INDECOMPOSABLE INJECTIVE MODULES OF FINITE MALCEV RANK OVER LOCAL COMMUTATIVE RINGS

FRANÇOIS COUCHOT

ABSTRACT. It is proven that each indecomposable injective module over a valuation domain $R$ is polyserial if and only if each maximal immediate extension $\hat{R}$ of $R$ is of finite rank over the completion $\hat{R}$ of $R$ in the $R$-topology. In this case, for each indecomposable injective module $E$, the following invariants are finite and equal: its Malcev rank, its Fleischer rank and its dual Goldie dimension. Similar results are obtained for chain rings satisfying some additional properties. It is also shown that each indecomposable injective module over one Krull-dimensional local Noetherian rings has finite Malcev rank. The preservation of Goldie dimension finiteness by localization is investigated too.

INTRODUCTION AND PRELIMINARIES

In this paper all rings are associative and commutative with unity and all modules are unital. First we give some definitions.

Definition 0.1. An $R$-module $M$ is said to be uniserial if its set of submodules is totally ordered by inclusion and $R$ is a chain ring if it is uniserial as $R$-module. A chain domain is a valuation domain. In the sequel, if $R$ is a chain ring, we denote by $P$ its maximal ideal, $N$ its nilradical, $Z$ its set of zero-divisors ($Z$ is a prime ideal) and we put $Q = R_Z$. Recall that a chain ring $R$ is said to be Archimedean if $P$ is the sole non-zero prime ideal.

A module $M$ is said to be finitely cogenerated if its injective hull is a finite direct sum of injective hulls of simple modules. The f.c. topology on a module $M$ is the linear topology defined by taking as a basis of neighbourhoods of zero all submodules $G$ for which $M/G$ is finitely cogenerated (see [17]). This topology is always Hausdorff. We denote by $\hat{M}$ the completion of $M$ in its f.c. topology. When $R$ is a chain ring which is not a finitely cogenerated $R$-module, the f.c. topology on $R$ coincides with the $R$-topology which is defined by taking as a basis of neighbourhoods of zero all non-zero principal ideals. A chain ring $R$ is said to be (almost) maximal if $R/A$ is complete in its f.c. topology for any (non-zero) proper ideal $A$.

In 1959, Matlis proved that a valuation domain $R$ is almost maximal if and only if $Q/R$ is injective, and in this case, for each proper ideal $A$ of $R$, $E(R/A) \cong Q/A$, see [15, Theorem 4]. Since $Q$ is clearly uniserial and $Q/R \cong Q/rR$ for each non-zero element $r \in P$, we can also say that $R$ is almost maximal if and only if $E(R/rR)$

Key words and phrases. chain ring, valuation domain, polyserial module, indecomposable injective module, Goldie dimension.

\textsuperscript{1}we prefer “chain ring” to “valuation ring” to avoid confusion with “Manis valuation ring”.

hal-00617500, version 1 - 29 Aug 2011
is uniserial, if and only if each indecomposable injective module is uniserial. This result was extended to any chain ring in 1971 by Gill, see [11, Theorem]: a chain ring $R$ is almost maximal if and only if $E(R/P)$ is uniserial, if and only if each indecomposable injective module is uniserial. By using [2, Proposition 14], if $R$ is a chain ring, it is easy to check that $E(R/rR)$ is uniserial if and only if so is $E(R/P)$. Let us observe that any indecomposable injective module is uniserial if and only if each finitely generated uniform module is cyclic.

**Definition 0.2.** If $M$ is a finitely generated module we denote by gen $M$ its minimal number of generators. If $M$ is a module over a valuation domain $R$ the **Fleischer rank** of $M$, denoted by $Fr(M)$, is defined to be the minimum rank of torsion-free modules having $M$ as an epimorphic image.

In the book “Modules over valuation domains” by Fuchs and Salce [9, Proposition IX.3.1](1985), it is proven that gen $M \leq Fr(E(R/P))$ for each finitely generated uniform module $M$ over a valuation domain $R$. However, it remains to give a characterization of valuation domains $R$ for which $Fr(E(R/P))$ is finite.

In 2005 [3, Proposition 2], if $R$ is an Archimedean chain ring, the author proved that there exists an integer $p > 0$ such that gen $M \leq p$ for each finitely generated uniform module $M$ if and only if $R$ is almost maximal, (i.e $p = 1$).

**Definition 0.3.** An exact sequence $0 \rightarrow F \rightarrow E \rightarrow G \rightarrow 0$ is **pure** if it remains exact when tensoring it with any $R$-module. In this case we say that $F$ is a pure submodule of $E$. We say that a module $M$ is **polyserial** if it has a pure-composition series

$$0 = M_0 \subset M_1 \subset \cdots \subset M_n = M,$$

i.e. $M_k$ is a pure submodule of $M$ and $M_k/M_{k-1}$ is a uniserial module for each $k = 1, \ldots, n$.

The **Malcev rank** of a module $M$ is defined as the cardinal number

$$Mr(M) = \sup\{\text{gen } X \mid X \text{ finitely generated submodule of } M\}.$$

For each module $M$ over a valuation domain we have $Mr(M) \leq Fr(M)$.

An $R$-module $F$ is **pure-injective** if for every pure exact sequence

$$0 \rightarrow A \rightarrow B \rightarrow C \rightarrow 0$$

of $R$-modules, the following sequence

$$0 \rightarrow \text{Hom}_R(C, F) \rightarrow \text{Hom}_R(B, F) \rightarrow \text{Hom}_R(A, F) \rightarrow 0$$

is exact. An $R$-module $B$ is a **pure-essential extension** of a submodule $A$ if $A$ is a pure submodule of $B$ and, if for each submodule $K$ of $B$, either $K \cap A \neq 0$ or $(A + K)/K$ is not a pure submodule of $B/K$. We say that $B$ is a **pure-injective hull** of $A$ if $B$ is pure-injective and a pure-essential extension of $A$. By [19] or [10, chapter XIII] each $R$-module $M$ has a pure-injective hull and any two pure-injective hulls of $M$ are isomorphic. In the sequel, for each $R$-module $M$, $\hat{M}$ is its pure-injective hull.
In this paper we give a characterization of two classes of chain rings. The first is the class of chain rings $R$ for which each indecomposable injective module is polyserial (Theorem 2.3). These rings are exactly the chain rings $R$ which satisfy the following two conditions:

1. $\text{Mr}_R\hat{R} < \infty$;
2. each indecomposable injective module contains a pure uniserial submodule\(^2\).

The first condition is equivalent to the following: there is a non-zero prime ideal $L$ such that $R_L$ is almost maximal and the valuation domain $R/L$ has a maximal immediate extension of finite rank which is equal to $\text{Mr}_R\hat{R}$. These rings are almost maximal by stages, i.e. there exists a finite descending chain of prime ideals $(L_i)_{0 \leq i \leq n}$, with $L_0 = P$ such that $(R/L_{i+1})_{L_i}$ is almost maximal for $i = 0, \ldots, n-1$ and $\hat{R}_{L_n}$ is maximal. Moreover, for each finitely generated uniform module $M$, $\text{gen} M \leq \text{Mr}_R\hat{R}$, and for each indecomposable injective module $E$, $\text{Mr}_RE \leq \text{Mr}_R\hat{R}$, the equalities hold for some $M$ and $E$. If $R$ is not a domain then $\text{Mr}_R\hat{R} < \infty$. A description of such chain rings $R$ is given, and this description is similar to the one of valuation domains with a maximal immediate extension of finite rank ([7, Theorem 10 and Proposition 11]).

The second class is the one of chain rings $R$ for which each localization of any $R$-module of finite Goldie dimension has finite Goldie dimension too. These rings are exactly the chain rings $R$ for which $R/L$ has a maximal immediate extension of finite rank for each non-zero prime ideal $L$. So, the first class is contained but strictly in the second one, and some examples are given.

It is also shown that the completion $\hat{R}$ of any chain ring $R$ in its f.c. topology is Gaussian, and $\hat{R}$ is a chain ring if and only if $R$ is either complete or a domain.

For each one Krull-dimensional local Noetherian ring $R$ it is proven that there exists a positive integer $m$ such that $\text{Mr} E \leq m$ for every indecomposable injective $R$-module $E$. Moreover, for each integer $m > 1$ we give an example of a one Krull-dimensional local Noetherian domain $D$ satisfying $\text{gen} M \leq m$ for each finitely generated uniform $D$-module $M$. However, if $R$ is a chain ring with a such upper bound $m$ then $m$ is a prime power.

**Definition 0.4.** Let $M$ be a non-zero module over a ring $R$. We set:

$$M_2 = \{ s \in R \mid \exists 0 \neq x \in M \text{ such that } sx = 0 \} \quad \text{and} \quad M^2 = \{ s \in R \mid sM \subset M \}.$$  

Then $R \setminus M_2$ and $R \setminus M^2$ are multiplicative subsets of $R$.

If $M$ is a module over a chain ring $R$ then $M_2$ and $M^2$ are prime ideals and they are called the **bottom** and the **top prime ideal**, respectively, associated with $M$.

We say that an $R$-module $E$ is **FP-injective** if $\text{Ext}_R^1(F, E) = 0$, for every finitely presented $R$-module $F$. A ring $R$ is called **self FP-injective** if it is FP-injective as $R$-module. Recall that a module $E$ is FP-injective if and only if it is a pure submodule of every overmodule.

If $L$ is a prime ideal of a chain ring $R$, as in [8], we define the **total defect** at $L$, $d_R(L)$, the **completion defect** at $L$, $c_R(L)$, as the rank of the torsion-free $R/L$-module $\hat{R}/L$ and the rank of the torsion-free $R/L$-module $\hat{R}/L$, respectively.

---

\(^2\)This condition holds for each valuation domain and other classes of chain rings but we don’t know if it is verified by any chain ring.
1. Relations between $\hat{R}$ and $\tilde{R}$

Given a ring $R$, an $R$-module $M$ and $x \in M$, the content ideal $c(x)$ of $x$ in $M$, is the intersection of all ideals $A$ for which $x \in AM$.

When $R$ is a chain ring, the breadth ideal $B(x)$ of an element $x$ in $\hat{R}$ is defined by $B(x) = c(x + R)$. So, $B(x) = 0$ if $x \in R$. Since $\hat{R} = R + P\hat{R}$ by [5, Proposition 1] then $B(x) = \{r \in R \mid x \notin R + r\hat{R}\}$ if $x \in \hat{R} \setminus R$.

The following lemma will be often used in the sequel.

**Lemma 1.1.** [5, Proposition 20 and Lemma 21] Let $R$ be a chain ring. Then:

1. $R/A$ is not complete in its f.c. topology if and only if there exists $x \in \hat{R} \setminus R$ such that $A = B(x)$;
2. if $x \in \hat{R}$ and $x = r + ay$ for some $r, a \in R$ and $y \in \tilde{R}$, then $B(y) = (B(x) : a)$.

**Proposition 1.2.** Let $R$ be a chain ring. Then:

1. $\hat{R}$ has a structure of $\tilde{R}$-module which extends its structure of $R$-module;
2. $\hat{R}$ is isomorphic to the submodule of $\tilde{R}$ whose elements $x$ satisfy $B(x) = 0$;
3. for each non-zero prime ideal $L$ of $R$ there exists a prime ideal $L'$ of $\hat{R}$ such that $\hat{R}/L' \cong R/L$ and $L'/\hat{R} = LR$;
4. $\hat{R}/R$ is a $Q/Z$-vector space.

**Proof.** (1). If $R$ is finitely cogenerated then $\hat{R} = R$. If not we have $\bigcap_{r \in R \setminus \{0\}} rP = 0$. Let $a \in \hat{R}$ and $x \in \hat{R}$. Let $(a + rP)_{r \in R \setminus \{0\}}$ be the family of cosets of $R$ which defines $a$. If $r \in sR$ then $(a_r - a_s) \in sP$, and it follows that $\{a_r - a_s \mid r \in sP\}$ by [5, Proposition 4] the family $F = (a_r + rP\hat{R})_{r \in R \setminus \{0\}}$ has a non-empty intersection. By [5, Lemma 19] $\bigcap_{r \in R \setminus \{0\}} rP\hat{R} = 0$, whence the intersection of the family $F$ contains $0$. Now it is easy to complete the proof.

(2). We do as in (1) by taking $x = 1$. So, for each $a \in \hat{R}$ corresponds a unique element $y \in \hat{R}$ such that $B(y) = 0$. It is easy to check that we get a monomorphism from $\hat{R}$ into $\tilde{R}$.

(3). We may assume that $R$ is not finitely cogenerated. Since each non-zero ideal is open in the f.c. topology of $R$, we have $\hat{R} \cong \varprojlim_{\mathcal{I}} R/A$, where $\mathcal{I}$ is the set of non-zero ideals of $R$. So, there exists a surjection $\phi : \hat{R} \twoheadrightarrow R/L$. We put $L' = \ker \phi$. Let $0 \neq a \in L'$ and $0 \neq x \in \hat{R}$, and let $\{a_r + rP\}_{r \in R \setminus \{0\}}$ be the family of cosets of $R$ which defines $a$. There exists $r \in L$ such that $a_r \in L \setminus rR$. We set $a' = a_r$. Let $s \in rR$. Since $(a_s - a') \in rR \subset a' R$ then $a_s = a'u_s$ for some $u_s \in R$. If $t \in sR$ then $a'(u_s - u_t) \in sR$, whence $(u_s - u_t) \in (sR : a')$. The family $(u_s x + (sR : a')\hat{R})_{s \in R \setminus \{0\}}$ has a non-empty intersection. Let $y$ an element of this intersection. Since $(a'y - a_s x) \in s\hat{R}$ for each $s \in a' R \setminus \{0\}$, it follows that $(a'y - ax) \in \cap_{s \in a' R \setminus \{0\}} s\hat{R} = 0$. Hence $ax = a'y$.

(4). Let $x \in \hat{R}$ and $s \in R \setminus S$. Suppose that $sx = 0$. By [5, Proposition 1] $x = r + rpy$ for some $r \in R, p \in P$ and $y \in \hat{R}$. Since $R$ is a pure submodule of $\hat{R}$, there exists $t \in R$ such that $r = 0$. We successively deduce that $sr = 0, r = 0$ and $x = 0$. Now, suppose that $sx \in R$. Then there exists $t \in R$ such that $sx = st$, whence $x = t$. So, the multiplication by $s$ in $\hat{R}/R$ is injective. Since $B(x) = 0, x = a + sy$ for some $a \in R$ and $y \in \hat{R}$. But $B(y) = (0 : s) = 0, s \in R$. But
We conclude that the multiplication by \( s \) in \( \tilde{R}/R \) is bijective. Now let \( a \in Z \). Then \((0 : a)\) contains a non-zero element \( b \). From \( B(x) = 0 \) we deduce that \( x = r + bz \) for some \( r \in R \) and \( z \in \tilde{R} \). It follows that \( ax \in R \). The proof is complete. \( \square \)

A local ring \( R \) is called Gaussian\(^3\) if, for any ideal \( A \) generated by two elements \( a, b \) in \( R \), the following two properties hold:

1. \( A^2 \) is generated by \( a^2 \) or \( b^2 \);
2. if \( A^2 \) is generated by \( a^2 \) and \( ab = 0 \), then \( b^2 = 0 \).

**Theorem 1.3.** Let \( R \) be a chain ring. The following assertions hold:

1. \( \tilde{R} \) is a local Gaussian ring;
2. the following conditions are equivalent:
   a. \( \tilde{R} \) is a chain ring;
   b. \( R \) is either complete or a domain;
   c. \( \tilde{R} \) is a pure \( R \)-submodule of \( \tilde{R} \);
   d. \( \tilde{R} \) is a flat \( R \)-module.

**Proof.** (1). \( \tilde{R} \) is local because it is the inverse limit of a system of local rings with local connecting homomorphisms.

We may assume that \( R \) is not finitely cogenerated. Let \( a \) and \( b \) be two elements of \( R \). By [5, Proposition 1] there exist \( a', b' \in \tilde{R} \) and \( x, y \in 1 + PR \) such that \( a = a'x \) and \( b = b'y \). We may assume that \( b' = ra' \) for some \( r \in R \). First suppose that \( a' \notin Z \). By Lemma 1.1(2) \( B(x) = 0 : a' = 0 \), whence \( x \in \tilde{R} \), and \( B(y) = 0 : ra' = (0 : r) \). It follows that \( x \) is a unit of \( \tilde{R} \), \( B(ry) = 0 \), so \( ry \in \tilde{R} \) and \( b = x^{-1}(ry)a' \). If \( ab = 0 \), it follows that \((ry)a^2 = 0 \), whence \( b^2 = 0 \). Now, assume that \( a' \in Z \). Let \( 0 \neq t \in (0 : a') \cap b'P \). Then \( a = c + tz \) and \( b = d + tw \) for some \( c, d \in R \) and \( z, w \in \tilde{R} \). So, we have \( a = a'(1 + px') = c + a't'z \) where \( p, t' \in P \) and \( x' \in \tilde{R} \). From \( R \) pure submodule of \( \tilde{R} \) we deduce that \( c = ua' \) for some unit \( u \in R \). In the same way \( d = vb' \) for some unit \( v \in R \). It follows that \( a^2 = u^2a^2 \), \( ab = uva^2 = u^{-1}vra^2 \) and \( b^2 = v^2r^2a^2 = u^{-2}r^2v^2a^2 \). If \( ab = 0 \), then \( ra^2 = 0 \), whence \( b^2 = 0 \).

2. It is well known that (b) implies the other three conditions.

Assume that \( R \) is neither complete nor a domain. Let \( 0 \neq a \in \tilde{R} \) and \( 0 \neq r \in Z \). Since \( B(a) = 0 \) then \( a = s + xr \) for some \( s \in R \) and \( x \in \tilde{R} \). It follows that \( rx \in \tilde{R} \). If \( rx = ry \) then \( B(y) = 0 : r \neq 0 \) by Lemma 1.1(2). So, \( rx \notin r\tilde{R} \) and \( \tilde{R} \) is not a pure submodule of \( \tilde{R} \). Now suppose that \( r \in \tilde{R} rx \), whence \( r = bx \) for some \( b \in \tilde{R} \). We have \( B(bx) = 0 : r \), so \( bx \notin \tilde{R} + (0 : r)\tilde{R} \). From \( r(bx - 1) = 0 \) and the flatness of \( \tilde{R} \) we deduce that \( bx - 1 = sy \) for some \( s \in (0 : r) \) and \( y \in \tilde{R} \). We get a contradiction. So, \( \tilde{R} \) is not a chain ring. Hence, \( (a) \Rightarrow (b) \) and \( (c) \Rightarrow (b) \).

(\(d\)) \(\Rightarrow (b) \). Since \( R \) is a pure submodule of \( \tilde{R} \), \( \tilde{R}/R \) is flat. By Proposition 1.2 it is a semisimple \( Q \)-module. It follows that either \( \tilde{R}/R = 0 \) or \( Q \) is a field. We conclude that the condition (b) holds. \( \square \)

**Proposition 1.4.** Let \( R \) be a chain ring. Assume \((0 : a) = Z \) for some \( a \in R \). Then \( Mr \tilde{R} = cR(Z) \).

---

\(^3\)This definition is equivalent to the usual one when \( R \) is local, see [16].
Proof. Let \( R' = R/Z \). We shall prove that \( \tilde{R}'/R' \) and \( \tilde{R}/R \) are isomorphic. Since 
\( \tilde{R}' \subseteq \hat{R}' \cong \hat{R}/Z \), \( \tilde{R}'/R' \) is isomorphic to the submodule of \( \hat{R}'/(R + Z \hat{R}) \) whose 
elements \( x + (R + Z \hat{R}) \) satisfy \( B(x) = Z \) (it is easy to check that \( B(x') = B(x) \)
if \( x' \in x + (R + Z \hat{R}) \) and \( x \neq R + Z \hat{R} \). On the other hand, \( \tilde{R} \subseteq R + a \hat{R} \), 
whence \( \tilde{R}/R \) is isomorphic to a submodule of \( (R + a \hat{R})/R \). For each \( x \in \tilde{R} \) we put 
\( \phi(x + (R + Z \hat{R})) = ax + R \). It is easy to check that \( \phi \) is a well defined epimorphism 
from \( \hat{R}'/(R + Z \hat{R}) \) into \( (R + a \hat{R})/R \). If \( ax \in R \), then \( ax = ad \) for some \( d \in R \) 
because \( R \) is a pure submodule of \( \tilde{R} \). From \( a(x - d) = 0 \) and the flatness of \( \tilde{R} \) we 
deduce that \( (x - d) \in Z \hat{R} \). So, \( \phi \) is an isomorphism. By Lemma 1.1(2) \( B(x) = Z \) if 
and only if \( B(ax) = 0 \). Consequently, the restriction of \( \phi \) to \( \tilde{R}'/R' \) is an isomorphism 
onto \( \tilde{R}/R \).

2. Polyserial injective modules

The following proposition is a slight generalization of [3, Proposition 2].

**Proposition 2.1.** Let \( R \) be an Archimedean chain ring. Assume that there exists 
a non-zero injective module \( E \) such that \( E_j = P \) and Mr \( E < \infty \). Then \( R \) is almost 
maximal.

**Proof.** It is an immediate consequence of [3, Proposition 2] and its proof. The 
existence of an injective module \( E \) with Mr \( E < \infty \) (\( \nu(E) < \infty \)) is used to show 
that \( R \) is almost maximal.

We say that a module \( M \) is **singly projective** if, for any cyclic submodule \( G \), 
the inclusion map \( G \to M \) factors through a free module \( F \). The following theorem 
generalizes [7, Theorem 10 and Proposition 11]

**Theorem 2.2.** Let \( R \) be a chain ring. The following conditions are equivalent:

(1) \( \hat{R} \) is a polyserial module;

(2) Mr \( \hat{R} < \infty \).

In this case there exists a finite family of prime ideals

\[ P = L_0 \supset L_1 \supset \cdots \supset L_{m-1} \supset L_m \supset N \]

such that \( (R/L_{k+1})_{L_k} \) is almost maximal, \( \forall k, 0 \leq k \leq m-1 \), and \( R_{L_m} \) is maximal.

Moreover,

(a) \( \hat{R} \) has a pure-composition series \( S \)

\[ 0 = F_0 \subset R = F_1 \subset \cdots \subset F_m \subset F_{m+1} = \hat{R} \]

where \( F_{j+1}/F_j \) is a free \( R_{L_j} \)-module of finite rank, \( \forall j, 0 \leq j \leq m; \)

(b) Mr \( \hat{R} = d_R(L_m) = \prod_{k=1}^{m} c_R(L_k); \)

(c) \( \hat{R} \) is polyserial and Mr \( \hat{R} = c_R(Z) \).

**Proof.** By [10, Lemma XII.1.4] (1) \( \Rightarrow \) (2).

(2) \( \Rightarrow \) (1). When \( R \) is a valuation domain each torsion-free module of finite rank 
is polyserial. So, we may assume that \( R \) is not a domain.

First we will show that \( R_N \) is maximal. Since each non-unit of \( R_N \) is a zero-
divisor, \( R_N \) is self FP-injective. From [5, Propositions 1] it is easy to deduce that 
\( \hat{R} \) is singly projective. By [6, Proposition 6] so that is \( (\hat{R})_N \) over \( R_N \). By [6,
Propositions 3] \((\hat{R})_N\) is FP-injective and by [5, Proposition 5] it is pure-injective, whence it is an injective module. It is easy to check that \(\text{Mr } (\hat{R})_N < \infty\). By proposition 2.1 and [11, Proposition 1] we conclude that \(R_N\) is maximal.

Now we shall build the pure composition series \(S\). By [5, Theorem 2.4.(2)] \(\hat{R}/N = \hat{R}/N\hat{R}\). Hence rank \(\hat{R}/N = \text{Mr } \hat{R}/N < \infty\). We apply [7, Theorem 10 and Proposition 11] to \(R/N\). There exists a finite family of prime ideals

\[
P = L_0 \supset L_1 \supset \cdots \supset L_{m-1} \supset L_m = N
\]

such that \((R/L_{k+1})_{L_k}\) is almost maximal, \(\forall k, 0 \leq k \leq m - 1\), and \((R/N)_{L_m}\) is maximal. Moreover, \(\hat{R}/N\) has a pure-composition series \(S'\)

\[
0 = F'_0 \subset R/N = F'_1 \subset \cdots \subset F'_{m} \subset F'_{m+1} = \hat{R}/N
\]

where \(F'_{j+1}/F'_j\) is a free \((R/N)_{L_j}\)-module of finite rank, \(\forall j, 0 \leq j \leq m\). We proceed by induction on \(j\). Obviously \(F_1 = R\). Suppose that \(F_j\) is built and that \(F_j/NF'_j \cong F'_j\). If \(M = \hat{R}/F_j\) and \(M' = \hat{R}/N\hat{R}/F'_j\), then \(M \cong M'\). So, \(M^j = L_j\), whence \(M\) is a module over \(R_{L_j}\). Moreover, \(M/L_jM\) and \(M'/L_jM'\) have the same rank \(p_j\) over \((R/L_j)_{L_j}\) which is equal to the rank of \(F'_{j+1}/F'_j\) over \((R/N)_{L_j}\). By [6, Proposition 21] \(M\) contains a free \(R_{L_j}\)-module \(G\) of rank \(p_j\) which is a pure submodule of \(M\). Moreover, \(G/NG \cong F'_{j+1}/F'_j\) and \(L_j(M/G) = M/G\). Let \(F_{j+1}\) be the inverse image of \(G\) by the natural map \(\hat{R} \to M\). Hence \(\hat{F}_{j+1}/NF_{j+1} \cong F'_{j+1}\).

Now, let \(H = \hat{R}/F_{m+1}\). Thus \(H\) is flat and \(NH = H\). By [6, Proposition 19] \(H\) is a module over \(R_N\). It is obvious that \((F_{m+1})_N\) is a free module of finite rank over \(R_N\). By [6, Proposition 24] \((F_{m+1})_N\) is a pure-essential submodule of \((\hat{R})_N\). But, since \(R_N\) is maximal \((F_{m+1})_N\) is pure-injective. We deduce that \((F_{m+1})_N = (\hat{R})_N\).

So, \(H = 0\) and \(F_{m+1} = \hat{R}\). The maximality of \((R/N)_{L_m}\) and \(R_N\) implies that \(R_{L_m}\) is maximal if \(L_m \neq N\) (see [5, Theorem 22]).

(b) We apply the last assertion of [7, Theorem 10] to \(R/N\).

(c) We have \(\text{Mr } \hat{R} \leq \text{Mr } \hat{R} < \infty\). So, by Proposition 1.2 \(\hat{R}/R\) is a finite direct sum of modules isomorphic to \(Q/Z\), whence \(\hat{R}\) is polyeserial. If \(A\) is a non-zero proper ideal it is easy to check that \(A^\infty = \{s \in R | A \subset \langle A : s \rangle\}\). So, if we take this definition of top prime ideal for each proper ideal of \(\hat{R}\) we have \(\theta^\infty = Z\). Then \(Z\) is an element of the descending chain of prime ideals \((L_j)_{0 \leq j \leq m}\) if \(R\) is not complete in its f.c. topology. We shall show that there exists \(a \in Z\) such that \(Z = (0 : a)\). By way of contradiction suppose that \(Z\) is faithful. First assume that \(N \subset Z\). If \(t \in Z \setminus N\), then \(0 \neq (0 : t) \subset N\). It follows that \(N \subset Rt \subset (0 : s)\) for some \(0 \neq s \in (0 : t)\). By Lemma 1.1(1) there exists \(x \in \hat{R} \setminus R\) such that \(B(x) = 0\) if \(R\) is not complete. Then \(x = r + sy\) for some \(r \in R\) and \(y \in \hat{R}\) and \(B(y) = (0 : s)\). Consequently, by using again Lemma 1.1(1) we deduce that \(R/(0 : s)\) is not complete. If we consider the valuation domain \(R/N\), from the proof of [7, Proposition 11] we deduce that \((0 : s)/N = bZ/N\) for some \(b \in R\). It follows that \((0 : s) = bZ\), whence \(Z = (0 : bs)\). Now, suppose that \(Z = N\). If \(Z\) is faithful, since \(R_N\) is maximal, as in the proof of [7, Proposition 4] we prove that \(R\) is complete. Hence, if \(\hat{R}\) is not complete, \(Z\) is not faithful. We conclude by Proposition 1.4.

For each module \(M\) we denote by \(A(M)\) its set of annihilator ideals, i.e. an ideal \(A\) belongs to \(A(M)\) if there exists \(0 \neq x \in M\) such that \(A = (0 : x)\).
If $E$ is an indecomposable injective module over a chain ring $R$, then, for any $A, B \in \mathcal{A}(E)$, $A \subset B$ there exists $r \in R$ such that $A = rB$ and $B = (A : r)$. 

Recall that a module $M$ has Goldie dimension $n$ (or $Gd_M = n$) if its injective hull is a direct sum of $n$ indecomposable injective modules.

**Theorem 2.3.** Let $R$ be a chain ring. Consider the following conditions:

1. there exists an indecomposable injective module $E$ such that $E_2 = P$ and $Mr_E < \infty$;
2. there exists a prime ideal $L$ such that $d_R(L) < \infty$ and $R_L$ is almost maximal;
3. $Mr_{\hat{R}} < \infty$ if $R$ is not a domain, and $\hat{R}$ is the extension of a reduced torsion-free module of finite rank with a divisible torsion-free module when $R$ is a domain;
4. the Malcev rank of $\hat{R}$ over $R$ is finite;
5. $Mr_E < \infty$ for each indecomposable injective module $E$;
6. there exists a positive integer $n$ such that $\gen M \leq n$ for each finitely generated uniform $R$-module $M$;
7. there exists a positive integer $n$ such that $\gen M \leq n \times Gd_M$ for each finitely generated $R$-module $M$;
8. each indecomposable injective module is polyserial;
9. there exists an indecomposable injective module $E$ such that $E_2 = P$ which is polyserial.

Then:

- the first seven conditions are equivalent and they are implied by the last two conditions. Moreover, if each indecomposable injective module contains a pure uniserial submodule then the nine conditions are equivalent.
- for each indecomposable injective module $E$, either $Mr_E = 1$ if $J \subseteq L$ or $Mr_E = d_R(L_J) = d_R(L)/d_R(J) = Mr_{R_J}\hat{R}_J$ if $L \subseteq J$, where $J = E_2$ and $L$ is a prime ideal for which $R_L$ is almost maximal. Moreover, $Mr_E$ is the maximum of $\gen_M$ $M$ where $M$ runs over all finitely generated $R$-submodules of uniform $R_J$-modules.

**Proof.** It is obvious that (8) $\Rightarrow$ (9), (6) $\Rightarrow$ (5), (7) $\Rightarrow$ (6) and (5) $\Rightarrow$ (1), and (9) $\Rightarrow$ (1) by [5, Proposition 13].

(1) $\Rightarrow$ (2). By [2, Corollary 28] $E$ is faithful or it is annihilated by a simple ideal if $P = Z$. So, for each non-zero prime ideal $J$ there exists $A \in \mathcal{A}(E)$ such that $A \subset J$. By [2, Lemma 26] $A^2 = E_2 = P$ and by [5, Proposition 1] $\hat{R}/A\hat{R}$ is an essential extension of $R/A$, whence it is isomorphic to a submodule of $E$. We deduce that $d_R(J) = Mr_{\hat{R}/J}\hat{R} \leq Mr_{\hat{R}/A\hat{R}} \leq Mr_E < \infty$. Let $p$ be the maximum of $d_R(J)$ where $J$ runs over all non-zero prime ideals of $R$ and let $L$ be the maximal prime ideal for which $d_R(L) = p$. By Theorem 2.2 $(R/I)_L$ is maximal for each $I \in \mathcal{A}(E)$. We deduce that $R_L$ is almost maximal. Let us observe that $d_R(L) \leq Mr_E$.

(2) $\Rightarrow$ (3) and (4). We do as in the proof of Theorem 2.2: from a pure composition series of $R/L$ we deduce a pure submodule $F$ of $\hat{R}$ with $Mr_F = d_R(L)$ and if $H = \hat{R}/F$, then $LH = H$. If $R$ is not a domain then, as in the proof of Theorem 2.2, we show that $H = 0$, whence $\hat{R}$ is polyserial. It is easy to check that $Mr_{\hat{R}} \hat{R} \leq Mr_{\hat{R}}\hat{R}$. If $R$ is a domain then, for each $a \in L$, $a \neq 0$, $(R/aR)_L$ is maximal. In the
same way we get that \( H = aH \), whence \( H \) is divisible. Since \( \hat{R}/L \hat{R} = R/L \) then \( d_{\hat{R}}(L \hat{R}) = d_R(L) \) and \( (\hat{R})_L \) is maximal. So, \( \hat{R} \) is the extension of a torsion-free \( \hat{R} \)-module \( F \) of rank \( d_R(L) \) with a divisible torsion-free \( \hat{R} \)-module \( H \). Since \( (\hat{R})_L \) is maximal, \( H = 0 \). So, \( \text{Mr}_{\hat{R}} \hat{R} = d_R(L) \).

(4) \( \Rightarrow \) (2). Let \( J \) be a non-zero prime ideal of \( R \). By Proposition 1.2 there exists a prime ideal \( J' \) of \( \hat{R} \) such that \( \hat{R}/J' = R/J \) and \( J' \hat{R} = J \hat{R} \). So, \( \text{Mr}_{\hat{R}} \hat{R}/J \leq \text{Mr}_{\hat{R}} \hat{R} \). Now, we do as in (1) \( \Rightarrow \) (2) to complete the proof.

(3) \( \Rightarrow \) (6). Let \( M \) be a finitely generated uniform module and \( E \) its injective hull. Then \( E \) is indecomposable. Let \( J = E_2 \). Then \( E \) is a module over \( R_J \). If \( J \subseteq L \) then \( E \) is uniserial, so \( \text{Mr} E = 1 \). We may assume that \( L \subseteq J \) and it is easy to check that \( \hat{R}_J \) also satisfies (3). There exists \( A \in \mathcal{A}(E) \) such that \( M \subseteq (0 :E A) \). Let \( E' = (0 :E A) \). By [2, Lemma 26] \( A^j = J \), so, by [5, Theorem 6] \( E' \cong \hat{R}_j/A\hat{R}_j \). If \( R \) is a domain, let \( F \) be a pure reduced torsion-free \( \hat{R}_j \)-submodule of finite rank of \( \hat{R}_j \) such that \( \hat{R}_j/F \) is divisible. Then \( (\hat{R}_j/F) \otimes_{\hat{R}_j} (\hat{R}_j/A \hat{R}_j) = 0 \). So, in this case \( E' \cong (F/AF)_j \) and \( M \leq \text{Mr} E' \leq \text{Mr} \hat{R}_j \). We deduce that \( \text{gen} M \leq \text{rank} F \) or \( \text{gen} M \leq \text{Mr} \hat{R}_j \).

(6) \( \Rightarrow \) (7). Let \( M \) be a finitely generated module and \( E \) its injective hull. By [9, Corollary IX 2.2] \( \text{Gd} M \leq \text{gen} R \). So, \( E = \oplus_{1 \leq j \leq p} E_j \) where \( E_j \) is indecomposable for \( j = 1, \ldots, p \). Let \( \pi_j : E \rightarrow E_j \) the natural projection and \( M_j = \pi_j(M) \). Then \( M \) is isomorphic to a submodule of \( \oplus_{1 \leq j \leq p} M_j \). By (6) \( \text{gen} \oplus_{1 \leq j \leq p} M_j \leq n \times p \). Since each finitely generated ideal is principal, we conclude that \( \text{gen} \, \text{Mr} M \leq \text{gen} \, \text{Mr} \hat{R}_j \).

(3) \( \Rightarrow \) (8). Let \( E \) be an indecomposable injective module. We assume that \( E \) contains a pure uniserial submodule \( U \). If \( J = E_1 \), then \( E \cong \hat{R}_j \otimes_R U \) by [5, corollary 11.4]. If \( R \) is not a domain, then \( \hat{R}_j \) is polyserial by Theorem 2.2. If \( R \) is a domain, we may assume that \( J \neq 0 \). Let \( F \) be a pure reduced torsion-free \( R \)-submodule of finite rank of \( \hat{R}_j \) such that \( \hat{R}_j/F \) is divisible. Then \( (\hat{R}_j/F) \otimes_R U = 0 \), \( E \cong F \otimes_R U \) and we know that \( F \) is polyserial. So, in the two cases, from a pure composition series of \( \hat{R}_j \) or \( F \) with uniserial factors, we deduce a pure composition series of \( E \) with uniserial factors. Hence \( E \) is polyserial.

The second assertion is also proven.

\( \square \)

**Lemma 2.4.** Let \( R \) be a chain ring and let \( E \) be an indecomposable injective module such that \( Z \subseteq E_2 \). Assume that \( E \) contains a pure uniserial submodule. Then each indecomposable injective module \( G \) for which \( Z \subseteq G_2 \) contains a pure uniserial submodule.

**Proof.** After replacing \( R \) by \( R_{E_1} \) we may assume that \( E_2 = P \). First we shall prove that \( E(R/Z) \) contains a pure uniserial submodule. If \( Q \) is coherent, it is a consequence of [2, Corollary 22]. We assume that \( Q \) is not coherent. So, \( Z \) is flat by [2, Theorem 10]. By [4, Theorem 3] \( E_Z \) is injective, \( E_Z \neq 0 \), and it contains a pure uniserial submodule and an injective hull of \( U \). Let \( A \in \mathcal{A}(E) \), \( A \subseteq Z \). Since \( A^2 = E_2 = P \), there exists \( s \in P \setminus A \) such that \( A \subseteq (A : s) \). Let \( t \in (A : s) \setminus A \). Then \( Z \subseteq (A : t) \). So, \( (A : t)_Z = Q \). It follows that \( A_Z = tQ \). Hence \( E(U) \cong E(Q/tQ) \). From [5, Proposition 14], we deduce that \( E(R/Z) \) contains a pure uniserial submodule \( V \). Let \( x \in E(R/Z) \) such that \( Z = (0 : x) \). If \( G \) is an indecomposable injective module such that \( Z \subseteq G_2 \), \( \mathcal{A}(G) \) contains a faithful ideal \( B \). By [2, Proposition 6] \( V/Bx \) is a pure uniserial submodule of \( G \). \( \square \)
Let us observe that the condition (8) of Theorem 2.3 implies that each indecomposable injective module contains a pure uniserial submodule.

**Proposition 2.5.** Let \( R \) be a chain ring and let \( E \) be an indecomposable injective module such that \( P = E_1 \). Assume that \( E \) is polyserial. Then:

1. each indecomposable injective module \( G \) for which \( Z \subset G \) is polyserial;
2. for each prime ideal \( L \subset Z \), \( E(R/L) \) and \( E(R_L/aR_L) \) are polyserial, where \( a \in L \) with \( \neq aR_L \).

**Proof.** (1) holds by Lemma 2.4 and Theorem 2.3.

(2) holds by [2, Corollary 22] and Theorem 2.3.

**Remark 2.6.** If \( R \) is a chain ring which is not a domain, satisfying \( Mr\hat{R} < \infty \), then \( Mr\hat{R} = Mr\hat{R} \) even if \( R \subset \hat{R} \).

### 3. Fleischer rank and dual Goldie dimension of indecomposable injective modules

**Remark 3.1.** If \( M \) is a torsion-free module of finite rank over a valuation domain, it is easy to check that its Malcev rank is equal to its rank. So, if \( M \) is a module over a chain ring \( R \), then \( Fr M \) can be defined to be the minimum Malcev rank of flat modules having \( M \) as an epimorphic image. Obviously \( Mr M \leq Fr M \) for each module \( M \).

**Proposition 3.2.** Let \( R \) be a chain ring and let \( E \) be an indecomposable injective module such that \( E_1 \subset Z \). Then \( E \) is flat if \( A(E) \neq \{qR \mid r \in R\} \) then \( E \) is flat by [2, Proposition 8]. So, we may assume that \( A \) is not of the form \( rZ \) if \( A \in A(E) \). By [2, Lemma 26] \( A^2 = E_1 \) for each \( A \in A(E) \), so \( A \) is an ideal of \( Q \). It is easy to check that \( (0 : I) \) is also an ideal of \( Q \) for each ideal \( I \) of \( R \). In the sequel we apply [12, Proposition 1.3] to \( Q \): \( (0 : (0 : A)) \neq A \) if and only if \( A = qZ \) and \( (0 : (0 : A)) = qQ \) for some \( q \in Z \). Let \( r \in R \) and \( x \in E \) such that \( rx = 0 \). Then \( r \in A \) where \( A = \{0 : x\} \). Since \( rQ \subset A \), then \( (0 : A) \subset (0 : r) \). Let \( A = (0 : r) \setminus (0 : A) \). It follows that \( (0 : a) \subset (0 : (0 : A)) = A \). The injectivity of \( E \) implies that there exists \( y \in E \) such that \( x = ay \). So, \( E \) is flat.

**Proposition 3.3.** Let \( R \) be a chain ring. Assume that \( dR(L) < \infty \) and \( R_L \) is almost maximal for a prime ideal \( L \), and that \( E(R/Z) \) contains a pure uniserial submodule \( U \). Then \( Mr E = Fr E \) for each indecomposable injective module \( E \).

**Proof.** Let \( E \) be an indecomposable injective module and \( J = E_1 \). Since \( Mr E \leq Fr E \) it is enough to show that \( E \) is an epimorphic image of a flat module \( G \) with \( Mr E = Mr G \). First we assume that \( J \subset Z \). If \( Q \) is coherent then \( E \) is flat. If \( Q \) is not coherent and if \( E \neq E(Q/qQ) \), where \( 0 \neq q \in Z \), then \( E \) is flat by Proposition 3.2. If \( E = E(Q/qQ) \), then by [2, Proposition 14] there exists an epimorphism \( E(Q/Z) \to E \) whose kernel is a simple \( Q \)-module. It is easy to check that \( Mr E = Mr E(Q/Z) \), and \( E(Q/Z) \) is flat. Now, we assume that \( Z \subset J \). In this case, \( E \cong \hat{R}_J \otimes_R (U/Ax) \) where \( A \) is a faithful annihilator ideal of \( E \) and \( x \in U \) with \( Z = (0 : x) \). Moreover, \( U \) is flat because so is \( E(R/Z) \). Hence \( E \) is an epimorphic image of \( \hat{R}_J \otimes_R U \) which is flat. If \( R \) is not a domain.
then Mr $E = Mr \widehat{R}_J = Mr \widehat{R}_J \otimes_R U$. If $R$ is a domain, by Theorem 2.3 $\widehat{R}_J$ contains a pure submodule $F$ of rank equal to $Mr_R \widehat{R}_J$ such that $\widehat{R}_J/F$ is a divisible module. In this case we can take $U = Q$ and $x = 1$. Since $Q/A$ is a torsion module we have $E \cong F \otimes_R Q/A$. So, $E$ is a homomorphic image of $F \otimes_R Q$ and $Mr E = Mr \widehat{R}_J = Mr F \otimes_R Q$. \hfill \Box

We say that a submodule $K$ of a module $M$ is superfluous if the equality $K + G = M$ holds only when $G = M$. A module $M$ is co-uniform if each of its proper submodules is superfluous. We say that $M$ has dual Goldie dimension $n$ (or $dG M = n$) if there exists an epimorphism $\phi$ from $M$ into a direct sum of $n$ co-uniform modules such that $\ker \phi$ is superfluous.

**Proposition 3.4.** Let $R$ be a chain ring. Then $dG M \leq Mr M$ for each $R$-module $M$.

**Proof.** Let $n$ a positive integer such that $n \leq dG M$. Then there exists an epimorphism $\phi : M \to \bigoplus_{i=1}^{n} M_i$ where $M_i$ is a non-zero $R$-module for $i = 1, \ldots, n$. For each $i$, $1 \leq i \leq n$, let $x_i$ be a non-zero element of $M_i$ and let $y_i \in M$ such that $x_i = \phi(y_i)$. If $\sum_{i=1}^{n} a_i y_i = 0$ where $a_i \in R$ for $i = 1, \ldots, n$, we successively deduce that $\sum_{i=1}^{n} a_i x_i = 0$, $a_i x_i = 0$ and $a_i \in P$ for $i = 1, \ldots, n$. It follows that $Mr M \geq n$ for each integer $n \leq dG M$. So, $dG M \leq Mr M$. \hfill \Box

**Proposition 3.5.** Let $R$ be a chain ring. Suppose there exists a non-zero prime ideal $L$ such that $Z \subseteq L$, $d_R(L) < \infty$ and $R_L$ is almost maximal. Then each indecomposable injective module $E$ is polyserial and $Mr E = dG E$. \hfill \Box

**Proposition 3.6.** Let $R$ be a chain ring such that $Q$ is strongly discrete. Then each indecomposable injective module contains a pure uniserial submodule. For a such ring the nine conditions of Theorem 2.3 are equivalent.

**Proof.** Let $E$ be an indecomposable injective module and let $J = E_L$. First assume that $J \subseteq Z$. Since $J^2 \neq J$, $JR_J = aR_J$ where $a \in J \setminus J^2$. Recall that $E$ is a module over $R_J$. If $A \in \mathcal{A}(E)$ then $A^2 = J$ by [2, Lemma 26]. Since $JR_J$ is principal over $R_J$, so is $A$. Because $Z = sQ$ for some $s \in Z \setminus Z^2$, $(0 : Z) = (0 : s) \neq 0$. From [2, Corollary 22] we deduce that $E$ contains a pure uniserial submodule (which is isomorphic to $R_J$). If $Z \subset J$ we again use [2, Corollary 22] to conclude. \hfill \Box

**Corollary 3.7.** Let $R$ be a valuation domain. Then the nine conditions of Theorem 2.3 are equivalent. Moreover, for each indecomposable injective module $E$, $Mr E = Fr E = dG E = Mr \widehat{R}_J$, $\widehat{R}_J$ where $J = E_Z$. 

Example 3.8. It is possible to build examples of chain rings satisfying the nine equivalent conditions of Theorem 2.3 by using [8, Example 6 and Theorem 8]. These examples are strongly discrete (and Henselian). If \( R \) is a such example then \( \text{Mr}_R \hat{R} = p^n \), where \( p \) is a prime number and \( m \) a non-negative integer. By [18, Remark p.16] \( \text{Mr}_R \hat{R} \) is always a prime power.

4. Indecomposable injective modules over one Krull-dimensional local Noetherian rings

From a result by Marie-Paule Malliavin we deduce Theorem 4.1. If \( M \) is a module of finite length, we denote by \( \ell(M) \) its length.

Theorem 4.1. Let \( R \) be a one Krull-dimensional local Noetherian ring. There exists a positive integer \( n \) such that \( \text{Mr} E \leq n \) for each indecomposable injective \( R \)-module \( E \).

Proof. By [13, Théorème 1.4.2] \( \text{Mr} R \) is finite. We put \( m = \text{Mr} R \). Let \( E \) be an indecomposable injective module. Then there exists a prime ideal \( L \) such that \( E = E(R/L) \). First we assume that \( L \) is a minimal prime. It follows that \( E \) is a module of finite length over \( R_L \) by [14, Theorem 3.11(2)] since \( R_L \) is Artinian. In this case \( E \) has a composition series whose factors are isomorphic to \( R_L/\ell R_L \). It is easy to see that \( \text{Mr} R_L/\ell R_L = \text{Mr} R/L \leq m \). Now, by induction on the length of \( E \) over \( R_L \) and by using [10, Lemma XII.1.4] we get that \( \text{Mr} E < \infty \).

Now we assume that \( L = P \) the maximal ideal of \( R \). Let \( M \) be a finitely generated submodule of \( E \) and \( A = (0 : M) \). Since \( E \) is Artinian then \( M \) is a module of finite length and \( R/A \) is Artinian. By [1, Proposition 1.2] \( M \) is injective over \( R/A \) and \( R/A = \text{End}_R(M) \). Let \( B \) be the ideal of \( R \) such that \( B/A \) is the socle of \( R/A \). If \( p = \ell(B/A) \) then \( p = \text{gen} B \leq m \). So, there is an exact sequence \( 0 \rightarrow R/A \rightarrow M^p \) and by applying the functor \( \text{Hom}_{R/A}(-, M) \) to this sequence, we get that \( M \) is a homomorphic image of \( (R/A)^p \). So, \( \text{Mr} E \leq m \). Since the set of prime ideals of \( R \) is finite the theorem is proven.

Example 4.2. Let \( R \) be a local ring of maximal ideal \( P \) such that \( P^2 = 0 \). If \( \text{gen} P = n \) where \( n > 0 \) it is easy to check that \( \text{Mr} E(R/P) \leq n \).

In the sequel, for each integer \( n > 1 \) we shall give an example of a one Krull-dimensional local Noetherian domain \( D \) whose all finitely generated uniform modules are generated by at most \( n \) elements.

Example 4.3. Consider the Noetherian domain \( R \) defined in in the following way. Let \( K \) be a field, \( K[X,Y] \) the polynomial ring in two variables \( X \) and \( Y \), and \( f = Y^n - X^n(1 + X) \). By considering that \( f \) is a polynomial in one variable \( Y \) with coefficients in \( K[X] \), it follows from Eisenstein’s criterion that \( f \) is irreducible.

Then \( D = K[X,Y]/fK[X,Y] \) is a domain. Let \( x \) and \( y \) be the images of \( X \) and \( Y \) in \( D \) by the natural map and \( P' \) the maximal ideal of \( D \) generated by \( \{x, y\} \). Let \( R = D_{P'} \) and \( P = P'R \).

Then \( \text{Mr} R = n \) and \( \text{Mr} E = n \) for each indecomposable injective \( R \)-module \( E \).
There are only two types of indecomposable injective modules: \(E(R/P)\) and 
\(Q\) the quotient field of \(D\) and \(R\). Let \(M\) be a finitely generated submodule of \(Q\).
Then \(M\) is isomorphic to an ideal of \(R\). As a module over over \(K[X]\) \(D\) is generated by \(n\) elements \(1, y, y^2, \ldots, y^{n-1}\). Since \(K[X]\) is a principal ideal domain, by [20, Lemma 1.3] each \(K[X]\)-submodule of \(D\) is generated by at most \(n\) elements. It follows that each ideal of \(D\) and each ideal of \(R\) is generated by at most \(n\) elements.
Let us observe that \(\text{gen} \ P^m = n\) for each \(m \geq n - 1\). So, \(\text{Mr } E(R/P) \leq n\), and since \(\text{gen} \ P^{n-1} = n\) we have \(\text{gen} \text{Hom}_R(R/P^n, E(R/P)) = n\). The proof is now complete. \(\square\)

5. Goldie dimension and localization

At the beginning of this section \(R\) is not necessarily a chain ring.

**Proposition 5.1.** Let \(R\) be a ring satisfying one of the following two conditions:

(1) \(R_P\) is a one Krull-dimensional domain for each maximal ideal \(P\);

(2) \(R_P\) is Noetherian for each maximal ideal \(P\).

Then, \(S^{-1}M\) has finite Goldie dimension for each \(R\)-module \(M\) of finite Goldie dimension and for each multiplicative subset \(S\) of \(R\).

**Proof.** If \(\text{Gd } M < \infty\) then \(M\) is a submodule of a finite direct sum of indecomposable injective modules \((E_i)_{1 \leq i \leq n}\). It follows that \(\text{Gd } S^{-1}M < \infty\) if and only if \(\text{Gd } S^{-1}E_i < \infty\) for \(i = 1, \ldots, n\). So, we may assume that \(M\) is injective and indecomposable. On the other hand, since \(\text{End}_R(M)\) is a local ring, there exists a maximal ideal \(P\) such that \(M\) is a module over \(R_P\). So, we may assume that \(R\) is local of maximal ideal \(P\).

If \(R\) satisfies (1) then \(S = R \setminus \{0\}\). Either \(M\) is torsion-free and \(S^{-1}M = M\), or \(M\) is torsion and \(S^{-1}M = 0\).

If \(R\) satisfies (2), we may assume that \(M = E(R/P)\) and \(S \cap P \neq \emptyset\). Let \(\phi\) be the natural map \(M \to S^{-1}M\). Since \(M\) is artinian by [14, Corollary 3.4] then so is the image of \(\phi\). It follows that \(S^{-1}M\) is an essential extension of a semisimple module \(X\). But, for each \(s \in S \cap P\), \(sX = 0\). We conclude that \(S^{-1}M = 0\). \(\square\)

**Proposition 5.2.** Let \(R\) be a zero Krull-dimensional ring. Then \(\text{dG } S^{-1}M < \infty\) for each module \(M\) with \(\text{dG } M < \infty\) and for each multiplicative subset \(S\) of \(R\).

**Proof.** Since the natural maps \(R \to S^{-1}R\) and \(M \to S^{-1}M\) are surjective then \(\text{dG } S^{-1}M \leq \text{dG } M\). \(\square\)

**Example 5.3.** Let \(R\) be a local two Krull-dimensional UFD, \(p\) a prime element of \(R\) and \(S = \{p^n \mid n \in \mathbb{N}\}\). Then \(\text{dG } R = 1\) and \(\text{dG } S^{-1}R = \infty\).

**Proof.** The first equality is obvious. Let \(\Phi\) be the set of prime elements of \(R\). If \(P\) is the maximal ideal of \(R\) then \(P = \bigcup_{q \in \Phi} Rq\). So, \(\Phi\) is not finite, else, by a classical lemma \(P = Rq\) for some \(q \in \Phi\) that is impossible. Let \(n\) be a positive integer, let \(q_1, \ldots, q_n\) be \(n\) distinct elements of \(\Phi \setminus \{p\}\) and let \(a = q_1 \times \cdots \times q_n\). By the chinese remainder theorem \(S^{-1}R/\alpha S^{-1}R \cong S^{-1}R/q_1 S^{-1}R \times \cdots \times S^{-1}R/q_n S^{-1}R\). So, \(\text{dG } S^{-1}R \geq n\) for each \(n > 0\). \(\square\)

**Theorem 5.4.** Let \(R\) be a chain ring. The following conditions are equivalent:
(1) For each module $M$ of finite Goldie dimension and for each prime ideal $L$, $M_L$ has finite Goldie dimension;
(2) for each prime ideal $L \neq 0$, $d_R(L)$ is finite.

Proof. (1) $\Rightarrow$ (2). By way of contradiction suppose there exists a non-zero ideal $L$ such that $d_R(L) = \infty$. Then, for each positive integer $n$, $\hat{R}/L\hat{R}$ contains a torsion-free $R/L$-module $F$ of rank $n$. Let $A$ be an ideal such that $A^2 = P$ and $A \subset L$. By [5, Proposition 1.2] $\hat{R}/A\hat{R}$ is isomorphic to a submodule of the injective hull $E$ of $R/A$. Since $F_L$ is a $(R/L)_L$-vector space of dimension $n$ contained in $(\hat{R}/L\hat{R})_L$, we deduce from [6, Proposition 21], applied to $(\hat{R}/A\hat{R})_L$ that $E_L$ contains a free $(R/A)_L$-module of rank $n$. So, $\text{Gd } E_L \geq n$ for each integer $n$.

(2) $\Rightarrow$ (1). It is sufficient to show that $\text{Gd } E_L < \infty$ for each indecomposable injective module $E$ and each non-zero prime ideal $L$. Let $J = E_0$. If $J \subset L$, then $E$ is a module over $R_J$, whence $E_L = E$. If $L \subset J$, since $d_{R_J}(L_J) < d_R(L)$, after replacing $R_J$ by $R$, we may assume that $J = P$. If $L = 0$ (in the case where $R$ is a domain) then $E_L = 0$. By [2, Corollary 28] $E$ is either faithful or annihilated by a simple ideal. So, if $L \neq 0$, there exists $A \in \mathcal{A}(E)$ such that $A \subset L$. We put $E' = (0 : E A)$. First we show that $E'_L$ is essential in $E_L$. Let $x \in E$ such that $x \frac{1}{1} \notin E'_L$. Then $x \notin E'$. So, $(0 : x) = r A$ where $r \in P$. It follows that $(0 : rx) = A$. We conclude that $r \frac{x}{1} \in E'_L$ and $r \frac{x}{1} \neq 0$. Let $d = d_R(L)$. Then $(\hat{R})_L/(R/L)_L \cong (R/L)_L^d$. Since $P/A$ is the set of zero-divisors of $R/A$ then $(R/A)_L$ is self FP-injective by [2, Theorem 11(2)]. From [5, Proposition 1] it is easy to deduce that $\hat{R}/A$ is singly projective over $R/A$. By [6, Proposition 6] so that is $(\hat{R}/A)_L$ over $(R/A)_L$. By [6, Propositions 24 and 21] $E'_{L}$ (which is isomorphic to $(\hat{R}/A)_L$) contains an essential free $(R/A)_L$-submodule of rank $d$. We conclude that $\text{Gd } E_L = d < \infty$.

**Corollary 5.5.** Let $R$ be a chain ring and let $J$ be the intersection of all non-zero prime ideals. Then $J$ is prime (= $N$ if $R$ is not a domain) and the following assertions hold:

- (1) if $J \neq 0$ then Goldie dimension finiteness is preserved by localization if and only if $d_R(J)$ is finite;
- (2) if $J = 0$ and if $0$ is a non countable intersection of non-zero prime ideals then Goldie dimension finiteness is preserved by localization if and only if there exists a non-zero prime ideal $L$ such that $d_R(L)$ is finite and $R_L$ is almost maximal.

**Proof.** (1) is an immediate consequence of Theorem 5.4.

(2). First we will show that there exists a positive integer $p$ such that $d_R(L) \leq p$ for each non-zero prime ideal $L$. By way of contradiction suppose there exists a non-zero prime ideal $L_n$ such that $d_R(L_n) \geq n$, for each integer $n > 0$. Let $H = \cap_{n>0}L_n$. Then $H$ is a non-zero prime ideal and $d_R(H) \geq n$ for each integer $n > 0$. We get a contradiction by Theorem 5.4. Let $p$ be the maximum of $d_R(I)$ where $I$ runs over all non-zero prime ideals of $R$ and let $L$ be the maximal prime ideal for which $d_R(L) = p$. If $L'$ is a non-zero prime ideal, $L' \subset L$, then $Mr \hat{R}/L' = p$. By Theorem 2.2 $R_L/L'$ is maximal. We conclude that $R_L$ is almost maximal. □

Let us observe that the following conditions:
(1) each indecomposable injective $R$-module is polyserial;
(2) the Goldie dimension finiteness is preserved by localization;

are equivalent if $R$ is a valuation domain such that 0 is a non countable intersection of non-zero prime ideals. But, generally these two conditions are not equivalent. For instance, if $J \neq 0$, $d_R(J) < \infty$ and $R_{J}$ not almost maximal, where $J$ is the intersection of all non-zero prime ideals, then $R$ satisfies condition (2) but not condition (1). Another example of a chain ring satisfying condition (2) but not condition (1) is the following:

Example 5.6. Let $R$ be a strongly valuation domain whose set of non-zero prime ideals is $\{L_n | n \in \mathbb{N}\}$ with $L_0 = P$ and $L_{n+1} \subset L_n$ for each $n \in \mathbb{N}$. Moreover we assume that $c_R(L_n) = p$ for each $0 \neq n \in \mathbb{N}$, where $p$ is a prime integer. A such ring $R$ exists by [8, Theorem 8]. For each integer $n > 0$, $d_R(L_n) = p^n$. So, condition (2) is satisfied by Theorem 5.4. But condition (1) doesn’t hold because there is no non-zero prime ideal $L$ with $R_L$ almost maximal.
