considered in the present work.

**Definition 2.1** (Lipschitz semicontinuities). Let \( \Phi : X \rightrightarrows Y \) be a set-valued mapping between metric spaces. \( \Phi \) is said to be:

1. **Lipschitz lower semicontinuous** at \((\bar{x},\bar{y}) \in \text{graph} \Phi\) if there exist positive constants \( \delta \) and \( \ell \) such that

\[
\Phi(x) \cap B(\bar{y},\ell d(x,\bar{x})) \neq \emptyset, \quad \forall x \in B(\bar{x},\delta);
\]

the value \( Liplsc \Phi(\bar{x},\bar{y}) = \inf\{ \ell > 0 : \exists \delta > 0 \text{ for which (2.1) holds} \} \) is called *modulus of Lipschitz lower semicontinuity* of \( \Phi \) at \( (\bar{x},\bar{y}) \).

2. **Calm** at \((\bar{x},\bar{y}) \in \text{graph} \Phi\) if there exist positive constants \( \delta \), \( \zeta \) and \( \ell \) such that

\[
\Phi(x) \cap B(\bar{y},\zeta) \subseteq B(\Phi(\bar{x}),\ell d(x,\bar{x})), \quad \forall x \in B(\bar{x},\delta);
\]

the value \( \text{clm} \Phi(\bar{x},\bar{y}) = \inf\{ \ell > 0 : \exists \delta, \zeta > 0 \text{ for which (2.2) holds} \} \) is called *modulus of calmness* of \( \Phi \) at \( (\bar{x},\bar{y}) \).

3. **Lipschitz upper semicontinuous**\( ^1 \) at \( \bar{x} \in X \) if there exist positive constants \( \delta \) and \( \ell \) such that

\[
\Phi(x) \subseteq B(\Phi(\bar{x}),\ell d(x,\bar{x})), \quad \forall x \in B(\bar{x},\delta);
\]

\( ^1 \)A terminological warning is due: Lipschitz upper semicontinuity was introduced in [18] under the name of “outer Lipschitz continuity”, but later popularized as “outer Lipschitz continuity”, which is the name now prevailing in the literature.
the value
\[ \text{Lipusc } \Phi(\bar{x}) = \inf \{ \ell > 0 : \exists \delta > 0 \text{ for which } \text{Fact 4}\text{ holds} \} \]
is called \textit{modulus of Lipschitz upper semicontinuity} of \( \Phi \) at \( \bar{x} \).

**Example 2.2.** (i) (Bundles of linear operators) Let \((L(X,Y), \| \cdot \|_L)\) denote the Banach space of all linear bounded operators between a normed space \((X, \| \cdot \|)\) and a Banach space \((Y, \| \cdot \|))\), equipped with the operator norm \( \| \cdot \|_L \). Given a nonempty subset \( G \subseteq L(X,Y) \), define a set-valued mapping \( \Phi : X \rightharpoonup Y \) as
\[ \Phi(x) = \{ \Lambda x : \Lambda \in G \} . \]
Then, \( \Phi \) is Lipschitz l.s.c. at \((0,0)\) if \( \text{Lipusc } \Phi(0,0) \leq \inf_{\Lambda \in G} \| \Lambda \|_L \), where 0 stands for the null element in any normed space. Indeed, fixed an arbitrary \( \ell > \inf_{\Lambda \in G} \| \Lambda \|_L \), one has
\[ \text{dist}(0, \Phi(x)) = \inf_{\Lambda \in G} \text{dist}(0, \Lambda x) = \inf_{\Lambda \in G} \| \Lambda x \| \leq \inf_{\Lambda \in G} \| \Lambda \|_L \cdot \| x \| < \ell \| x \| , \quad \forall x \in X , \]
which implies
\[ \Phi(x) \cap B(0, \ell \| x \| ) \neq \emptyset , \quad \forall x \in X . \]

(ii) Any element \( \Lambda \in L(X,Y) \) is calm at every point \((\bar{x}, \Lambda \bar{x}) \in \text{graph } \Lambda \), with \( \text{clm } \Lambda(\bar{x}, \Lambda \bar{x}) = \| \Lambda \|_L \).

(iii) (Polyhedral finite-dimensional set-valued mappings) A set-valued mapping \( \Phi : \mathbb{R}^n \rightharpoonup \mathbb{R}^m \) is said to be polyhedral if \( \text{graph } \Phi \) is the union of finitely many polyhedral convex subsets of \( \mathbb{R}^n \times \mathbb{R}^m \).
It has been proved in \[18\] that any polyhedral mapping \( \Phi \), with \( \text{dom } \Phi = \mathbb{R}^n \), is Lipschitz u.s.c. at every point of \( \mathbb{R}^n \). A remarkable consequence of the above result is that the solution mapping to any finite-dimensional parameterized linear variational inequality turns out to be Lipschitz u.s.c. (see \[7\], Exercise 3D.2).

For the purposes of the present analysis, the following well-known facts, concerning the properties presented in Definition 2.1, are worth being mentioned. The resulting scheme should help a reader to assess the impact of the subsequent investigations and to catch connections with several recent lines of development within variational analysis.

- **Fact 1.** By elementary examples, one can show that Lipschitz lower semicontinuity and calmness are properties independent of each other.
- **Fact 2.** The Lipschitz upper semicontinuity of \( \Phi \) at \( \bar{x} \) implies calmness of \( \Phi \) at each point \((\bar{x}, y)\), with \( y \in \Phi(\bar{x}) \), and the inequality \( \cld \Phi(\bar{x}, y) \leq \text{Lipusc } \Phi(\bar{x}) \) holds for every \( y \in \Phi(\bar{x}) \) (immediate consequence of the involved definitions).
- **Fact 3.** Whenever \( \Phi \) happens to be single-valued in a neighbourhood of \( \bar{x} \), all the three properties presented in Definition 2.1 collapse to what is known under the name of calmness for single-valued mappings, namely
\[ d(\Phi(x), \Phi(\bar{x})) \leq \ell d(x, \bar{x}) ; \quad \forall x \in B(\bar{x}, \delta) \]
(immediate consequence of the involved definitions).
- **Fact 4.** In the special case in which \( \Phi \) is a single-real-valued function, the notion of calmness can be split, by considering calmness from above and calmness from below. More precisely, \( \Phi : X \rightarrow \mathbb{R} \cup \{ \pm \infty \} \) is said to be \textit{calm from above} at \( \bar{x} \in \text{dom } \Phi \) provided that there exist positive \( \delta \) and \( \ell \) such that
\[ \Phi(x) - \Phi(\bar{x}) \leq \ell d(x, \bar{x}) , \quad \forall x \in B(\bar{x}, \delta) . \]
The value
\[ \text{clm } \Phi(\bar{x}) = \inf \{ \ell > 0 : \exists \delta > 0 \text{ for which } \text{Fact 4} \text{ holds} \} \]
is called \textit{modulus of calmness from above of } \Phi \text{ at } \bar{x} \text{ (see } \text{[19] Chapter 8.F})]. The version from below of calmness, along with its modulus denoted by \( \text{clm } \Phi(\bar{x}) \), is defined in an analogous way. Note that, as far as working with single-valued mappings, calmness implies continuity, as well as calmness from above/below implies the corresponding (topological) semicontinuity property at the same point.
- **Fact 4.** If \( \Phi : X \rightrightarrows Y \) is Lipschitz l.s.c. at \((\bar{x}, \bar{y})\), then its inverse mapping \( \Phi^{-1} : Y \rightrightarrows X \) is hemiregular (alias, semiregular) at \((\bar{y}, \bar{x})\), as understood in \[5\], \[13\], \[15\], \[21\].
• **Fact 5.** If \( \Phi : X \rightrightarrows Y \) is calm at \((\bar{x}, \bar{y})\), then its inverse mapping \( \Phi^{-1} : Y \rightrightarrows X \) is metrically subregular at \((\bar{y}, \bar{x})\) (see [7] Theorem 3H.3, [11] Proposition 2.65).

• **Fact 6.** A set-valued mapping \( \Phi : X \rightrightarrows Y \) between metric spaces is called locally Lipschitz near \( \bar{x} \in X \), provided that there exist positive constant \( \delta \) and \( \ell \), such that

\[
\text{haus}(\Phi(x_1), \Phi(x_2)) = \max\{\text{exc}(\Phi(x_1), \Phi(x_2)), \text{exc}(\Phi(x_2), \Phi(x_1))\} 
\leq \ell d(x_1, x_2), \quad \forall x_1, x_2 \in B(\bar{x}, \delta),
\]

where \( \text{exc}(A, B) = \sup_{a \in A} \text{dist}(a, B) \) stands for the excess of the set \( A \) beyond the set \( B \), with \( A \) and \( B \) being subsets of the same metric space. The value

\[
\text{Lip}(\Phi(\bar{x})) = \inf \{ \ell > 0 : \exists \delta > 0 \text{ for which (2.5) holds} \}
\]

is called modulus of local Lipschitz continuity of \( \Phi \) around \( \bar{x} \). It is clear that any mapping \( \Phi \), which is locally Lipschitz near \( \bar{x} \), is Lipschitz u.s.c. at \( \bar{x} \), with Lipusc \( \Phi(\bar{x}) \leq \text{Lip}(\Phi(\bar{x})) \).

Whenever inequality in (2.5) remains true with the same \( \ell > 0 \) for every \( \delta > 0 \), \( \Phi \) is said to be Lipschitz continuous on \( X \), and the related modulus is denoted by Lip\( \Phi(\bar{x}) \).

• **Fact 7.** Calmness for set-valued mappings is always implied by Aubin continuity (a.k.a. Lipschitz like-ness), which is a manifestation of the phenomenon of metric regularity playing a fundamental role in modern variational analysis (see [7]).

Valuable historical comments on the genesis, the development and the successful applications of all the notions in Definition 2.1 from the viewpoint of some among the major contributors to the existing theory, can be found in [3, 7, 11, 12, 14, 16, 17, 19].

An aspect that makes impossible any direct comparison of the properties in Definition 2.1(i) and (ii) with purely topological semicontinuity properties and with the properties based on the Painlevé-Kuratowski convergence (see [7, Chapter 3A]), when revisited in metric spaces, is the reference to a point of the graph, instead of to a point in the definition space. The next example reveals that the notion in Definition 2.1(iii) and the Pompeiu-Hausdorff continuity are independent of each other, as one expects. According to [11, Chapter 3B] a set-valued mapping between metric spaces \( \Phi : X \rightrightarrows Y \) is said to be Pompeiu-Hausdorff continuous at \( \bar{x} \in \text{dom} \Phi \) if

\[
\lim_{x \to \bar{x}} \text{haus}(\Phi(x), \Phi(\bar{x})) = 0.
\]

**Example 2.3.** (i) (Pompeiu-Hausdorff continuity witout Lipschitz upper semicontinuity) Let \( X = Y = \mathbb{R} \) be equipped with its Euclidean metric structure. Define a set-valued mapping \( \Phi : \mathbb{R} \rightrightarrows \mathbb{R} \) as

\[
\Phi(x) = [-\sqrt{|x|}, \sqrt{|x|}],
\]

and take \( \bar{x} = 0 \). Since it is \( \Phi = \{0\} \), so \( \Phi(0) \subseteq \Phi(x) \) for every \( x \in \mathbb{R} \), and hence

\[
\text{exc}(\Phi(0), \Phi(x)) = 0, \quad \forall x \in \mathbb{R},
\]

whereas it is

\[
\text{exc}(\Phi(x), \Phi(0)) = \sqrt{|x|}, \quad \forall x \in \mathbb{R},
\]

clearly it holds \( \lim_{x \to 0} \text{haus}(\Phi(x), \Phi(0)) = 0 \). Nevertheless, since for any \( \ell > 0 \) there is no \( \delta > 0 \) such that the inequality

\[
\sqrt{|x|} \leq \ell |x|, \quad \forall x \in B(0, \delta)
\]

takes place, the inclusion

\[
\Phi(x) \subseteq B(\{0\}, \ell |x|) = [-\ell |x|, \ell |x|], \quad \forall x \in B(0, \delta),
\]

fails to be true.

(ii) (Lipschitz upper semicontinuity without Pompeiu-Hausdorff continuity) Let \( X \) and \( Y \) be as in the previous case. Define a set-valued mapping \( \Phi : \mathbb{R} \rightrightarrows \mathbb{R} \) by setting

\[
\Phi(x) = \begin{cases} 
(-\infty, 0], & \text{if } x < 0, \\
\mathbb{R}, & \text{if } x = 0, \\
[0, +\infty) & \text{if } x > 0,
\end{cases}
\]
and take \( \bar{x} = 0 \). Since \( B(\Phi(0), \ell|x|) = \mathbb{R} \) for every \( x \in \mathbb{R} \) and \( \ell > 0 \), the inclusion

\[
\Phi(x) \subseteq B(\Phi(0), \ell|x|) = \mathbb{R}, \quad \forall x \in B(0, \delta)
\]

is evidently satisfied for every \( \ell, \delta > 0 \). Nonetheless, since it is \( \text{exc}(\Phi(0), \Phi(x)) = +\infty \) for every \( x \in \mathbb{R}\setminus\{0\} \), one has \( \lim_{x \to 0} \text{haus}(\Phi(x), \Phi(0)) = +\infty \neq 0 \).

The analysis of the properties recalled in Definition 2.1 will be performed in the case of the set-valued mapping \( S : P \rightrightarrows X \), describing the solution stability of problems \((SVI_p)\) under parameter perturbation. Since all of them have a purely metric nature, it seems to be natural, at a first step, to approach this question “iuxta propria principia”, namely in a metric space setting. A way to accomplish such a task relies on the excess function that can be associated to a problem \((SVI_p)\), i.e. the functional \( \varphi_F : X \to \mathbb{R} \cup \{\pm \infty\} \), defined as

\[
\varphi_F(p, x) = \text{exc}(F(p, x), C).
\]

Such an approach enables one to characterize the solution of a \((SVI_p)\) problem as a zero of \( \varphi_F(p, \cdot) \), according to a successful strategy in addressing different variational problems, even in their metric space formulation. In fact, modern variational analysis offers a well developed apparatus of tools and techniques for carrying out a quantitative study of the stability properties of zeroes of functionals. The remaining part of the present section is devoted to gather all those elements of set-valued and variational analysis, which are needed to implement this approach in the subsequent sections. Let us start with a lemma that links semicontinuity properties of a set-valued mapping \( \Phi : X \rightrightarrows Y \) with those of the related excess function \( \varphi_\Phi : X \to \mathbb{R} \cup \{\pm \infty\} \).

**Lemma 2.4.** Let \( \Phi : X \rightrightarrows Y \) be a set-valued mapping between metric spaces and let \( C \subseteq Y \) be a nonempty closed set. Define \( \varphi_\Phi : X \to \mathbb{R} \cup \{\pm \infty\} \) as \( \varphi_\Phi(x) = \text{exc}(\Phi(x), C) \).

(i) If \( \Phi \) is l.s.c. at \( \bar{x} \), then \( \varphi_\Phi \) is l.s.c. at the same point.

(ii) If \( \Phi \) is Lipschitz u.s.c. at \( \bar{x} \), then \( \varphi_\Phi \) is calm from above at the same point and

\[
\overline{\text{clm}} \varphi_\Phi(\bar{x}) \leq \text{Lipusc } \Phi(\bar{x}).
\]

In particular, under hypothesis (ii), \( \varphi_\Phi \) is u.s.c. at \( \bar{x} \).

**Proof.** (i) The proof is given in full detail in [22, Lemma 2.3], upon the assumptions that \( Y \) is a normed space and \( C \) is a closed, convex cone of it. A perusal of the argument employed there reveals that neither the convexity of \( C \) nor the linear structure of \( C \) are actually exploited in the proof, relying instead on basic definitions and inequalities valid in any metric space.

(ii) Take an arbitrary \( \ell > \text{Lipusc } \Phi(\bar{x}) \). Then, there exists \( \delta > 0 \) such that inclusion (2.3) holds. Consequently, by using the triangular inequality for the excess, one obtains

\[
\varphi_\Phi(x) = \text{exc}(\Phi(x), C) \leq \text{exc}(\Phi(x), \Phi(\bar{x})) + \text{exc}(\Phi(\bar{x}), C) \leq \ell d(x, \bar{x}) + \varphi_\Phi(\bar{x}), \quad \forall x \in B(\bar{x}, \delta).
\]

This shows that \( \varphi_\Phi \) is calm from above at \( \bar{x} \) and that \( \overline{\text{clm}} \varphi_\Phi(\bar{x}) \leq \ell \). The estimate in (2.6) is true because of the arbitrariness of \( \ell > \text{Lipusc } \Phi(\bar{x}) \).

The last statement in the thesis is a consequence of Fact 3. \( \square \)

**Remark 2.5.** In several circumstances, it will be proper to work with an excess function \( \varphi_\Phi \), which is real valued on \( X \). It is readily seen that this happens if the following assumptions are taken on \( \Phi \):

(i) \( \text{dom } \Phi = X \) (so that \( \varphi_\Phi(X) \subseteq [0, +\infty] \));

(ii) the set-valued mapping \( \Phi \) is **bounded-valued away from** the set \( C \), meaning that for every \( x \in X \) the set \( \Phi(x) \setminus C \) is bounded as a subset of a metric space (so that \( \varphi_\Phi(x) < +\infty \), for every \( x \in X \)).

In order to formalize the differential conditions, upon which Lipschitz semicontinuity properties of \( S \) will be established, the notion of strict outer slope plays a crucial role. Such tool of analysis in metric spaces can be presented as a regularization of the well-known notion of (strong) slope, which
was introduced in [6]. Given a function \( \psi : X \longrightarrow \mathbb{R} \cup \{ \pm \infty \} \), defined on a metric space \((X, d)\), and \( \bar{x} \in \psi^{-1}(\mathbb{R}) \), the real-extended value

\[
|\nabla \psi|_{\bar{x}} = \begin{cases} 
0, & \text{if } \bar{x} \text{ is a local minimizer for } \psi, \\
\limsup_{x \to \bar{x}} \frac{\psi(x) - \psi(\bar{x})}{d(x, \bar{x})}, & \text{otherwise},
\end{cases}
\]

is called (strong) slope of \( \psi \) at \( \bar{x} \). The real-extended value

\[
|\nabla \psi|_{\bar{x}}^+ = \lim_{\epsilon \to 0^+} \inf \{|\nabla \psi| : x \in B(\bar{x}, \epsilon), \ \psi(x) < \psi(\bar{x}) < \psi(\bar{x}) + \epsilon\}
\]

is called strict outer slope of \( \psi \) at \( \bar{x} \).

**Example 2.6.** (i) It is well known that, whenever a function \( \psi : X \longrightarrow \mathbb{R} \cup \{ \pm \infty \} \), defined on a Banach space, is Fréchet differentiable at \( x \in \psi^{-1}(\mathbb{R}) \), with Fréchet derivative \( D\psi(x) \), then its strong slope at \( x \) can be readily calculated as \( |\nabla \psi|_{x} = ||D\psi(x)|| \) (see, for instance, [10, Chapter 1.2]).

(ii) In view of the analysis exposed in Section 5, it is useful to mention that for a function \( \psi : X \longrightarrow \mathbb{R} \cup \{ \pm \infty \} \) defined in a Banach space, which is l.s.c. and convex, it holds

\[
|\nabla \psi|_{x} = \text{dist} (0^*, \partial \psi(x)), \quad \forall x \in \psi^{-1}(\mathbb{R}),
\]

where \( \partial \psi(x) \) denotes the subdifferential of \( \psi \) at \( x \), in the sense of convex analysis, and \( 0^* \) stands for the null element of the dual space \( X^* \) to \( X \). In such case, the value \( \text{dist} (0^*, \partial \psi(x)) \) is often referred to as the subdifferential slope of \( \psi \) at \( x \) (see, for instance, [8, Theorem 5]).

For further reading on the theme of strong slope and its several variations the reader is referred to [11, Chapter 3.1.2], [8] and [17, Chapter 1.6].

### 3. Conditions for Lipschitz Semicontinuity of \( \mathcal{S} \)

Throughout the current section, the equality \( \text{dom} F = P \times X \) will be kept in force as a standing assumption on the set-valued mapping \( F \), which will be supposed also to take closed values. Before discussing the Lipschitz semicontinuity properties of \( \mathcal{S} \), it is worthwhile to come back to equality

\[
(3.1) \quad \mathcal{S}(p) = [\varphi_F(p, \cdot) \leq 0] = F(p, \cdot)^{+1}(C).
\]

A topological consequence of it is that, whenever the set-valued mapping \( F(p, \cdot) : X \rightrightarrows Y \) is supposed to be l.s.c. on \( X \) for every fixed \( p \in P \), the set \( \mathcal{S}(p) = X \setminus [\varphi_F(p, \cdot) > 0] \) is closed (possibly, empty), by virtue of the lower semicontinuity of the functional \( \varphi_F(p, \cdot) \) (remember Lemma 2.3(i)). Thus, upon the above condition, \( \mathcal{S} \) be turns out to be closed-valued.

In the statement of the next result, the following partial version of the strict outer slope will be employed:

\[
(3.2) \quad |\nabla_x \varphi_F|_{\bar{p}, \bar{x}} = \lim_{\epsilon \to 0^+} \inf \{|\nabla \varphi_F(p, \cdot)|(x) : (p, x) \in B(\bar{p}, \epsilon) \times B(\bar{x}, \epsilon), \ \varphi_F(p, x) < \varphi_F(\bar{p}, \bar{x}) + \epsilon\}.
\]

**Theorem 3.1** (Lipschitz lower semicontinuity of \( \mathcal{S} \)). With reference to a parameterized set-valued inclusion \((SVI_p)\), let \( \bar{p} \in P \) and let \( \bar{x} \in \mathcal{S}(\bar{p}) \). Suppose that:

(i) \((X, d)\) is metrically complete;
(ii) the mapping \( F(\cdot, \bar{x}) : P \rightrightarrows Y \) is Lipschitz u.s.c. at \( \bar{p} \);
(iii) there exists \( \delta > 0 \) such that, for every \( p \in B(\bar{p}, \delta) \), each mapping \( F(p, \cdot) : X \rightrightarrows Y \) is l.s.c. on \( X \);
(iv) it holds \( |\nabla_x \varphi_F|_{\bar{p}, \bar{x}} > 0 \).

Then, the solution mapping \( \mathcal{S} : P \rightrightarrows X \) is Lipschitz l.s.c. at \((\bar{p}, \bar{x})\) and the following estimate holds

\[
(3.3) \quad \text{Lip l.s.c}\mathcal{S}(\bar{p}, \bar{x}) \leq \frac{\text{Lipusc} F(\cdot, \bar{x})(\bar{p})}{|\nabla_x \varphi_F|_{\bar{p}, \bar{x}}^+}.
\]
By the Ekeland variational principle, corresponding to
\[ |\nabla_x \varphi_F|^{\sigma} (\bar{p}, \bar{x}) > \sigma > 0. \]

According to the definition of strict outer slope, the above inequality means that there exists \( \eta > 0 \)
such that for every \( \epsilon \in (0, \eta) \) it holds
\[ (3.4) \quad |\nabla \varphi_F(p, \cdot)(x)| > \sigma, \quad \forall (p, x) \in B(\bar{p}, \epsilon) \times B(\bar{x}, \epsilon) : 0 < \varphi_F(p, x) < \epsilon. \]

Without any loss of generality, it is possible to assume that \( \eta < \delta \), where \( \delta \) is as in hypothesis (iii).

Under the current assumptions, the above properties allow one to show that it is 
\( \varphi_F(p, x) \leq \varphi_F(\bar{p}, \bar{x}) + \ell d(p, \bar{p}) = \ell d(p, \bar{p}), \quad \forall p \in B(\bar{p}, \delta). \)

Notice that, by reducing its value if needed, it is possible to pick \( \delta_\ell \) in such a way that
\[ (3.5) \quad \varphi_F(p, \bar{x}) \leq \varphi_F(\bar{p}, \bar{x}) + \ell d(p, \bar{p}) = \ell d(p, \bar{p}), \quad \forall p \in B(\bar{p}, \delta_\ell). \]

By the Ekeland variational principle, corresponding to
\[ \lambda = \frac{\ell d(p, \bar{p})}{\sigma}, \]
there exists \( x_\lambda \in X \) with the following properties:
\[ (3.7) \quad \varphi_F(p, x_\lambda) \leq \varphi_F(p, \bar{x}) \leq \ell d(p, \bar{p}), \]
\[ (3.8) \quad d(x_\lambda, \bar{x}) \leq \lambda, \]
and
\[ (3.9) \quad \varphi_F(p, x_\lambda) < \varphi_F(p, x) + \sigma d(x, x_\lambda), \quad \forall x \in X \setminus \{x_\lambda\}. \]

Under the current assumptions, the above properties allow one to show that it is \( \varphi_F(p, x_\lambda) = 0 \).

Indeed, suppose, ab absurdo, that it is \( \varphi_F(p, x_\lambda) > 0 \). As a consequence of inequality (3.9), one has
\[ \frac{\varphi_F(p, x_\lambda) - \varphi_F(p, x)}{d(x, x_\lambda)} < \sigma, \quad \forall x \in X \setminus \{x_\lambda\}, \]
whence one obtains
\[ (3.10) \quad |\nabla \varphi_F(p, \cdot)(x_\lambda)| = \lim_{r \to 0^+} \sup_{x \in B(x_\lambda, r) \setminus \{x_\lambda\}} \frac{\varphi_F(p, x_\lambda) - \varphi_F(p, x)}{d(x, x_\lambda)} \leq \sigma. \]

On the other hand, by recalling inequality (3.6), one sees that
\[ (3.11) \quad d(p, \bar{p}) \leq \delta_\ell < \frac{\eta}{2}, \]
and, on account of inequality (3.8),
\[ (3.12) \quad d(x_\lambda, \bar{x}) \leq \frac{\ell d(p, \bar{p})}{\sigma} < \frac{\ell}{\sigma} \cdot \frac{\sigma \eta}{2(\ell + 1)} < \frac{\eta}{2}. \]

Besides, because of inequalities (3.6) and (3.7), it is true that
\[ (3.13) \quad \varphi_F(p, x_\lambda) \leq \ell \delta_\ell < \frac{\eta}{2(\ell + 1)} < \frac{\eta}{2}. \]
Inequality (3.10), along with inequalities (3.11), (3.12), and (3.13), contradicts (3.4) if taking \( \epsilon = \eta / 2 \). The above argument proves that it is actually \( \varphi_{F}(p, x_{\lambda}) = 0 \), which means that \( F(p, x_{\lambda}) \subseteq C \), and hence \( x_{\lambda} \in S(p) \). Since it is \( d(x_{\lambda}, \bar{x}) \leq \frac{\ell(d(p, \bar{p}))}{\sigma} \), it results in
\[
S(p) \cap B \left( \bar{x}, \frac{\ell(d(p, \bar{p}))}{\sigma} \right) \neq \emptyset.
\]

By arbitrariness of \( p \in B(\bar{p}, \delta) \setminus \{\bar{p}\} \), the last relation amounts to say that \( S \) is Lipschitz l.s.c. at \( (\bar{p}, \bar{x}) \), and it holds
\[
\text{Lipusc} S(\bar{p}, \bar{x}) \leq \frac{\ell}{\sigma}.
\]

The arbitrariness of \( \ell > \text{Lipusc} F(\cdot, \bar{x})(\bar{p}) \) and of \( \sigma < \| \nabla_{x} \varphi_{F} \| \sigma (\bar{p}, \bar{x}) \) enables one to achieve the estimate in the thesis, thereby completing the proof. \( \square \)

The reader should notice that Theorem 3.1 provides a condition for the local solvability of problems \((SVF_{\lambda})\) under parameter perturbation. Furthermore, through the estimate (3.3), it affords quantitative information on the stability of the solution mapping. Unfortunately, as happens for many implicit function theorems, the differential condition upon which it can be established (hypothesis (iv) in Theorem 3.1) is only sufficient. This fact is illustrated by the next example.

**Example 3.2.** Let \( P = X = Y = \mathbb{R} \) be endowed with its usual Euclidean metric structure, let \( C = [0, +\infty) \) and let \( F : \mathbb{R} \times \mathbb{R} \to \mathbb{R} \) be defined by
\[
F(p, x) = [p^{3} + x^{3}, +\infty).
\]

Since \( F(p, x) \subseteq C \) if \( p^{3} + x^{3} = (p + x)(p^{2} - px + x^{2}) \geq 0 \), in this case the solution mapping \( S : \mathbb{R} \rightrightarrows \mathbb{R} \) associated with the inclusion problem takes the simple form
\[
S(p) = [-p, +\infty), \quad \forall p \in \mathbb{R}.
\]

In particular, one sees that, letting \( \bar{p} = \bar{x} = 0 \), it is \( 0 \in S(0) \). Since \( F \) is the epigraphical set-valued mapping related to the continuous function \( (p, x) \mapsto p^{3} + x^{3} \), it is l.s.c. on \( \mathbb{R} \times \mathbb{R} \). As a consequence, there exists \( \delta > 0 \) such that each set-valued mapping \( x \rightsquigarrow F(p, x) \) is l.s.c. on \( \mathbb{R} \), for every \( p \in B(0, \delta) \). To check the Lipschitz lower semicontinuity of the set-valued mapping \( p \rightsquigarrow F(p, 0) = [p^{3}, +\infty) \) mentioned in the hypothesis (ii) of Theorem 3.1 observe that
\[
F(p, 0) \subseteq F(0, 0) = [0, +\infty), \quad \forall p \geq 0.
\]

For any \( p \in (0, 1) \), as it is \( p^{3} > -|p| \), one finds
\[
F(p, 0) = [p^{3}, +\infty) \subseteq [-|p|, +\infty) = B(F(0, 0), |p|).
\]

Thus, the set-valued mapping \( p \rightsquigarrow F(p, 0) = [p^{3}, +\infty) \) is Lipschitz u.s.c. at \( 0 \), with \( \text{Lipusc} F(\cdot, 0)(0) \leq 1 \). It is readily seen that the function \( \varphi_{F} : \mathbb{R} \times \mathbb{R} \to \mathbb{R} \) is given in the present circumstance by
\[
\varphi_{F}(p, x) = \begin{cases} 0, & (p, x) \in \mathbb{R} \times \mathbb{R} : \ p + x \geq 0, \\ -(p^{3} + x^{3}), & (p, x) \in \mathbb{R} \times \mathbb{R} : \ p + x < 0. \end{cases}
\]

Recalling the strong slope estimate remarked in Example 2.6(1), one has
\[
|\nabla \varphi_{F}(p, \cdot)(x)| = \left| \frac{\partial}{\partial x} \varphi_{F}(p, x) \right| = \begin{cases} 0, & (p, x) \in \mathbb{R} \times \mathbb{R} : \ p + x > 0, \\ 3x^{2}, & (p, x) \in \mathbb{R} \times \mathbb{R} : \ p + x < 0. \end{cases}
\]

Consequently, according to the definition of strict outer slope, one finds
\[
|\nabla \varphi_{F}^{-}(0, 0)| = 0,
\]

because points \((p, x)\) such that \( p + x < 0 \) and \( x = 0 \) (hence such that \(|\nabla \varphi_{F}^{-}(p, x) = 0\)) can be found in each set \( ((-\epsilon, \epsilon) \times (-\epsilon, \epsilon)) \cap \{(p, x) \in \mathbb{R} \times \mathbb{R} : \ 0 < -(p^{3} + x^{3}) < \epsilon\} \), with \( \epsilon > 0 \). This shows that hypothesis (iv) of Theorem 3.1 is not satisfied. Nonetheless, the mapping \( S \) turns out to be Lipschitz l.s.c. at \((0, 0)\). Indeed, directly from the expression of \( S \), one sees that
\[
S(p) \cap B(0, |p|) \neq \emptyset, \quad \forall p \in \mathbb{R},
\]
Thus, it is

By applying the Ekeland variational principle, one can assert that, corresponding to the value

The inequality (3.19) implies

Now, fix an arbitrary $p \in P$ and let $\bar{x} \in S(\bar{p})$. Suppose that:

(i) $(X,d)$ is metrically complete;
(ii) the set-valued mapping $F(\bar{p}, \cdot) : X \rightrightarrows Y$ is l.s.c. on $X$;
(iii) the mapping $F$ is locally Lipschitz near $(\bar{p},\bar{x})$;
(iv) it holds $|\nabla \varphi_F(\bar{p},\cdot)| > (\bar{x}) > 0$.

Then, the solution mapping $S : P \rightrightarrows X$ is calm at $(\bar{p}, \bar{x})$ and the following estimate holds

Proof. According to hypothesis (iii), taken an arbitrary $\ell > \text{Lip}(\bar{p}, \bar{x})$ there must exist $\delta > 0$ such that

there exists $\eta > 0$ such that, for every $\epsilon \in (0, \eta)$, it holds

According to hypothesis (iv), taken any $\sigma > 0$ such that

Let us take positive reals $\delta_\epsilon$ and $\zeta$ in such a way that

Now, fix an arbitrary $p \in B(\bar{p}, \delta_\epsilon) \setminus \{\bar{p}\}$. If $S(p) \cap B(\bar{x}, \zeta) = \emptyset$, then nothing is left to prove. Otherwise, take an arbitrary $x_p \in S(p) \cap B(\bar{x}, \zeta)$. Consider the function $\varphi(p, \cdot) : X \rightarrow [0, +\infty[$. By virtue of hypothesis (ii), Lemma 2.4(i) ensures that this function is l.s.c. on $X$. It is clearly bounded from below. Since $d(x_p, \bar{x}) \leq \zeta < \delta$ and $d(p, \bar{p}) \leq \delta_\epsilon < \delta$, from inequality (3.14) and the triangular inequality for the excess, it follows

Thus, it is

By applying the Ekeland variational principle, one can assert that, corresponding to the value

there exists $x_\lambda \in X$, satisfying the below properties:

and

The inequality (3.19) implies

wherefrom it follows

$$|\nabla \varphi_F(\bar{p}, \cdot)(x)| \leq \sigma.$$
The last inequality entails that it must be $\varphi_F(\bar{p}, x_\lambda) = 0$. Indeed, if supposing $\varphi_F(\bar{p}, x_\lambda) > 0$, by recalling the choice of $\delta_\lambda$ and $\zeta$ in (3.10), along with inequality (3.17), one obtains

$$\varphi_F(\bar{p}, x_\lambda) \leq \ell d(p, \bar{p}) < \eta$$

and

$$d(x_\lambda, \bar{x}) \leq d(x_\lambda, x_p) + d(x_p, \bar{x}) \leq \lambda + \zeta \leq \frac{\ell d(p, \bar{p})}{\sigma} + \zeta < \frac{\eta}{4} + \frac{\eta}{4} = \frac{\eta}{2}.$$  

Thus, inequality (3.15) turns out to be contradicted with $\epsilon = \eta/2$. The fact that it is $\varphi_F(\bar{p}, x_\lambda) = 0$ implies $x_\lambda \in S(\bar{p})$. By taking into account inequality (3.18), one finds

$$\text{dist } (x_p, S(\bar{p})) \leq d(x_p, x_\lambda) \leq \frac{\ell d(p, \bar{p})}{\sigma},$$

which amounts to say that $x_p \in B(S(\bar{p}), \ell d(p, \bar{p})/\sigma)$. By arbitrariness of $x_p \in S(p) \cap B(\bar{x}, \zeta)$ and $\bar{p} \in B(\bar{p}, \delta_\lambda) \setminus \{\bar{p}\}$, the above argument shows that $S$ is calm at $(\bar{p}, \bar{x})$, with $\text{clm } S(\bar{p}, \bar{x}) \leq \ell/\sigma$. The arbitrariness of $\ell > \text{Lip}(F(\bar{p}, \bar{x})$ and of $\sigma < |\nabla \varphi_F(\bar{p}, \bar{p})| \bar{\gamma}(\bar{x})$ leads to achieve the estimate in the thesis, thereby completing the proof. \hfill \Box

In the same vein of Example 3.2 the next counterexample shows that condition (iv) in Theorem 3.3 is far from being necessary.

**Example 3.4.** Let us consider the same inclusion problem introduced in Example 3.2. As a continuously differentiable function, $(p, x) \mapsto p^3 + x^3$ is strictly differentiable at $(\bar{p}, \bar{x}) = (0,0)$, and hence locally Lipschitz near that point. Consequently, $F$ is locally Lipschitz near $(0, 0)$. Since it is

$$\varphi_F(0, x) = \begin{cases} 0, & \text{if } x \geq 0, \\ -x^3, & \text{if } x < 0, \end{cases}$$

it results in

$$|\nabla \varphi_F(0, \cdot)| \bar{\gamma}(0) = \lim_{\epsilon \to 0^+} \inf \{ |\nabla \varphi_F(0, \cdot)|(x) : x \in [-\epsilon, \epsilon], 0 < \varphi_F(0, x) < \epsilon \}$$

$$= \lim_{\epsilon \to 0^+} \inf \{ 3x^2 : x \in [-\epsilon, 0] \} = 0.$$  

Thus, hypothesis (iv) of Theorem 3.3 fails to be fulfilled. In spite of such a failure, the solution mapping $S : \mathbb{R} \rightrightarrows \mathbb{R}$ associated with the inclusion problem is not only calm at $(0, 0)$, but even Lipschitz continuous on $\mathbb{R}$.

As a further comment to the so far exposed results, it is to be noted that the differential conditions appearing in Theorem 3.1 and in Theorem 3.3 are different. Indeed, whereas both of them are built by means of the partial slope with respect to the variable $x$, the condition (iv) in Theorem 3.1 considers the $\lim_{\epsilon \to 0^+}$ regularization, with both $p$ and $x$ varying near $\bar{p}$ and $\bar{x}$, respectively. In contrast to this, condition (iv) in Theorem 3.3 requires only $x$ to vary near $\bar{x}$, while it is kept $p = \bar{p}$.

In view of the formulation of the last result of this section, given $F : P \times X \rightrightarrows Y$ and $\bar{p} \in P$, let us define the value

$$\tau_{\bar{p}} = \inf \{ |\nabla \varphi_F(\bar{p}, \cdot)|(x) : x \in X \setminus S(\bar{p}) \}.$$

**Theorem 3.5 (Lipschitz upper semicontinuity of $S$).** With reference to a parameterized set-valued inclusion (SVIL$_p$), let $\bar{p} \in P$, with $S(\bar{p}) \neq \emptyset$. Suppose that:

(i) $(X, d)$ is metrically complete;

(ii) the set-valued mapping $F(\bar{p}, \cdot) : X \rightrightarrows Y$ is l.s.c. on $X$;

(iii) the mapping $F$ is locally Lipschitz near $\bar{p}$ with respect to $p$, uniformly in $x \in X$;

(iv) it is $\tau_{\bar{p}} > 0$.

Then, the solution mapping $S : P \rightrightarrows X$ is Lipschitz u.s.c. at $\bar{p}$ and the following estimate holds

$$\text{Lip}_{\bar{p}} S(\bar{p}) \leq \frac{\text{Lip}_p F(\bar{p}, X)}{\tau_{\bar{p}}}.$$
Proof. By virtue of hypothesis (iv), it is possible to pick any \( \tau \in (0, \tau_\bar{p}) \). According to hypothesis (iii), taken any positive \( \ell > \text{Lip}_\bar{p} F(\bar{p}, X) \), there exists \( \delta > 0 \) such that

\[
\text{haus}(F(p_1, x), F(p_2, x)) \leq \ell d(p_1, p_2), \quad \forall p_1, p_2 \in B(\bar{p}, \delta), \quad \forall x \in X.
\]

Fix an arbitrary \( p \in B(\bar{p}, \delta) \setminus \{\bar{p}\} \). If \( S(p) = \emptyset \), the inclusion

\[
S(p) \subseteq B \left( S(\bar{p}), \frac{\ell}{\tau} d(p, \bar{p}) \right)
\]

is trivially satisfied. Otherwise, take an arbitrary \( x_\bar{p} \in S(p) \). Consider the function \( \varphi_F(\bar{p}, \cdot) : X \rightarrow [0, +\infty] \). By virtue of hypothesis (ii), Lemma 2.4(i) ensures that this function is l.s.c. on \( X \). It is clearly bounded from below. Besides, since it is \( F(p, x_\bar{p}) \subseteq C \), on account of inequality (3.20) one obtains

\[
\varphi_F(\bar{p}, x_\bar{p}) = \text{exc} (F(\bar{p}, x_\bar{p}), C) \leq \text{exc} (F(\bar{p}, x_\bar{p}), F(p, x_\bar{p})) + \text{exc} (F(p, x_\bar{p}), C) \leq \ell d(p, \bar{p}),
\]

so that

\[
\varphi_F(\bar{p}, x_\bar{p}) \leq \inf_{x \in X} \varphi_F(\bar{p}, x) + \ell d(p, \bar{p}).
\]

By applying the Ekeland variational principle, with

\[
\lambda = \frac{\ell d(p, \bar{p})}{\tau}
\]

and proceeding along the same lines as in the proof of Theorem 3.3 with obvious adaptations, one can reach immediately all assertions in the thesis. \( \square \)

As a comment to Theorem 3.3, let us note that, since it is

\[
\left| \nabla \varphi_F(\bar{p}, \cdot) \right|(\bar{x}) \geq \tau_\bar{p},
\]

then condition \( \tau_\bar{p} > 0 \) is stricter than condition (iv) in Theorem 3.3. Consistently, the thesis of Theorem 3.3 guarantees a stronger property for \( S \) than that of Theorem 3.3 in consideration of Fact 2.

4. Consequences on the value analysis in parametric optimization

Let \( \vartheta : P \times X \rightarrow \mathbb{R} \) be a given function defined on the Cartesian product of two metric spaces \( P \) and \( X \), and let \((\mathcal{V}I_p)\) be a given parameterized class of set-valued inclusion. In the current section, some consequences of the findings exposed in Section 3 will be presented, with reference to the analysis of the parametric class of constrained optimization problems defined by the aforementioned data, namely

\[
(P_p) \quad \min \vartheta(p, x) \quad \text{with } x \in X \quad \text{subject to} \quad F(p, x) \subseteq C.
\]

The feasible region of each problem \((P_p)\) is given by the set-valued mapping \( S : P \rightrightarrows X \), defined as in (3.1). More precisely, the investigations will focus on the calmness properties of the optimal value (alias, performance) function \( \text{val}_P : P \rightrightarrows \mathbb{R} \cup \{\pm \infty\} \), which can be associated with \((P_p)\), i.e.,

\[
\text{val}_P(p) = \inf_{x \in S(p)} \vartheta(p, x).
\]

A further element appearing in what follows is the solution mapping \( \text{Argmin} : P \rightrightarrows X \) associated with \((P_p)\), i.e.,

\[
\text{Argmin}(p) = \{ x \in S(p) : \vartheta(p, x) \leq \text{val}_P(p) \}.
\]

As one expects, in consideration of the broad spectrum of applications that a similar issue can promise, a wide literature flourished on that subject, yielding a large amount of results, often tailored on the base of the problem format. One of the key reference in the value analysis, for optimization problems with an abstract feasible region formalized by a set-valued mapping, is the so-called maximum Berge’s theorem (see [1, Theorem 17.31]), which provides a sufficient condition for the continuity of the optimal value function in a pure topological setting. Advances in this direction were obtained with [2, Theorem 3B.5]. Here a result about calmness of \( \text{val}_P \) is proposed, which is specific for the problem format \((P_p)\).

As in Section 3 throughout the current section it is assumed that \( \text{dom} \ F = P \times X \). Besides, as Cartesian product metric space, \( P \times X \) will be supposed to be equipped with the max distance. By exploiting the same arguments as in the proof of [20, Proposition 3.2] (which makes only assumptions
on \( \vartheta \) and \( \mathcal{S} \), independently on how the constraints defining \( \mathcal{S} \) are formalized), one can establish the following result, where Lipschitz lower semicontinuity plays a crucial role.

**Proposition 4.1** (Calmness from above of \( \text{val}_P \)). With reference to a parametric class of problem \( (P_p) \), let \( \bar{p} \in P \) and let \( \bar{x} \in \text{Argmin}(\bar{p}) \). Suppose that:

(i) \((X,d)\) is metrically complete;

(ii) the mapping \( F(\cdot,\bar{x}) : P \rightrightarrows Y \) is Lipschitz u.s.c. at \( \bar{p} \);

(iii) there exists \( \delta > 0 \) such that, for every \( p \in B(\bar{p},\delta) \), each set-valued mapping \( F(p,\cdot) : X \rightrightarrows Y \) is l.s.c. on \( X \);

(iv) it holds \( |\nabla_x \varphi| > (\bar{p},\bar{x}) > 0 \);

(v) function \( \vartheta : P \times X \to \mathbb{R} \) is calm from above at \((\bar{p},\bar{x})\).

Then, function \( \text{val}_P : P \to \mathbb{R} \cup \{ \pm \infty \} \) is calm from above at \( \bar{p} \) and

\[
\text{clm} \text{val}_P(\bar{p}) \leq \text{clm} \vartheta(\bar{p},\bar{x}) \cdot \max \left\{ 1, \frac{1}{\text{Lipusc} F(\cdot,\bar{x})(\bar{p})} \right\}.
\]

**Proof.** By hypothesis (v), fixed any \( \kappa > \text{clm} \vartheta(\bar{p},\bar{x}) \), there exists \( \delta > 0 \) such that

\[
\text{(4.2)} \quad \vartheta(p,x) - \vartheta(\bar{p},\bar{x}) \leq \kappa \max \{ d(p,\bar{p}), d(x,\bar{x}) \}, \quad \forall (p,x) \in B(\bar{p},\delta) \times B(\bar{x},\delta).
\]

Under hypotheses (i)-(iv), Theorem 3.3 ensures that \( \mathcal{S} \) is Lipschitz l.s.c. at \((\bar{p},\bar{x})\), with modulus satisfying inequality (3.3). Therefore, fixed any \( \ell > \text{Lipusc} F(\cdot,\bar{x})(\bar{p})/|\nabla_x \varphi|(\bar{p},\bar{x}) \), there exists \( \zeta > 0 \) such that

\[
\mathcal{S}(p) \cap B(\bar{x},\ell d(p,\bar{p})) \neq \emptyset, \quad \forall p \in B(\bar{p},\zeta).
\]

This means that, for any \( p \in B(\bar{p},\zeta) \), there must exist \( x_p \in \mathcal{S}(p) \) such that \( d(x_p,\bar{x}) \leq \ell d(p,\bar{p}) \). Without loss of generality, one can assume \( \zeta < \min \{ \delta, \delta/\ell \} \). Consequently, one has \( x_p \in B(\bar{x},\delta) \), and hence \( (p,x_p) \in B(\bar{p},\delta) \times B(\bar{x},\delta) \). This fact allows one to invoke inequality (4.2). Therefore, it follows

\[
\text{val}_P(p) - \text{val}_P(\bar{p}) \leq \vartheta(p,x_p) - \vartheta(\bar{p},\bar{x}) \leq \kappa \max \{ d(p,\bar{p}), d(x_p,\bar{x}) \}
\]

\[
\leq \kappa \cdot \max \{ 1, \ell \}, \quad \forall p \in B(\bar{p},\zeta) \setminus \bar{p}.
\]

The above inequality chain allows one to obtain

\[
\limsup_{p \to \bar{p}} \frac{\text{val}_P(p) - \text{val}_P(\bar{p})}{d(p,\bar{p})} \leq \kappa \cdot \max \{ 1, \ell \} < +\infty.
\]

This shows that the function \( \text{val}_P \) is calm from above at \( \bar{p} \), with \( \text{clm} \text{val}_P(\bar{p}) \leq \kappa \cdot \max \{ 1, \ell \} \). To conclude the proof, the inequality (4.1) can be achieved by arbitrariness of \( \kappa > \text{clm} \vartheta(\bar{p},\bar{x}) \) and of \( \ell > \text{Lipusc} F(\cdot,\bar{x})(\bar{p})/|\nabla_x \varphi|(\bar{p},\bar{x}) \).

The counterpart of the above result for the calmness from below of \( \text{val}_P \) is established next by exploiting the Lipschitz upper semicontinuity property of \( \mathcal{S} \).

**Proposition 4.2** (Calmness from below of \( \text{val}_P \)). With reference to a parametric class of problem \( (P_p) \), let \( \bar{p} \in P \) and let \( \bar{x} \in \text{Argmin}(\bar{p}) \). Suppose that:

(i) \((X,d)\) is metrically complete;

(ii) the set-valued mapping \( F(\bar{p},\cdot) : X \rightrightarrows Y \) is l.s.c. on \( X \);

(iii) the mapping \( F \) is locally Lipschitz near \( \bar{p} \) with respect to \( p \), uniformly in \( x \in X \);

(iv) it is \( \tau_\bar{p} > 0 \);

(v) function \( \vartheta : P \times X \to \mathbb{R} \) is Lipschitz continuous on \( P \times X \).

Then, function \( \text{val}_P : P \to \mathbb{R} \cup \{ \pm \infty \} \) is calm from below at \( \bar{p} \) and

\[
\text{clm} \text{val}_P(\bar{p}) \leq \frac{\text{Lip}(\vartheta, P, X) \cdot \max \left\{ 1, \frac{\text{Lipusc} F(\bar{p}, X)}{\tau_\bar{p}} \right\}}{(P_p)}.
\]
Proof. By hypothesis (v), fixed any $\kappa > \text{Lip} \vartheta(P, X)$, one has
\begin{equation}
|\vartheta(p_1, x_1) - \vartheta(p_2, x_2)| \leq \kappa \cdot \max\{d(p_1, p_2), d(x_1, x_2)\}, \quad \forall (p_1, x_1), (p_2, x_2) \in P \times X.
\end{equation}

Since under hypotheses (i)-(iv) one can invoke Theorem 3.5, the set-valued mapping $S$ turns out to be Lipschitz u.s.c. at $\bar{p}$, with $\text{Lipusc} S(\bar{p}) \leq \text{Lip} F(\bar{p}, X)/\tau_{\bar{p}}$. Accordingly, fixed $\ell > \text{Lip} F(\bar{p}, X)/\tau_{\bar{p}}$, there exists $\delta > 0$ such that
\[\text{dist} (x, S(\bar{p})) \leq \ell d(p, \bar{p}), \quad \forall p \in B(\bar{p}, \delta).\]

The last inequality means that fixed $\epsilon > 0$, for every $x \in S(p)$ there exists $z_x \in S(\bar{p})$ such that
\[d(z_x, x) \leq (\ell + \epsilon)d(p, \bar{p}), \quad \forall p \in B(\bar{p}, \delta),\]

By using inequality (4.4), one finds
\[
\vartheta(p, x) \geq \vartheta(\bar{p}, z_x) - \kappa \cdot \max\{d(p, \bar{p}), d(x, z_x)\} \\
\geq \vartheta(\bar{p}, \bar{x}) - \kappa \cdot \max\{1, (\ell + \epsilon)\}d(p, \bar{p}), \quad \forall x \in S(p), \quad \forall p \in B(\bar{p}, \delta),
\]
whence it follows
\[
\frac{\text{val}_P(p) - \text{val}_P(\bar{p})}{d(p, \bar{p})} = \frac{\inf_{x \in S(p)} \vartheta(p, x) - \vartheta(\bar{p}, \bar{x})}{d(p, \bar{p})} \\
\geq -\kappa \cdot \max\{1, (\ell + \epsilon)\} > -\infty, \quad \forall p \in B(\bar{p}, \delta) \setminus \{\bar{p}\}.
\]

By passing to the lim inf as $p \to \bar{p}$, the last inequality shows that function $\text{val}_P$ is calm from below at $\bar{p}$ and $\text{clm} \text{val}_P(\bar{p}) \leq \kappa \cdot \max\{1, (\ell + \epsilon)\}$. The arbitrariness of $\epsilon > 0$ and $\kappa > \text{Lip} \vartheta(P, X)$ allows one to achieve the estimate in (4.3), thereby completing the proof.

By combining the previous results, the following condition ensuring the calmness of $\text{val}_P$ can be achieved.

**Theorem 4.3 (Calmness of $\text{val}_P$).** With reference to a parametric class of problem $(P, p)$, let $\bar{p} \in P$ and let $\bar{x} \in \text{Argmin}(\bar{p})$. Suppose that:

(i) $(X, d)$ is metrically complete;

(ii) $F$ is locally Lipschitz near $\bar{p}$ with respect to $p$, uniformly in $x \in X$;

(iii) there exists $\delta > 0$ such that, for every $p \in B(\bar{p}, \delta)$, each $F(p, \cdot) : X \rightrightarrows Y$ is l.s.c. on $X$;

(iv) it is $\min\{|\nabla_x \varphi F|^\tau_{\bar{p}, \bar{x}}\} > 0$;

(v) function $\vartheta : P \times X \rightrightarrows \mathbb{R}$ is Lipschitz continuous on $P \times X$.

Then, function $\text{val}_P : P \times X \rightrightarrows \mathbb{R} \cup \{\pm \infty\}$ is calm at $\bar{p}$ and it holds
\begin{equation}
\text{clm} \text{val}_P(\bar{p}) \leq \text{Lip} \vartheta(P, X) \cdot \max\left\{1, \frac{\text{Lip} F(\bar{p}, X)}{\min\{|\nabla_x \varphi F|^\tau_{\bar{p}, \bar{x}}\}}\right\}.
\end{equation}

Proof. In order to prove that $\text{val}_P$ is calm at $\bar{p}$ within the proposed approach, one needs to check that, under the current hypotheses (i)-(v), it is possible to apply both Proposition 3.2 and Proposition 4.1. To this aim, let us start with observing that, if the set-valued mapping $F$ is locally Lipschitz near $\bar{p}$ with respect to $p$, uniformly in $x \in X$, then, in particular, the set-valued mapping $p \mapsto F(p, \bar{x})$ is Lipschitz u.s.c. at $\bar{p}$, with $\text{Lipusc} F(\cdot, \bar{x})(\bar{p}) \leq \text{Lip} F(\bar{p}, X)$ (remember Fact 6). Secondly, observe that hypothesis (iii) entails, in particular, that the set-valued mapping $x \mapsto F(\bar{p}, x)$ is l.s.c. on $X$. Hypothesis (iv) clearly implies that the condition (iv) of both Proposition 3.2 and Proposition 4.1 is fulfilled. Finally, the Lipschitz continuity of $\vartheta$ on $P \times X$ evidently forces the calmness from above of $\vartheta$ at $(\bar{p}, \bar{x})$, with $\text{clm} \vartheta(\bar{p}, \bar{x}) \leq \text{Lip} \vartheta(P, X)$. Thus, according to Proposition 4.1, corresponding to
\begin{equation}
\ell_1 > \text{Lip} \vartheta(P, X) \cdot \max\left\{1, \frac{\text{Lip} F(\bar{p}, X)}{|\nabla_x \varphi F|^\tau_{\bar{p}, \bar{x}}(\bar{p}, \bar{x})}\right\},
\end{equation}
there exists $\delta_1 > 0$ such that
\[
\text{val}_P(p) - \text{val}_P(\bar{p}) \leq \ell_1 d(p, \bar{p}), \quad \forall p \in B(\bar{p}, \delta_1).
\]
According to Proposition 4.2, corresponding to
\begin{equation}
\ell_2 > \text{Lip} \vartheta(P, X) \cdot \max \left\{ 1, \frac{\text{Lip}_p F(\bar{p}, X)}{\tau_{\bar{p}}} \right\}
\end{equation}
there exists \( \delta_2 > 0 \) such that
\[ \text{val}_P(p) - \text{val}_P(\bar{p}) \geq -\ell_2 d(p, \bar{p}), \quad \forall p \in B(\bar{p}, \delta_2). \]
Therefore, by setting \( \delta_0 = \min\{\delta_1, \delta_2\} \) and \( \ell_0 = \max\{\ell_1, \ell_2\} \), one can assert that
\[ |\text{val}_P(p) - \text{val}_P(\bar{p})| \leq \ell_0 d(p, \bar{p}), \quad \forall p \in B(\bar{p}, \delta_0). \]
This shows that \( \text{val}_P \) is calm at \( \bar{p} \) and that \( \text{clm} \text{val}_P(\bar{p}) \leq \ell_0. \) Since \( \ell_1 \) and \( \ell_2 \) can be chosen to be arbitrarily closed to the right term in inequalities (4.10) and (4.17), respectively, one can conclude that inequality (4.15) holds.

5. SOME SPECIAL CONDITIONS IN BANACH SPACES

Even though the differential conditions appearing in Theorem 3.1, Theorem 3.3, and Theorem 3.5 have a transparent meaning in metric spaces, they need to be further worked in view of effective employments in more structured settings. The aim of the present section is therefore to provide useful (that is, from below) estimates of the three constants (5.1)
\[ \|d\varphi_F\|_{\bar{p}}(\bar{x}), \quad \|d\varphi_F(\bar{p}, \cdot)\|_{\bar{x}}, \quad \text{and} \quad \tau_{\bar{p}}, \]
which are directly based on the problem data (\( F \) and \( C \)). A similar question already arose in the study of quantitative stability properties of the solution set to traditional generalized equations and has been solved with the aid of (sometimes, ad hoc) involved constructions of nonsmooth analysis, such as graphical derivatives, prederivatives, coderivatives, estimators (see, for instance, 2, 3, 7, 9, 11, 12, 14, 16). Because of the expression of \( \varphi_F \), existing results suitable for traditional generalized equations seem not be immediately exploitable within the proposed approach to the problem at the issue. What follows must be regarded as a first attempt to address the question, starting with basic tools of convex analysis. It is reasonable to believe that the employment of more involved constructions of nonsmooth analysis, already available, might enlarge the class of set-valued inclusions, for which useful estimates can be established, and affords deeper insights into this topic.

**Definition 5.1** (Concave mapping). A set-valued mapping \( \Phi : X \rightrightarrows Y \) between Banach spaces is said to be concave on \( X \) if it holds
\begin{equation}
\Phi(tx_1 + (1-t)x_2) \subseteq t\Phi(x_1) + (1-t)\Phi(x_2), \quad \forall x_1, x_2 \in X, \forall t \in [0, 1].
\end{equation}

**Example 5.2** (Fan). After [9], a set-valued mapping \( \Phi : X \rightrightarrows Y \) between Banach spaces is said to be a fan if all the following conditions are fulfilled:
(i) \( 0 \in \Phi(0) \);
(ii) \( \Phi(tx) = t\Phi(x), \forall x \in X \) and \( \forall t > 0 \);
(iii) \( \Phi \) takes convex values;
(iv) \( \Phi(x_1 + x_2) \subseteq \Phi(x_1)+\Phi(x_2), \forall x_1, x_2 \in X. \)
By virtue of conditions (ii) and (iv), it is clear that any fan is a positively homogeneous concave set-valued mapping. As a particular example of fan, one can consider set-valued mappings which are generated by families of linear bounded operators. More precisely, let \( G \subseteq L(X, Y) \) be a convex set weakly closed with respect to the weak topology on \( L(X, Y) \). Define
\[ \Phi_G(x) = \{ y \in Y : y = \Lambda x, \Lambda \in G \}. \]
The set-valued mapping \( \Phi_G : X \rightrightarrows Y \) is known to be a particular example of fan. Note, however, that there are fans, which can not be generated by any family of linear bounded operators. The set-valued mapping \( \Phi \) considered in Example 2.3(ii) provides an instance of such a circumstance.
For other examples of concave set-valued mappings see [23].

The next lemma shows that the assumption of concavity on a set-valued mapping \( \Phi \) entails convenient properties of the related excess function \( \varphi_\Phi \), which allow one to carry out the approach here proposed by tools of convex analysis.

**Lemma 5.3.** Let \( \Phi : X \rightarrow Y \) be a set-valued mapping between Banach spaces and let \( C \subseteq Y \) a closed, convex cone. Then,

(i) if \( \Phi \) is p.h. on \( X \), so is \( \varphi_\Phi \);

(ii) if \( \Phi \) is concave on \( X \), \( \varphi_\Phi \) is convex;

(iii) if \( \Phi \) is superlinear (positively homogeneous and concave) on \( X \), \( \varphi_\Phi \) is sublinear.

**Proof.** First of all, recall that the function \( y \mapsto \text{dist}(y, C) \), as a distance function from a convex cone, is sublinear on \( Y \).

(i) One has

\[
\varphi_\Phi(tx) = \sup_{y \in \Phi(tx)} \text{dist}(y, C) = \sup_{y \in \Phi(x)} t \text{dist}(y, C) = t \varphi_\Phi(x), \quad \forall t > 0, \forall x \in \text{dom} \, \Phi.
\]

(ii) Fix \( x_1, x_2 \in \text{dom} \, \Phi \) and \( t \in [0, 1] \). By using the concavity of \( \Phi \) and the sublinearity of function \( y \mapsto \text{dist}(y, C) \), one obtains

\[
\varphi_\Phi(tx_1 + (1-t)x_2) = \sup_{y \in \Phi(tx_1 + (1-t)x_2)} \text{dist}(y, C) \leq \sup_{y \in \Phi(x_1) + (1-t)\Phi(x_2)} \text{dist}(y, C) = \sup_{y_1 \in \Phi(x_1), y_2 \in \Phi(x_2)} (t \text{dist}(y_1, C) + (1-t) \text{dist}(y_2, C)) = t \sup_{y_1 \in \Phi(x_1)} \text{dist}(y_1, C) + (1-t) \sup_{y_2 \in \Phi(x_2)} \text{dist}(y_2, C) = t \varphi_\Phi(x_1) + (1-t) \varphi_\Phi(x_2).
\]

(iii) This assertion is a straightforward consequence of the above assertions (i) and (ii). \( \square \)

A quantitative behaviour, which can be regarded a counterpart of the metric decrease property for set-valued mapping taking values in a partially ordered Banach space, is captured by the next definition.

**Definition 5.4** (Metric \( C \)-increase). Given a closed, convex cone \( C \subseteq Y \), a set-valued mapping \( \Phi : X \rightarrow Y \) between Banach spaces is said to be

(i) **metrically \( C \)-increasing** on \( X \) if there exists a constant \( \alpha > 1 \) such that

\[
\forall x \in X, \forall r > 0, \exists u \in B(x, r) : B(\Phi(u), \alpha r) \subseteq B(\Phi(x) + C, r);
\]

the quantity

\[
\text{inc} \, \Phi = \sup \{ \alpha > 1 : \text{inclusion } (5.3) \text{ holds} \}
\]

is called **exact bound of metric \( C \)-increase** of \( \Phi \) on \( X \).

(ii) **metrically \( C \)-increasing** around \( \bar{x} \in \text{dom} \, \Phi \) if there exist \( \delta > 0 \) and \( \alpha > 1 \) such that

\[
\forall x \in B(\bar{x}, \delta), \forall r \in (0, \delta), \exists u \in B(x, r) : B(\Phi(u), \alpha r) \subseteq B(\Phi(x) + C, r);
\]

the quantity

\[
\text{inc} \, \Phi(\bar{x}) = \sup \{ \alpha > 1 : \exists \delta > 0 \text{ such that inclusion } (5.4) \text{ holds} \}
\]

is called **exact bound of metric \( C \)-increase** of \( \Phi \) around \( \bar{x} \).

Let \( \Phi : P \times X \rightarrow Y \) a set-valued mapping, defined on the product of a metric space \( P \) with a Banach space \( X \), and taking values in a Banach space \( Y \), and let \( (\bar{p}, \bar{x}) \in P \times X \). \( \Phi \) is said to be
(iii) metrically $C$-increasing with respect to $x$ around $(\bar{p}, \bar{x})$, uniformly in $p$, if there exist $\delta > 0$ and $\alpha > 1$ such that
\[
(5.5) \quad \forall (p, x) \in B(\bar{p}, \delta) \times B(\bar{x}, \delta), \quad \forall r \in (0, \delta), \quad \exists u \in B(x, r) : \quad B(\Phi(p, u), \alpha r) \subseteq B(\Phi(p, x) + C, r);
\]
the quantity
\[
\text{inc } \Phi_x(\bar{p}, \bar{x}) = \sup \{ \alpha > 1 : \text{ inclusion (5.5) holds} \}
\]
is called exact uniform bound of metric $C$-increase of $\Phi$ near $(\bar{p}, \bar{x})$.

The above properties have been already used in connection with the study of error bounds for set-valued inclusions in \[22\], where several examples of the occurrence of the metric $C$-increase property in global and local form can be found.

**Remark 5.5.** In the proof of the next proposition, the following facts concerning the properties of the excess and the support function will be employed. Let $S \subseteq Y$ be a nonempty subset, let $C \subseteq Y$ be a closed, convex cone, and let $r > 0$. Then, the following equalities hold:

(i) \[ \text{exc } (S + C, C) = \text{exc } (S, C) \quad \text{(see [22, Remark 2.1])}; \]

(ii) if \[ \text{exc } (S, C) > 0, \] then \[ \text{exc } (B(S, r), C) = \text{exc } (S, C) + r \quad \text{(see [22, Lemma 2.2]).} \]

Let $S \subseteq X$ be a closed, convex set, and let \( \zeta(x, S) : X \to R \cup \{ \pm \infty \} \) denote its support function, i.e. \( \zeta(x, S) = \sup_{x^* \in X^*} \langle x^*, x \rangle \), where \( \langle \cdot, \cdot \rangle \) denotes the duality pairing the space $X$ and its dual $X^*$. Then, \( 0^* \in S \) iff \[ [\zeta(\cdot, S) \geq 0] = X \] and, more precisely, the following distance estimate holds
\[
(5.6) \quad \text{dist } (0^*, S) \geq - \inf_{u \in B} \zeta(u, S)
\]
(see, for instance, \[28\] Remark 2.1).

The next proposition explains the role of the property introduced in Definition 5.4 within the present approach. Roughly speaking, it provides a method for measuring the violation of the set-valued inclusion $\Phi(x) \subseteq C$ near a solution $\bar{x} \in X^+(C)$. This is done by tools of convex analysis both in the primal space (via the directional derivative of $\varphi_\Phi$) and in the dual space (via the subdifferential of $\varphi_\Phi$). Recall that, given a convex function $\psi : X \to R \cup \{ \pm \}$ and a point $x \in \psi^{-1}(R)$ the value
\[
\psi'(x; v) = \lim_{t \to 0^+} \frac{\psi(x + tv) - \psi(x)}{t},
\]
is called directional derivative of $\psi$ at $x$, in the direction $v \in X$.

**Proposition 5.6.** Let $\Phi : X \rightrightarrows Y$ be a set-valued mapping between Banach spaces, let $C \subseteq Y$ a closed, convex cone and let $\bar{x} \in X$ such that $\Phi(\bar{x}) \subseteq C$. Suppose that:

(i) $\Phi$ is l.s.c., concave and bounded-valued away from $C$ on $X$;

(ii) $\Phi$ is metrically $C$-increasing around $\bar{x}$, with exact bound $\text{inc } \Phi(\bar{x})$.

Then, there exists $\eta > 0$ such that
\[
(5.7) \quad \inf_{u \in B} \varphi_\Phi'(x; u) \leq 1 - \text{inc } \Phi(\bar{x}), \quad \forall x \in B(\bar{x}, \eta) \cap [\varphi_\Phi > 0],
\]
and hence
\[
(5.8) \quad \text{dist } (0^*, \partial \varphi_\Phi(x)) \geq \text{inc } \Phi(\bar{x}) - 1 > 0, \quad \forall x \in B(\bar{x}, \eta) \cap [\varphi_\Phi > 0].
\]

If hypothesis (ii) is replaced with

(ii) $\Phi$ is metrically $C$-increasing on $X$, with exact bound $\text{inc } \Phi$,

then, one has
\[
(5.9) \quad \inf_{u \in B} \varphi_\Phi'(x; u) \leq 1 - \text{inc } \Phi, \quad \forall x \in [\varphi_\Phi > 0],
\]
and hence
\[
(5.10) \quad \text{dist } (0^*, \partial \varphi_\Phi(x)) \geq \text{inc } \Phi - 1 > 0, \quad \forall x \in [\varphi_\Phi > 0].
\]
Proof. First of all observe that, on account of Lemma 2.4(i), Lemma 5.3(ii), and Remark 2.5 by hypothesis (i) the function \( \varphi : X \to \mathbb{R} \) is l.s.c., convex and \( \varphi^1(\mathbb{R}) = X \).

Fix an arbitrary \( \alpha \in (1, \text{inc } \Phi(\bar{x})) \) and let \( \delta > 0 \) be as in Definition 5.4(ii). Take an arbitrary \( x_0 \in B(\bar{x}, \delta) \cap [\varphi > 0] \). Since it is \( \varphi(x_0) > \varphi(\bar{x}) = 0 \), the point \( x_0 \) can not be a (global) minimizer of \( \varphi \). Consequently, as the inclusion \( 0^* \in \partial \varphi(x_0) \) characterizes the minimality for a convex function, it must be \( 0^* \not\in \partial \varphi(x_0) \). Since function \( \varphi \) is l.s.c. on \( X \), the superlevel set \([\varphi > 0]\) turns out to be open, so there exists \( \delta_0 > 0 \) such that \( B(x_0, \delta_0) \subseteq [\varphi > 0] \), what means that

\[
\Phi(x) \not\subseteq C, \quad \forall x \in B(x_0, \delta_0).
\]

Now, according to hypothesis (ii), for every \( t \in (0, \delta_0) \) there exists \( u_t \in B \) such that

\[
B(\Phi(x_0 + tu), at) \subseteq B(\Phi(x_0) + C, t),
\]

while \( \Phi(x_0 + tu) \not\subseteq C \). By taking into account the equalities in Remark 5.5(i) and (ii), one obtains

\[
(5.11) \quad \text{exc}(B(\Phi(x_0 + tu), at), C) \leq \text{exc}(B(\Phi(x_0) + C, t), C) = \text{exc}(\Phi(x_0) + C, t) + t = \text{exc}(\Phi(x_0) + C, t + \varphi(x_0)) + t.
\]

On the other hand, one has

\[
(5.12) \quad \text{exc}(B(\Phi(x_0 + tu), at), C) = \text{exc}(\Phi(x_0 + tu), C) + at = \varphi(x_0 + tu) + at.
\]

From equality (5.12) and the relations in (5.11), one deduces

\[
\inf_{u \in B} \frac{\varphi(x_0 + tu) - \varphi(x_0)}{t} \leq \frac{\varphi(x_0 + tu_t) - \varphi(x_0)}{t} \leq 1 - \alpha, \quad \forall t \in (0, \delta_0).
\]

Therefore, it results in

\[
\inf_{u \in B} \varphi'(x_0; u) = \inf_{u \in B} \inf_{t \in (0, \delta_0)} \frac{\varphi(x_0 + tu) - \varphi(x_0)}{t} = \inf_{t \in (0, \delta_0)} \inf_{u \in B} \frac{\varphi(x_0 + tu) - \varphi(x_0)}{t} \leq 1 - \alpha.
\]

Thus, by arbitrariness of \( \alpha \in (1, \text{inc } \Phi) \) and \( x_0 \in B(\bar{x}, \delta) \cap [\varphi > 0] \), it suffices to set \( \eta = \delta \) to obtain inequality (5.7). The estimate in (5.8) can be established by exploiting the inequality (5.6) in Remark 5.6 and by recalling the Moreau-Rockafellar representation formula for the directional derivative of a l.s.c. convex function

\[
\varphi'(x; u) = \varsigma(u, \partial \varphi(x)), \quad \forall u \in X,
\]

which is valid for every \( x \in \text{core } (\text{dom } \varphi) = X \) (see, for instance, [3, Theorem 4.2.7]). Here core \( S \) denotes the core of the set \( S \).

The second part of the thesis, upon hypothesis (ii'), can be proved in a similar manner, with plane adaptations. \( \Box \)

Let us come back now to the context of parameterized set-valued inclusions (SVI\( X \)). It will be assume henceforth that for any \( p \in P \) near \( \bar{p} \), the set-valued mapping \( x \mapsto F(p, x) \) is concave. Notice that, upon such an assumption, an appreciable consequence of equality (5.1) is that \( S : P \ni \bar{X} \) is convex-valued, in the light of Lemma 5.3(ii). Moreover, some estimates of the constants in (5.1) can be obtained via exact bounds of metric \( C \)-increase, as stated below.

**Theorem 5.7.** Let \( F : P \times \bar{X} \ni Y \) be a set-valued mapping, defined on the product of a metric space \( P \) with a Banach space \( \bar{X} \), and taking values in a Banach space \( Y \). Let \( C \subseteq \bar{Y} \) a closed, convex cone, let \( \bar{p} \in P \) and let \( \bar{x} \in S(\bar{p}) \). Suppose that each set-valued mapping \( F(\bar{p}, \cdot) : \bar{X} \ni \bar{Y} \) is l.s.c., concave and bounded-valued away from \( C \) on \( \bar{X} \), for every \( p \in B(\bar{p}, \delta) \), for some \( \delta > 0 \).

(i) If \( F \) is metrically \( C \)-increasing with respect to \( x \) around \( (\bar{p}, \bar{x}) \), uniformly in \( p \) with exact uniform bound \( \text{inc } F_x(\bar{p}, \bar{x}) \), then it holds

\[
[\nabla_x \varphi F]^\top(\bar{p}, \bar{x}) \geq \text{inc } F_x(\bar{p}, \bar{x}) - 1 > 0.
\]

(ii) If \( F(\bar{p}, \cdot) \) is metrically \( C \)-increasing around \( \bar{x} \), with exact bound \( \text{inc } F(\bar{p}, \cdot)(\bar{x}) \), then

\[
[\nabla \varphi F(\bar{p}, \cdot)]^\top(\bar{x}) \geq \text{inc } F(\bar{p}, \cdot)(\bar{x}) - 1 > 0.
\]
(iii) If $F(\bar{p}, \cdot)$ is metrically $C$-increasing on $\mathbb{X}$, with exact bound $\text{inc} F(\bar{p}, \cdot)$, then

$$\tau_{\bar{p}} \geq \text{inc} F(\bar{p}, \cdot) - 1 > 0.$$ 

**Proof.** (i) Under the current assumptions, it is possible to apply Proposition 5.6 to each function $F(p, \cdot) : \mathbb{X} \ni \mathbb{Y}$, with $p \in B(\bar{p}, \delta)$. As a consequence, there exists $\eta > 0$ such that

$$\text{dist} (\mathbf{0}^*, \partial \varphi F(p, \cdot)(x)) \geq \text{inc} F_x(\bar{p}, \bar{x}) - 1, \quad \forall x \in B(\bar{x}, \eta) \cap [\varphi F(p, \cdot) > 0].$$

Without loss of generality, one can assume $\eta < \delta$. It is to be noticed that the value of $\eta$ is the same for each $p \in B(\bar{p}, \delta)$, by virtue of the uniform version of the metric $C$-increase property postulated in hypothesis (i). Thus, in the light of Example 2.6(ii), it results in

$$|\nabla \varphi F(p, \cdot)|(\bar{x}) = \text{dist} (\mathbf{0}^*, \partial \varphi F(p, \cdot)(x)) \geq \text{inc} F_x(\bar{p}, \bar{x}) - 1, \quad \forall (p, x) \in B(\bar{p}, \eta) \times B(\bar{x}, \eta) : \varphi F(p, x) > 0.$$ 

By recalling the definition in (4.2), one immediately obtains

$$\overline{\nabla \varphi F}^{-} (\bar{p}, \bar{x}) = \lim_{\epsilon \to 0^+} \inf_{\epsilon} |\nabla \varphi F(p, \cdot)|(x) : (p, x) \in B(\bar{p}, \epsilon) \times B(\bar{x}, \epsilon),$$

$$\varphi F(\bar{p}, \bar{x}) < \varphi F(p, x) < \varphi F(\bar{p}, \bar{x}) + \epsilon \}
\geq \inf \{ \text{dist} (\mathbf{0}^*, \partial \varphi F(p, \cdot)(x)) : (p, x) \in B(\bar{p}, \eta) \times B(\bar{x}, \eta), \varphi F(p, x) > 0 \}$$

$$\geq \text{inc} F_x(\bar{p}, \bar{x}) - 1 > 0.$$ 

In the case of assertions (ii) and (iii), it suffices to apply Proposition 5.6 with $\Phi = F(\bar{p}, \cdot)$ and to recall that

$$|\nabla \varphi F(\bar{p}, \cdot)|(x) = \text{dist} (\mathbf{0}^*, \partial \varphi F(\bar{p}, \cdot))(x).$$

This completes the proof. 

\[ \square \]
