BLOK-ESAKIA THEOREMS VIA STABLE CANONICAL RULES

NICK BEZHANISHVILI AND ANTONIO M. CLEANI

ABSTRACT. We present a new uniform method for studying modal companions of superintuitionistic rule systems and related notions, based on the machinery of stable canonical rules. Using this method, we obtain alternative proofs of the Blok-Esakia theorem and of the Dummett-Lemmon conjecture for rule systems. Since stable canonical rules may be developed for any rule system admitting filtration, our method generalizes smoothly to richer signatures. Using essentially the same argument, we obtain a proof of an analogue of the Blok-Esakia theorem for bi-superintuitionistic and tense rule systems, and of the Kuznetsov-Muravitsky isomorphism between rule systems extending the modal intuitionistic logic $\mathbb{K}\mathbb{M}$ and modal rule systems extending the provability logic $\mathbb{GL}$. In addition, our proof of the Dummett-Lemmon conjecture also generalizes to the bi-superintuitionistic and tense cases.

INTRODUCTION

A modal companion of a superintuitionistic logic $L$ is defined as any normal modal logic $M$ extending $\mathcal{S}4$ such that the Gödel translation fully and faithfully embeds $L$ into $M$. The notion of a modal companion has sparked a remarkably prolific line of research, documented, e.g., in the surveys [12] and [45]. The jewel of this research line is the celebrated Blok-Esakia theorem, first proved independently by Blok [9] and Esakia [20]. The theorem states that the lattice of superintuitionistic logics is isomorphic to the lattice of normal extensions of Grzegorczyk’s modal logic $\mathcal{G}rz$, via the mapping which sends each superintuitionistic logic $L$ to the normal extension of $\mathcal{G}rz$ with the set of all Gödel translations of formulae in $L$.

Zakharyaschev [46] developed a unified approach to the theory of modal companions, via his technique of canonical formulae. These formulae generalize the subframe formulae of Fine [23]. Like a subframe formula, a canonical formula syntactically encodes the structure of a finite refutation pattern, i.e., a finite transitive frame together with a (possibly empty) set of parameters. By applying a version of the selective filtration construction, every formula can be matched with a finite set of finite refutation patterns, in such a way that the conjunction of all the canonical formulae associated with the refutation patterns is equivalent to the original formula. By studying how the Gödel translation affects superintuitionistic canonical formulae, Zakharyaschev gave alternative proofs of classic theorems in the theory of modal companions, and extended this theory with several novel results. Among these, he confirmed the Dummett-Lemmon conjecture, formulated in [17], which states that a superintuitionistic logic is Kripke complete iff its weakest modal companion is. Jeřábek [27] generalized canonical formulae to canonical rules, and applied this notion to extend Zakharyaschev’s approach to theory of modal companions to rule systems (also known as multi-conclusion consequence relations.)
In [4, 5, 2], stable canonical formulae and rules were introduced as an alternative to Zakharyaschev and Jeřábek-style canonical rules and formulae. The basic idea is the same: a stable canonical formula or rule syntactically encodes the semantic structure of a finite refutation pattern. The main difference lies in how such structure is encoded, which affects how refutation patterns are constructed in the process of rewriting a formula (or rule) into a conjunction of stable canonical formulae (or rules). Namely, in the case of stable canonical formulae and rules finite refutation patterns are constructed by taking filtrations rather than selective filtrations of countermodels. A survey of stable canonical formulae and rules can be found in [3].

In this paper, we apply stable canonical rules to develop a novel, uniform approach to the study of modal companions and similar notions in richer signatures. Our approach echoes the Zakharyaschev-Jeřábek approach in using rules encoding finite refutation patterns, but also bears circumscribed similarities with Blok’s original algebraic approach in some proof strategies (see Remark 4.3). Our techniques deliver central results in the theory of modal companions through transparent arguments. In particular, we obtain an alternative proof of the Blok-Esakia theorem for both logics and rule systems, and generalize the Dummett-Lemmon conjecture to rule systems.

Due to the flexibility of filtration, our techniques generalize smoothly to rule systems in richer signatures. To illustrate this, we apply our method to the study of tense companions of bi-superintuitionistic deductive systems and to the study of (mono)modal companions of modal intuitionistic rule systems above KM. In each of these cases, we prove analogues of the Blok-Esakia theorem. When restricted to logics, these results were proved, respectively, by Wolter [42, Theorem 23] and [30, Proposition 3], though they appear to be new for rule systems. In the case of tense companions, in addition, we also prove an analogue of the Dummett-Lemmon conjecture for rule systems, which also appears to be novel.

Notably, in each of these three cases, our main results are proved by essentially the same arguments. By contrast, generalizing the Zakharyaschev-Jeřábek technique beyond the case of modal companions of superintuitionistic logics is far from straightforward. In particular, as we argue towards the end of Section 3, it is far from clear whether the Zakharyaschev-Jeřábek technique generalizes to the case of tense companion, since selective filtration does not work well for bi-superintuitionistic and tense logics.

The techniques described in this paper can also be used to obtain axiomatic characterizations of the modal companion maps (and their counterparts in the richer signatures discussed here) in terms of stable canonical rules, as well as some results concerning the notion of stability [6]. These results can be found in the recent master’s thesis [14], on which the present paper is based.

The paper is organized as follows. We begin by reviewing some general preliminaries in Section 1, followed by the basic constructions in the theory of modal companions in Section 2. We then introduce stable canonical rules in Section 3, generalizing known constructions to the bi-superintuitionistic and tense case. In Section 4 we present our proof of a general Blok-Esakia theorem, which uniformly applies to each of the three notions of companions we are interested in. Finally, in Section 5 we present our proof of a general Dummett-Lemmon conjecture, applying to both modal and tense companions. We conclude in Section 6.
1. Preliminaries

We review some basic facts about rule systems and their interpretation over algebras, topological spaces and Kripke frames. The reader may consult the following references for more detailed information: [25] for rule systems in general; [13, 27] for modal and superintuitionistic rule systems; [10] for universal algebra; [28, 22] for duality theory.

1.1. Rule Systems. Throughout the paper we fix a countably infinite set of propositional variables $Prop$. For a signature $\nu$ (a finite set of propositional connectives), the set of $\nu$-formulae is built from $Prop$ using the connectives in $\nu$ in the usual way.

A substitution is a map $s : Frm_\nu(Prop) \to Frm_\nu(Prop)$ which commutes with the operators in $\nu$.

A rule in signature $\nu$ is a pair $(\Gamma, \Delta)$ such that $\Gamma, \Delta$ are finite subsets of $Frm_\nu$. In case $\Delta = \{\phi\}$ we write $\Gamma/\phi$ simply as $\Gamma\phi$, and analogously if $\Gamma = \{\psi\}$. Moreover, we write $/\phi$ for the rule $\emptyset/\phi$. A rule is said to be single-conclusion when of the form $\Gamma/\phi$, and assumption free when of the form $/\Delta$. We use $;$ to denote union between finite sets of formulae, so that $\Gamma; \Delta = \Gamma \cup \Delta$ and $\Gamma; \phi = \Gamma \cup \phi$.

Definition 1.1. A rule system $S$ in signature $\nu$ is a set $S \subseteq Rul_\nu$ satisfying the following conditions:

1. If $\Gamma/\Delta \in S$, then $s[\Gamma]/s[\Delta] \in S$ for all substitutions $s$ (structurality);
2. $\psi/\psi \in S$ for every formula $\psi$ (reflexivity);
3. If $\Gamma/\Delta \in S$, then $\Gamma; \Gamma'/\Delta; \Delta' \in S$ for any finite sets of formulae $\Gamma', \Delta'$ (monotonicity);
4. If $\Gamma/\Delta; \psi \in S$ and $\Gamma; \psi/\Delta \in S$, then $\Gamma/\Delta \in S$ (cut).

If $S$ is a set of rule systems and $\Sigma, \Xi$ are sets of rules, we write $\Xi \oplus S \Sigma$ for the least rule system in $S$, if it exists, extending both $\Xi$ and $\Sigma$. A set of rules $\Sigma$ is said to axiomatize a rule system $S \in S$ over some rule system $S' \in S$ if $S' \oplus S \Sigma = S$. When $S$ is clear from context, we write simply $\oplus$ instead of $\oplus_S$.

In this paper we will work with rule systems in 5 different signatures.

- The modal signature $m := \{\land, \neg, \bot, \Box\}$;
- The tense signature $t := \{\land, \neg, \bot, \Box, \Diamond\}$;
- The superintuitionistic (si) signature $si := \{\land, \lor, \rightarrow, \bot, \top\}$;
- The bi-superintuitionistic (bsi) signature $bsi := \{\land, \lor, \rightarrow, \leftarrow, \bot, \top\}$;
- The modal superintuitionistic (msi) signature $msi := \{\land, \lor, \rightarrow, \Box, \top, \bot\}$.

When working in the modal and tense signatures, we will treat the other Boolean and modal connectives as defined in the usual way. We will denote the duals of $\Box$ and $\Diamond$ as $\Diamond$ and $\blacksquare$ respectively. In the bsi signature we also use the abbreviations

$p := p \rightarrow \bot, \quad \neg p := \top \leftarrow p.$

For each unary propositional connective $\lhd$, we define the rules

\[(K\lhd) \quad \phi/\lhd \phi, \]
\[(Nec\lhd) \quad \phi/\lhd \phi.\]
A normal modal rule system is a rule system in the signature $m$ containing the rule $\phi$ whenever $\phi$ is a theorem of the Classical Propositional Calculus, as well as the rules ($K\Box$), ($\Box\neg\neg$) and

\[(\text{MP}) \quad \phi \rightarrow \psi, \phi/\psi.\]

A normal tense rule system is a rule system in the signature $t$, whose $\Box$-free and $\Diamond$-free fragments are each a normal modal rule system and which, in addition, contains the rule

\[(t) \quad \phi \rightarrow \Box\Diamond\phi.\]

We will henceforth omit the prefix “normal.”

A si rule system is a rule system in the signature $si$ containing the rule $\phi$ whenever $\phi$ is a theorem of the intuitionistic propositional calculus IPC, as well as the rule (MP). A bsi rule system is a rule system in the signature containing the rule $\phi/\phi$ whenever $\phi$ is a theorem of the bi-intuitionistic propositional calculus biIPC, as well as the rules (MP) and (Nec$_{\neg\neg}$). We refer the reader to [13, Ch. 12] and [35] for explicit axiomatizations of IPC and biIPC respectively.

Finally, a msi rule system is a rule system in the signature $msi$, whose $si$ fragment is a si rule system and which, in addition, contains the rules ($K\Diamond$) and (Nec$_\Diamond$), as well as the following:

\[(1) \quad \phi \rightarrow \Box\phi\]
\[(2) \quad \Box\phi \rightarrow (q \lor (q \rightarrow p)).\]

When $M$ is a modal (resp. tense, msi) rule system, we write $\text{NExt}(M)$ for the class of all modal (resp. tense, msi) rule systems extending $M$. Similarly, when $L$ is a si or bsi rule system, we write $\text{Ext}(L)$ for the class of all si or bsi rule systems extending $L$. We note that all these classes of rule systems form complete lattices, where the meet is intersection and the join is given by the $\oplus$ operation over the relevant class of rule systems.

A (modal, tense, si, bsi or msi) logic is a (modal, tense, si, bsi or msi) rule system which can be axiomatized, over the least rule system of the same kind, by a set of assumption-free, single conclusion rules. Logics in this sense correspond one-to-one with logics conceived of as sets of formulae closed under appropriate conditions, a conception that much of the literature in the field of modal and superintuitionistic logic shares. For example, the (normal) modal logics in the standard sense [e.g., 13, p. 113] correspond one-to-one with the normal modal rule systems axiomatizable by assumption-free, single conclusion rules. When $M$ is a modal logic in this sense, there is always a corresponding modal rule system $/M$ axiomatized by $\{/\phi : \phi \in M\}$. Conversely, for any modal rule system $N$ the set $\{\phi : /\phi \in N\}$ is always a modal logic in the standard sense. Moreover, as is clear from the definition of the $\oplus$ operation, the set of rule systems of a given kind which admit an assumption-free, single conclusion axiomatization is a sublattice of the lattice of all rule systems of the same kind. When $\text{NExt}(M)$ (resp. $\text{Ext}(L)$) is a lattice of rule systems, we denote the corresponding sublattice of logics as $\text{NExtL}(M)$ (resp. $\text{ExtL}(L)$).

**Convention 1.2.** In view of this correspondence, we will use familiar names for standard logics in the literature to refer to the corresponding rule system: that is, when $L$ names a standard (modal, tense, si, bsi or msi) logic we shall identify $L$ with the rule system $/L$ defined as above. Thus, for example, we write $K$ for the least modal rule system, IPC for the least si rule system, and so on.
Throughout the paper we will refer to a number of standard rule systems. We collect all of them in Table 1.

| Rule Systems         | Description |
|----------------------|-------------|
| **Modal rule systems** |             |
| \(K\)                | The least modal rule system |
| \(K4\)               | \(K \oplus /\Box p \to \Box \Box p\) |
| \(S4\)               | \(K4 \oplus /\Box p \to p\) |
| \(Grz\)              | \(S4 \oplus /\Box (\Box (p \to \Box p) \to p) \to p\) |
| \(GL\)               | \(K4 \oplus /\Box (\Box p \to p) \to \Box p\) |
| **Si and bsi rule systems** |             |
| \(IPC\)              | The least si rule system |
| \(biIPC\)            | The least bsi rule system |
| **Tense rule systems** |             |
| \(K.t\)              | The least tense rule system |
| \(K4.t\)             | \(K4 \oplus /\Box p \to \Box \Box p \oplus /\Diamond p \to \Diamond p\) |
| \(S4.t\)             | \(K4 \oplus /\Box p \to p \oplus /p \to \Diamond p \to (p \land \neg \Diamond (\Diamond p \land \neg p))\) |
| \(Grz.t\)            | \(S4 \oplus /\Box ((p \to \Box p) \to p) \to p \oplus /p \to \Diamond (p \land \neg \Diamond (\Diamond p \land \neg p))\) |
| **Msri rule systems**  |             |
| \(IPCK\)             | The least msri rule system |
| \(KM\)               | \(IPCK \oplus /\Box p \to p\) |

Table 1. Standard rule systems

1.2. **Algebraic Semantics.** We interpret rule systems over algebras in the same signature. If \(A\) is a \(\nu\)-algebra, we denote its carrier as \(A\). Let \(A\) be some \(\nu\)-algebra. A valuation on \(A\) is a map \(V : \text{ Frm}_\nu \to A\), satisfying the condition

\[
V(f(\phi_1, \ldots, \phi_n)) := f^A(V(\phi_1), \ldots, V(\phi_n))
\]

for each \(f \in \nu\). A pair \((A, V)\) where \(A\) is a \(\nu\)-algebra and \(V\) a valuation on \(A\) is called a model. A model \((A, V)\) satisfies a rule \(\Gamma/\Delta\) when the following holds: if \(V(\gamma) = 1\) for all \(\gamma \in \Gamma\), then \(V(\delta) = 1\) for some \(\delta \in \Delta\). In this case, we write \(A, V \models \Gamma/\Delta\). A rule \(\Gamma/\Delta\) is valid on a \(\nu\)-algebra \(A\) when \(A, V \models \Gamma/\Delta\) holds for all valuations \(V\) on \(A\). When this holds we write \(A \models \Gamma/\Delta\), otherwise we write \(A \not\models \Gamma/\Delta\) and say that \(A\) refutes \(\Gamma/\Delta\). We can extend this notion of validity to classes of \(\nu\)-algebras in the obvious way.

Write \(A_\nu\) for the class of all \(\nu\)-algebras. For every rule system \(S\) we define

\[
\text{Alg}(S) := \{ A_\nu : A \models S \}.
\]

Conversely, if \(K\) is a class of \(\nu\)-algebras we set

\[
\text{ThR}(K) := \{ \Gamma/\Delta \in \text{ Rul}_\nu : K \models \Gamma/\Delta \}.
\]

A variety (resp. universal class) of \(\nu\)-algebras is a class of \(\nu\)-algebras closed under homomorphic images, subalgebras and direct products (resp. under isomorphic copies, subalgebras and ultraproducts). When \(S\) is a class of \(\nu\)-algebras we write
\textbf{Var}(\mathcal{S})$ and $\textbf{Uni}(\mathcal{S})$ respectively for the class of subvarieties and of universal subclasses of $\mathcal{S}$. It is well known that both $\textbf{Var}(\mathcal{S})$ and $\textbf{Uni}(\mathcal{S})$ admit the structure of a complete lattice.

Throughout the paper we study the structure of lattices of rule systems via semantic methods. This is made possible by the following fundamental result, connecting the syntactic types of rule systems to closure conditions on the classes of algebras validating them. Item 1 is widely known as \textit{Birkhoff’s theorem}, after [8].

\textbf{Theorem 1.3} ([10, Theorems II.11.9 and V.2.20]). For every class $\mathcal{K}$ of $\nu$-algebras, the following conditions hold:

1. $\mathcal{K}$ is a variety iff $\mathcal{K} = \textbf{Alg}(\mathcal{S})$ for some set of $\nu$-formulae $\mathcal{S}$.
2. $\mathcal{K}$ is a universal class iff $\mathcal{K} = \textbf{Alg}(\mathcal{S})$ for some set of $\nu$-rules $\mathcal{S}$.

In this sense, $\nu$-logics correspond to varieties of $\nu$-algebras, whereas $\nu$-rule systems correspond to universal classes of $\nu$-algebras.

We now briefly describe the classes of alegbras we shall use to interpret the rule systems under discussion in more detail, and review some of their basic properties. For further details on these structures, we point the reader to [22, 13, 36, 34, 29, 40, 21].

A \textit{Heyting algebra} is a tuple $H = (H, \wedge, \vee, \rightarrow, 0, 1)$ such that $(H, \wedge, \vee, 0, 1)$ is a bounded distributive lattice and for every $a, b, c \in H$ we have

$c \leq a \rightarrow b \iff a \land c \leq b$.

A \textit{bi-Heyting algebra} is a tuple $H = (H, \wedge, \vee, \rightarrow, \leftarrow, 0, 1)$ such that the $\leftarrow$-free reduct of $H$ is a Heyting algebras, and such that for all $a, b, c \in H$ we have

$a \leftarrow b \leq c \iff a \leq b \lor c$.

Equivalently, a bi-Heyting algebra can be defined as a Heyting algebra $H$ whose order dual is also a Heyting algebra, whose implication is defined by the identity

$a \leftarrow b := \bigwedge \{c \in H : a \leq b \lor c\}$.

A \textit{modal} algebra is a tuple $\mathfrak{M} = (M, \wedge, \vee, \neg, \Box, 0, 1)$ such that $(M, \wedge, \vee, \neg, 0, 1)$ is a Boolean algebra and the following equations hold:

\begin{align*}
(3) & \quad \Box 1 = 1, \\
(4) & \quad \Box(a \land b) = \Box a \land \Box b.
\end{align*}

In any modal algebra $\mathfrak{M}$ we can define the compound modality

(5) $\Box^+ a := \Box a \land a$.

A \textit{tense algebra} is a structure $\mathfrak{M} = (M, \wedge, \vee, \neg, \Box, \Diamond, 0, 1)$, such that both the $\Box$-free and the $\Diamond$-free reducts of $\mathfrak{M}$ are both modal algebras, and $\Box, \Diamond$ form a residual pair, that is, for all $a, b \in M$ we have the following identity:

(6) $\Diamond a \leq b \iff a \leq \Box y$.

Finally, a \textit{frontal Heyting algebra} $\mathcal{F} = (H, \wedge, \vee, \rightarrow, \bigboxtimes, 0, 1)$ whose $\bigboxtimes$-free reduct is a Heyting algebra and such that $\bigboxtimes$ satisfies the identities (3) and (4), as well as the following inequalities:

\begin{align*}
(7) & \quad a \leq \bigboxtimes a, \\
(8) & \quad \bigboxtimes a \leq b \lor (b \rightarrow a).
\end{align*}
We write HA, biHA, MA, Ten, FHA for the classes of Heyting algebras, bi-Heyting algebras, modal algebras, tense algebras and frontal Heyting algebras respectively. It is well known that all these classes are equationally definable, hence varieties by (1.3). What is more, their universal subclasses are algebraic counterparts of the rule systems introduced in the previous subsection, in the sense spelled out by the following theorem.

**Theorem 1.4.** The following maps are pairs of mutually inverse dual isomorphisms:

- \( \text{Alg} : \text{Ext}(IPC) \to \text{Uni}(HA) \) and \( \text{ThR} : \text{Uni}(HA) \to \text{Ext}(IPC) \).
- \( \text{Alg} : \text{Ext}(biIPC) \to \text{Uni}(biHA) \) and \( \text{ThR} : \text{Uni}(biHA) \to \text{Ext}(biIPC) \).
- \( \text{Alg} : \text{NExt}(K) \to \text{Uni}(MA) \) and \( \text{ThR} : \text{Uni}(MA) \to \text{NExt}(K) \).
- \( \text{Alg} : \text{NExt}(K,t) \to \text{Uni}(Ten) \) and \( \text{ThR} : \text{Uni}(Ten) \to \text{NExt}(K,t) \).
- \( \text{Alg} : \text{NExt}(IPCK) \to \text{Uni}(FHA) \) and \( \text{ThR} : \text{Uni}(FHA) \to \text{NExt}(IPCK) \).

**Corollary 1.5.** Every si (resp. bsi, modal, tense, msi) rule system \( L \) is complete with respect of some universal class of Heyting (resp. bi-Heyting, modal, tense, frontal Heyting) algebras. Moreover, if \( L \) is a logic, then (by Theorem 1.3) it is complete with respect to a variety of algebras of the appropriate kind.

Lastly, we introduce some uniform notation to refer to the non truth-functional operations of a \( \nu \)-algebra. For \( \mathfrak{A} \) a \( \nu \)-algebra, let

\[
op(\mathfrak{A}) := \begin{cases} 
\{\to\} & \text{if } \mathfrak{A} \in \text{HA} \\
\{\to, \leftarrow\} & \text{if } \mathfrak{A} \in \text{biHA} \\
\{\Box\} & \text{if } \mathfrak{A} \in \text{MA} \\
\{\Box, \Diamond\} & \text{if } \mathfrak{A} \in \text{Ten} \\
\{\to, \Box\} & \text{if } \mathfrak{A} \in \text{FHA}
\end{cases}
\]

### 1.3. Geometric Semantics and Duality.

All the rule systems mentioned so far also admit a more suggestive geometric-topological semantics, which we shall rely on in the proofs of several results. We sketch this semantics here and relate the basic topological structures it involves to their algebraic counterparts.

A **Stone space** is a compact Hausdorff space with a basis of clopens. The topological structures we shall work with are all expansions of Stone spaces with one or more binary relations satisfying various conditions. For each of the signatures \( \nu \) presented earlier, there is a corresponding class of such spaces, which for the moment we call \( \nu \)-spaces. When \( \mathcal{X} := (X, \preceq_1, \ldots, \preceq_n, O) \) is a \( \nu \)-space we let \( \text{Clop}(\mathcal{X}) \) denote the set of clopen subsets of \( \mathcal{X} \), and let \( \text{ClopUp}_I(\mathcal{X}) \) denote the set of clopen upsets of \( \mathcal{X} \) with respect to the relation \( \preceq_I \), i.e., those elements of \( \text{Clop}(\mathcal{X}) \) which are upward-closed with respect to the relation \( \preceq_I \). Moreover, for \( U \subseteq X \) we write

\[
\uparrow_{\preceq_I} U := \{ x \in X : y \preceq_I x \text{ for some } y \in U \},
\]
\[
\downarrow_{\preceq_I} U := \{ x \in X : x \preceq_I y \text{ for some } y \in U \}.
\]

In case \( U = \{ x \} \) we write \( \uparrow_{\preceq_I} x \) and \( \downarrow_{\preceq_I} x \) instead of \( \uparrow_{\preceq_I} \{ x \} \) and \( \downarrow_{\preceq_I} \{ x \} \). When the space in question is only equipped with one relation or when the relation in question is clear from context, we may omit the subscripts from any of these operations.
We now describe these spaces in more detail. An Esakia space is a triple \( \mathfrak{X} = (X, \leq, \mathcal{O}) \) such that \( (X, \mathcal{O}) \) is a Stone space and \( \leq \) is a reflexive and transitive relation satisfying the following conditions:

1. \( \downarrow x \) is closed for every \( x \in X \);
2. \( \downarrow U \in \text{Clop}(\mathfrak{X}) \) for every \( U \in \text{Clop}(\mathfrak{X}) \).

If, in addition, the structure \( \mathfrak{X}^{-1} = (X, \geq, \mathcal{O}) \) is also an Esakia space, where \( \geq \) is the converse of \( \leq \), then we call \( \mathfrak{X} \) a bi-Esakia space.

A modal space is a triple \( \mathfrak{X} = (X, R, \mathcal{O}) \) such that \( (X, \mathcal{O}) \) is a Stone space and \( R \) is a binary relation—not necessarily reflexive and transitive—satisfying conditions (1) and (2) above. When the structure \( \mathfrak{X}^{-1} = (X, \bar{R}, \mathcal{O}) \) is also a modal space, where \( \bar{R} \) is the converse of \( R \), we call \( \mathfrak{X} \) a tense space.

Finally, a modalized Esakia space is a quadruple \( \mathfrak{X} = (X, \leq, \sqsubseteq, \mathcal{O}) \) such that \( (X, \leq, \mathcal{O}) \) is an Esakia space and the following conditions hold:

1. \( \{ x \in X : \downarrow x \subseteq U \} \in \text{Clop}_{\leq}(\mathfrak{X}) \) whenever \( U \in \text{Clop}_{\leq}(\mathfrak{X}) \);
2. The reflexive closure of \( \sqsubseteq \) coincides with \( \leq \).

Let \( \mathfrak{X} = (X, \leq_1, \ldots, \leq_n, \mathcal{O}) \) and \( \mathfrak{X}' = (X', \leq'_1, \ldots, \leq'_n, \mathcal{O}') \) be \( \nu \)-spaces. A mapping \( f : \mathfrak{X} \to \mathfrak{X}' \) is called a \( \nu \) bounded morphism when it is continuous and satisfies the conditions below for all \( x, y \in X \) and each \( i \leq n \):

1. \( x \leq_i y \) only if \( f(x) \leq'_i f(y) \);
2. \( f(x) \leq'_i f(y) \) only if there is \( z \in f^{-1}(y) \) such that \( x \leq_i z \).

In the special case where \( \nu \in \{ bsi, ten \} \), we must, in addition, require that the above conditions hold for the converses of \( \leq, \leq' \).

We now describe how to interpret \( \nu \)-rule systems over \( \nu \)-spaces. Let \( \mathfrak{X} \) be a \( \nu \)-space. If \( \nu \in \{ si, bsi, msi \} \), a \( \nu \)-valuation on \( \mathfrak{X} \) is a mapping \( V : \text{Frm}_\nu \to \text{Clop}_{\leq}(\mathfrak{X}) \) that commutes with the connectives in \( \nu \) in the usual way. On the other hand, if \( \nu \in \{ md, ten \} \), a \( \nu \)-valuation on \( \mathfrak{X} \) is defined in a similar way, except that we require \( V \) to range over \( \text{Clop}(\mathfrak{X}) \) instead of \( \text{Clop}_{\leq}(\mathfrak{X}) \). We list below how valuations commute with the most important connectives.

\[
\begin{align*}
(9) \quad V(\varphi \to \psi) &= \downarrow \leq (V(\varphi) \setminus V(\psi)), \\
(10) \quad V(\varphi \leftrightarrow \psi) &= \uparrow \leq (V(\varphi) \setminus V(\psi)), \\
(11) \quad V(\Box \varphi) &= \{ x \in X : \uparrow \leq x \subseteq V(\varphi) \}, \\
(12) \quad V(\Diamond \varphi) &= \{ x \in X : \downarrow \geq x \subseteq V(\varphi) \}, \\
(13) \quad V(\downarrow \varphi) &= \uparrow \geq V(\varphi).
\end{align*}
\]

Here and throughout the paper, we use \( \downarrow \) and \( \setminus \) to denote, respectively, the set-theoretic relative complement and difference operations.

Let \( \mathfrak{X} \) be a \( \nu \)-space and \( V \) a valuation on it. A formula \( \varphi \) is satisfied on a model \( (\mathfrak{X}, V) \) at a point \( x \) if \( x \in V(\varphi) \). In this case we write \( \mathfrak{X}, V, x \models \varphi \), otherwise we write \( \mathfrak{X}, V, x \not\models \varphi \) and say that the model \( (\mathfrak{X}, V) \) refutes \( \varphi \) at a point \( x \). A rule \( \Gamma/\Delta \) is valid on a model \( (\mathfrak{X}, V) \) when the following holds: if \( \mathfrak{X}, V, x \not\models \gamma \) holds for each \( x \in X \) and every \( \gamma \in \Gamma \), then there is some \( \delta \in \Delta \) such that \( \mathfrak{X}, V, x \models \delta \) holds for each \( x \in X \). In this case we write \( \mathfrak{X}, V \models \Gamma/\Delta \), otherwise we write \( \mathfrak{X}, V \not\models \Gamma/\Delta \) and say that the model \( (\mathfrak{X}, V) \) refutes \( \varphi \). A rule \( \Gamma/\Delta \) is valid on a \( \nu \)-space \( \mathfrak{X} \) if it is valid on the model \( (\mathfrak{X}, V) \) for every valuation \( V \) on \( \mathfrak{X} \), otherwise \( \mathfrak{X} \not\models \Gamma/\Delta \) to mean that \( \mathfrak{X} \)
refutes $\Gamma/\Delta$. The notion of validity generalizes to classes of $\nu$-spaces, as well as to classes of rules, in the obvious way.

For each of the signatures $\nu$ we shall work with, there is a duality result connecting $\nu$-algebras to $\nu$-spaces. All these dualities are generalizations of Stone duality, which relates the category of Boolean algebras with homomorphisms to that of Stone spaces with continuous functions [28]. We list these dualities in the following theorem.

**Theorem 1.6.** The category of modal (resp. Heyting, tense, bi-Heyting, frontal Heyting) algebras with homomorphism is dually equivalent to the category of modal (resp. Esakia, tense, bi-Esakia, modalised Esakia) spaces with bounded morphisms.

In each of these cases, we write $\mathfrak{A}_+$ for the space dual to an algebra $\mathfrak{A}$ and $\mathfrak{X}^+$ for the algebra dual to a space $\mathfrak{X}$. The space $\mathfrak{A}_+$ is always an expansion of the space of prime filters of $\mathfrak{A}$. We write $\beta$ for the map, called the Stone map, which takes element $a$ and returns the set $\beta(a)$ of prime filters in that algebras that contain $a$. In the other direction, the algebra $\mathfrak{X}^+$ is constructed by taking clopen sets (if $\nu \in \{md, ten\}$) or clopen upsets (if $\nu \in \{si, bsi, msi\}$). We refer the reader to [18, 37, 19, 11] for detailed descriptions and proofs of these dualities.

1.4. **Kripke semantics.** Besides spaces, in Sections 3 and 4 we shall also work with Kripke frames. We will only use Kripke frames to interpret $si$, $bsi$, modal and tense rule systems. Thus we define a Kripke frame to be a set $\mathfrak{X} := (X, \leq)$, where $X$ is a non-empty set and $\leq$ a binary relation on $X$. An intuitionistic Kripke frame $\mathfrak{X} := (X, \leq)$, where $\leq$ is a partial order. The notions of $\nu$ bounded morphism for $\nu \in \{md, ten\}$ are defined the same way as for spaces, but omitting the requirement of continuity.

For $\nu \in \{md, ten\}$, a $\nu$-valuation on a Kripke frame $\mathfrak{X}$ is a mapping $V : Frm_{\nu} \to \wp(\mathfrak{X})$ that commutes with the connectives in $\nu$ in the usual way. For $\nu \in \{si, bsi\}$, $\nu$-valuation on an intuitionistic Kripke frame $\mathfrak{X}$ is a mapping $V : Frm_{\nu} \to \wp(\mathfrak{X})$ that commutes with the connectives in $\nu$ in the usual way, such that $\uparrow V(\varphi) = V(\varphi)$ for every $\varphi \in Frm_{\nu}$. We extend our notions of satisfaction and validity from spaces to Kripke frames in the obvious way.

We recall briefly the following duality results concerning Kripke frames, which were first proved, respectively, in [39] and [16] (see also [32]).

**Theorem 1.7.** The following categories are dually equivalent.

1. Kripke frames with modal (resp. tense) bounded morphisms and perfect modal (resp. tense) algebras with complete homomorphisms.
2. Intuitionistic Kripke frames with $si$ (resp. $bsi$) bounded morphisms and complete, completely join prime generated Heyting (resp. bi-Heyting) algebras with complete homomorphisms.

We write $\mathfrak{A}_+$ for the Kripke frame dual to an algebra $\mathfrak{A}$ and $\mathfrak{X}^+$ for the algebra dual to a Kripke frame $\mathfrak{X}$. The signature of $\mathfrak{X}^+$ will be clear from context. The Kripke frame $\mathfrak{A}_+$ is constructed by expanding the set of principal prime filters of $\mathfrak{A}$ with a binary relation, which is defined the same way as in the dualities from Theorem 1.6. The algebra $\mathfrak{X}^+$ is constructed the same way as $\mathfrak{Y}^+$ when $\mathfrak{Y}$ is a space, but taking subsets (resp. upsets) instead of clopen subsets (resp. clopen upsets).
Conventions 1.8. Before moving on, we introduce a notational convention we shall use throughout the paper to discuss related rule systems and structures while avoiding cumbersome repetitions. The convention consists in the use of parentheticals in expressions naming rule systems, mathematical structures and classes thereof. For example, we will use the expression ‘$S_4$’ to refer simultaneously to the rule systems $S_4$ and $S_4,t$. Similarly, we will use the expression ‘(bi-)Heyting algebras’ to refer simultaneously to Heyting and bi-Heyting algebras.

We use these parentheticals in the same way parentheticals of the form “(resp. ...)” are normally used. To illustrate, Item 2 in Theorem 1.7 can be rewritten, using the convention just introduced, in the following way:

The following categories are dually equivalent: intuitionistic Kripke frames with (b)si bounded morphisms and complete, completely join prime generated (bi-)Heyting algebras with complete homomorphisms.

1.5. Transitive structures. We close our preliminaries by reviewing some classes of transitive structures we shall encounter throughout the paper. Let us first introduce some more notational conventions. We refer to an algebra in $\text{Alg}(S)$ as an $S$-algebra. Similarly, let an $S$-space be a space in $\text{Spa}(S)$, and an $S$-frame be a Kripke frame that validates every rule in $S$—with the additional requirement that an $S$-frame be intuitionistic when $S$ is a (b)si logic.

We recall that the $K_4,(t)$-spaces can be characterized as those modal (resp. tense) spaces with a transitive relation, and that the $S_4,(t)$-spaces coincide with those $K_4,(t)$-spaces where the relation is, in addition, reflexive. We recall some well known properties of these spaces. Given a preordered set $(X,R)$, we define:

$$q_{\text{max}}(U) := \{x \in U : \text{for all } y \in U, \text{if } Rxy, \text{then } Ryx\}$$

$$\text{max}(U) := \{x \in U : \uparrow R x \subseteq \{x\}\}$$

$$q_{\text{min}}(U) := \{x \in U : \text{for all } y \in U, \text{if } Ryx, \text{then } Rxy\}$$

$$\text{min}(U) := \{x \in U : \downarrow R x \subseteq \{x\}\}$$

We omit subscripts when they can be inferred from context.

Proposition 1.9. Let $X$ be a $K_4$-space. Then the following conditions hold for every $x \in X$ and each $U \in \text{Clop}(X)$.

1. $q_{\text{max}}(U)$ is closed.
2. If $x \in U$, then either $x \in \text{max}(U)$ or there is $y \in q_{\text{max}}(U)$ such that $Rxy$.
3. When $X$ is a $S_4$-space, Item 2 can be strengthened to the following: if $x \in U$, then there is $y \in q_{\text{max}}(U)$ such that $Rxy$.
4. When $X$ is a $S_4,t$-space, Items 1 and 3 remain true if we substitute $q_{\text{max}}(U)$ for $q_{\text{min}}(U)$ and $Rxy$ for $Ryx$.

Among $S_4,(t)$-spaces, we shall pay particular attention to $\text{Grz}),(t)$-spaces. We recall some of their basic properties. Given a preordered set $(X,R)$ and $U \subseteq X$, we call an element $x \in U$ passive in $U$ when there is no $y \in X \setminus U$ such that $Rxy$ and $Ryz$ for some $z \in U$. In other words, $x$ is passive in $U$ when one cannot “leave” and “re-enter” $U$ starting from $x$. A cluster in $(X,R)$ is a set $C \subseteq X$ which is maximal with the property that $Rxy$ and $Ryx$ whenever $x,y \in C$. A set $U \subseteq X$ is said to cut a cluster $C \subseteq X$ when neither $C \subseteq U$ nor $C \cap U = \emptyset$ hold.
Theorem 1.10 ([22, Thm. 3.5.5]). Let $\mathcal{X}$ be a S4(t)-space. Then $\mathcal{X}$ is a Grz(t)-space if and only if for every $U \in \text{Clop}(\mathcal{X})$ and any $x \in U$, there is a $y \in U$ such that $R_{xy}$ and $y$ is passive in $U$.

Corollary 1.11 ([22, Thm. 3.5.6]). Let $\mathcal{X}$ be a Grz-space and $U \in \text{Clop}(\mathcal{X})$. The following conditions hold:

1. $q_{\text{max}}(U) = \text{max}(U)$.
2. $\text{max}(U)$ does not cut any cluster.

Moreover, if $\mathcal{X}$ is also a Grz.t-space, the conditions above continue to hold when we substitute $q_{\text{min}}(U)$ for $q_{\text{max}}(U)$ and $\text{min}(U)$ for $\text{max}(U)$.

Corollary 1.12 ([22, Thm. 3.5.8]). Let $\mathcal{X}$ be a S4(t)-space. If $\mathcal{X}$ is partially ordered, then $\mathcal{X}$ is a Grz(t)-space.

We mention another simple fact concerning clusters which we shall appeal to several times.

Proposition 1.13. Let $\mathcal{X}, \mathcal{Y}$ be S4(t)-space or Kripke frames and let $f : \mathcal{X} \to \mathcal{Y}$ be an order-preserving map. Then $f^{-1}(U)$ does not cut clusters for any $U \subseteq Y$.

Another class of K4 spaces we shall pay close attention to is the class of GL-spaces. These spaces display various similarities with Grz-spaces, as the reader can appreciate by comparing the following results with Proposition 1.9, theorem 1.10, and corollary 1.11.

Theorem 1.14. Let $\mathcal{X}$ be a GL-space. Then $\mathcal{X}$ is a GL-space if and only if for every $U \in \text{Clop}(\mathcal{X})$ and any $x \in X$, if $\uparrow x \cap U \neq \emptyset$, then there is some $y \in U$ such that $R_{xy}$ and $\uparrow y \cap U = \emptyset$.

Corollary 1.15. Let $\mathcal{X}$ be a GL-space and $U \in \text{Clop}(\mathcal{X})$. The following conditions hold:

1. $\text{max}(U) = \{ x \in U : \uparrow x \cap U = \emptyset \}$;
2. $\text{max}(U) \in \text{Clop}(\mathcal{X})$;
3. If $x \in U$, then either $x \in \text{max}(U)$ or there is $y \in \text{max}(U)$ such that $R_{xy}$.

Corollary 1.16. Let $\mathcal{X}$ be a K4-space. If $\mathcal{X}$ has an irreflexive relation, then $\mathcal{X}$ is a GL-space.

2. Mappings and Translations

The main results discussed in this paper all involve translations between rules in different signatures, and semantic transformations corresponding to them. The purpose of this section is to introduce these translations and transformations.

Convention 2.1. To treat these mappings uniformly, we introduce some notational conventions to refer to the three pairs of signatures which we want to connect via translations. We let the numerals 1, 2 and 3 denote, respectively, the pairs of signatures (si, mod), (bsi, ten) and (msi, mod). When $s$ is any of these pairs of signatures, the signature occurring in the first coordinate of $s$ is called the intuitionistic signature, whereas the signature occurring in the second coordinate of $s$ is called the classical signature.
For each pair of signatures $s \in \{1, 2, 3\}$ we will define a translation function $T_s$, as well as algebraic, topological and syntactic versions of three mappings, $\sigma_s, \tau_s$ and $\rho_s$. In the case of signature pairs 1 and 2 we will also define versions of the maps $\sigma_s$ and $\rho_s$ on Kripke frames. We will adopt the further convention of suppressing subscripts for signature pairs when they can be inferred from context.

We defined distinguished rule systems and universal classes of algebras for each pair of signatures $s \in \{1, 2, 3\}$, as follows:

\begin{align*}
(14) & \quad \mathcal{I}_s := \begin{cases} 
\text{IPC} & \text{if } s = 1 \\
\text{biIPC} & \text{if } s = 2 \\
\text{KM} & \text{if } s = 3
\end{cases} \quad \mathcal{C}_s := \begin{cases} 
\text{S4} & \text{if } s = 1 \\
\text{S4.t} & \text{if } s = 2 \\
\text{K4} & \text{if } s = 3
\end{cases} \quad \mathcal{C}_s^+ := \begin{cases} 
\text{Grz} & \text{if } s = 1 \\
\text{Grz.t} & \text{if } s = 2 \\
\text{GL} & \text{if } s = 3
\end{cases}
\end{align*}

\begin{align*}
(15) & \quad \mathcal{I}_s := \text{Alg}(\mathcal{I}_s) \quad \mathcal{C}_s := \text{Alg}(\mathcal{C}_s) \quad \mathcal{C}_s^+ := \text{Alg}(\mathcal{C}_s^+)
\end{align*}

We shall use this notation to state definitions and results concerning the mappings mentioned above in a uniform fashion.

2.1. Mappings on Algebras. We begin by reviewing some well-known semantic transformations between algebras. If $\mathcal{H}$ is a Heyting algebra, the algebra $\sigma_1 \mathcal{H}$ is constructing by expanding the free Boolean extension $B(\mathcal{H})$ of $\mathcal{H}$ with the operation

$$\square a := \bigvee \{ b \in H : b \leq a \}.$$ 

If $\mathfrak{M}$ is a bi-Heyting algebra, we define $\sigma_2 \mathfrak{M}$ the same way but also add the operation

$$\Diamond a := \bigwedge \{ b \in H : a \leq b \}.$$ 

Finally, if $\mathfrak{M}$ is a frontal Heyting algebra, we define $\sigma_3 \mathfrak{M}$ by expanding $B(\mathcal{H})$ with the operation

$$\square a := \Box I a,$$

where

$$I a := \bigvee \{ b \in H : b \leq a \}.$$ 

It is known that $\sigma(\mathcal{H})$ is an $\text{Grz}(.t)$-algebra whenever $\mathcal{H}$ is a (bi-)Heyting algebra, and moreover that $\sigma_3(\mathcal{H})$ is a $\text{GL}$-algebra whenever $\mathcal{H}$ is a frontal Heyting algebra.

Conversely, if $\mathfrak{M}$ is an $\text{S4}$-algebra, the algebra $\rho_1 \mathfrak{M}$ is constructed as follows. As the carrier we take the bounded lattice $O(\mathfrak{M})$ of open elements of $\mathfrak{M}$, that is, of those elements $a \in M$ with $\square a = a$, or, equivalently, $\Diamond a = a$. We expand this lattice with the operation

$$a \rightarrow b := \square (\neg a \lor b).$$ 

When $\mathfrak{M}$ is an $\text{S4.t}$-algebra, we define $\rho_2 \mathfrak{M}$ the same way but also add the operation

$$a \leftarrow b := \Diamond (a \land \neg b).$$ 

Likewise, if $\mathfrak{M}$ is a $\text{K4}$-algebra, the algebra $\rho_3 \mathfrak{M}$ is constructed as follows. As the carrier we take the bounded lattice $O^+(\mathfrak{M})$ of quasi-open elements of $\mathfrak{M}$, i.e., those elements of $\mathfrak{M}$ with $\square^+ a = a$, where $\square^+ a := \square a \land a$. We then expand this lattice with the following operations:

$$a \rightarrow b := \square^+ (\neg a \lor b)$$

$$\Box a := \square a.$$

It is well known that $\rho_3 \mathfrak{M}$ is a (bi-)Heyting algebra for every $\text{S4}(.t)$-algebra $\mathfrak{M}$, and that $\rho_3 \mathfrak{M}$ is a frontal Heyting algebra for every $\text{K4}$-algebra $\mathfrak{M}$. 

All these mappings can be lifted to universal classes. Given $s \in \{1, 2, 3\}$, let $\mathcal{U}, \mathcal{V}$ be universal classes of algebras on which, respectively, $\sigma_s$ and $\rho_s$ are defined. We then put

$$
\sigma_s \mathcal{U} := \text{Uni}(\sigma_s \mathcal{S} : \mathcal{S} \in \mathcal{U}) \quad \rho_s \mathcal{V} := \{ \mathcal{A} : \mathcal{A} \in \mathcal{V} \}.
$$

We also introduce mappings $\tau_s : \text{Uni}(\mathcal{I}_s) \to \text{Uni}(\mathcal{C}_s)$ by setting

$$
\tau_s \mathcal{W} := \{ \mathcal{M} \in \mathcal{C} : \rho_s \mathcal{M} \in \mathcal{W} \}.
$$

2.2. Mappings on Spaces. We now describe the maps defined in the previous subsection dually. If $\mathcal{X}$ is an Esakia space, we set

$$
\sigma_1 \mathcal{X} := (X, R, \mathcal{O}) \quad \quad R := \leq.
$$

When $\mathcal{X}$ is a bi-Esakia space we let $\sigma_2 \mathcal{X} := \sigma_1 \mathcal{X}$. Thus $\sigma_1$ and $\sigma_2$ are just identity maps; we simply notate the relation differently to indicate that we are viewing the structure as a modal or tense space. Moreover, if $\mathcal{X}$ is a modalized Esakia space, we let $\sigma_3 \mathcal{X}$ be the $\leq$-free reduct of $\mathcal{X}$. By Corollary 1.12, if $\mathcal{X}$ is a (bi-)Esakia space, then $\sigma_3 \mathcal{X}$ is always a Grz$(\mathcal{t})$-space. Likewise, by Corollary 1.16, $\sigma_3 \mathcal{X}$ is always a $\mathcal{GL}$-space whenever $\mathcal{X}$ is a modalized Esakia space.

Conversely, let $\mathcal{Y}_1 := (Y, R, \mathcal{O})$ be a K4-space. For $x, y \in Y$ write $x \sim y$ iff $Rxy$ and $Ryx$. Define a map $\varphi : Y \to \varphi(Y)$ by setting $\varphi(x) = \{ y \in Y : x \sim y \}$. We call this map the skeleton map. When $\mathcal{Y}$ is an S4-space we let $\rho_1 \mathcal{Y} := (\varphi(Y), \leq, \varphi(\mathcal{O}))$ where $\varphi(x) \leq \varphi(y)$ iff $Rxy$. We let $\rho_2$ be the restriction of $\rho_1$ to S4, t spaces. When $\mathcal{Y}$ is a K4-space we let $\rho_3 \mathcal{Y} := (\varphi(Y), \leq, \varphi(\mathcal{O}))$, where $\varphi(x) \leq \varphi(y)$ iff $Rxy$ and $\rho(x) \leq \varphi(y)$ iff $Rxy$. Here $R^+$ denotes the reflexive closure of $R$.

In other words, when $\mathcal{Y}$ is a S4-space, the space $\rho_1 \mathcal{Y}$ is obtained by collapsing the clusters of $\mathcal{Y}$, lifting the relation $R$ clusterwise and endowing the result with the quotient topology under the mapping $\varphi$. When $\mathcal{Y}$ is a K4-space, $\rho_3 \mathcal{Y}$ is constructed in a similar way, except that the intuitionistic relation of $\rho_3 \mathcal{Y}$ is obtained by lifting the reflexive closure of $R$ clusterwise, and the modal relation is obtained by lifting $R$ itself clusterwise.

We note a simple property of the transformations $\rho_s$, which we shall appeal to later on.

**Proposition 2.2.** Let $\mathcal{X}$ be a K4-space. If $U \subseteq X$ is open (resp. closed), then $\varphi(U)$ is open (resp. closed) in $\rho_3 \mathcal{X}$. Moreover, the same holds when $\mathcal{X}$ is an S4-space and $\rho_3$ is replaced with $\rho_1$.

Routine arguments show that the transformations just defined are indeed dual to their algebraic counterparts defined in the previous subsection. This is to say that given $s \in \{1, 2, 3\}$, for any algebras $\mathcal{S}, \mathcal{M}$ on which the algebraic maps $\sigma_s, \rho_s$ are defined we have $(\sigma_s \mathcal{S})^* = \sigma_s \mathcal{S}^*$ and $(\rho_s \mathcal{M})^* = \rho_s \mathcal{M}^*$. Consequently, for any spaces $\mathcal{X}, \mathcal{Y}$ on which the geometric maps $\sigma_s, \rho_s$ are defined we have $(\sigma_s \mathcal{X})^* = \sigma_s \mathcal{X}^*$ and $(\rho_s \mathcal{Y})^* = \rho_s \mathcal{Y}^*$.

By appealing to these dualities, the following Proposition easily follows.

**Proposition 2.3.** Given $s \in \{1, 2, 3\}$, let $\mathcal{S} \in \mathcal{I}_s$ and $\mathcal{M} \in \mathcal{C}_s$. Then $\mathcal{S} \cong \rho_s \sigma_s \mathcal{S}$ and $\sigma_s \rho_s \mathcal{M}$ is (isomorphic to) a subalgebra of $\mathcal{M}$.
2.3. Mappings on Kripke Frames. For $s \in \{1, 2\}$, we also define versions of the maps $\sigma_s, \rho_s$ on Kripke frames. When $\mathcal{X}$ is an intuitionistic Kripke frame, we let $\sigma_2 \mathcal{X} = \mathcal{X}$. Conversely, if $\mathcal{X}$ is a Kripke frame with a reflexive and transitive relation, we let $\rho_3 \mathcal{X}$ be defined as we did above for spaces, but omitting the conditions concerning topology. Since the maps are defined the same way for the two pairs of signatures 1 and 2, we will always omit signature subscripts when working with Kripke frames. We do not define counterparts of the maps $\sigma_3, \rho_3$ on Kripke frames.

The $\rho$ transformation on Kripke frames corresponds quite closely with its topological version. In particular, for every Kripke frame $\mathfrak{F}$ on which the mapping $\rho$ is defined we have $(\rho \mathfrak{F})^+ \cong \rho \mathfrak{F}^+$, and so for every perfect $\mathcal{S}_4(t)$-algebra $\mathfrak{M}$ we have $(\rho \mathfrak{M})_+ \cong \rho \mathfrak{M}_+$. On the other hand, the algebraic version of the map $\sigma$ fails to preserve atomicity [45, p. 103], so in general the identity $(\sigma \mathfrak{F})^+ \cong \sigma \mathfrak{F}^+$ may fail. Observe further that when $\mathfrak{F}$ is an intuitionistic Kripke frame, $\sigma \mathfrak{F}$ is not guaranteed to be a Kripke frame for $\mathcal{G} \mathcal{R} \mathcal{Z}(\tau)$. As is well known, the Kripke frames for $\mathcal{G} \mathcal{R} \mathcal{Z}(\tau)$ are precisely those partially ordered Kripke frames which are conversely well founded (resp. well-founded and conversely well founded). However, intuitionistic Kripke frames need not be well founded nor conversely well founded.

2.4. Translations. All the mappings we have introduced are semantic counterparts to various translations between formulas in different signatures. These translations are all versions of the Gödel Translation [24]. For present purposes, we shall define the Gödel translation as a mapping $T_1 : \text{Frm}_{si} \to \text{Frm}_{md}$ defined recursively as follows.

$$
T_1(\bot) := \bot \\
T_1(\top) := \top \\
T_1(p) := \Box p \\
T_1(\varphi \lor \psi) := T_1(\varphi) \lor T_1(\psi) \\
T_1(\varphi \land \psi) := T_1(\varphi) \land T_1(\psi) \\
T_1(\varphi \rightarrow \psi) := \Box (\neg T_1(\varphi) \lor T_1(\psi))
$$

We extend this translation to define two more mappings, $T_2 : \text{Frm}_{bsi} \to \text{Frm}_{ten}$ and $T_3 : \text{Frm}_{msi} \to \text{Frm}_{md}$. These mappings are obtained by extending the definition above with one of the following additional conditions [cf. 41, 30]:

$$
T_2(\varphi \leftarrow \psi) := \Diamond (T_2(\varphi) \land \neg T_2(\psi)) \\
T_3(\Box \varphi) := \Box T_3(\varphi)
$$

$T_2$ was introduced in [41], whereas $T_3$ is equivalent to the translation introduced in [30] (see also [44, 43]). We extend these mappings from formulae to rules by setting $T_s(\Gamma/\Delta) := T_s[\Gamma]/T_s[\Delta]$.

We will refer to all of these mappings as “Gödel Translations.”

The interactions between the Gödel translations and the semantic mappings previously introduced are described in the next Lemma.

Lemma 2.4 (cf. [27, Lemma 3.13]). Let $s \in \{1, 2, 3\}$ and let $\mathfrak{M}$ be an algebra on which $\rho_s$ is defined. Then for every rule in the intuitionistic signature of $s$, we have

$$
\mathfrak{M} \models T_s(\Gamma/\Delta) \iff \rho_s \mathfrak{M} \models \Gamma/\Delta.
$$

Let us now define mappings between logics in different signature by means of the Gödel translations. For $s \in \{1, 2, 3\}$, let $L \in \text{Ext}(I_s)$. We define:

$$
\tau_s L := C_s \oplus \{ T_s(\Gamma/\Delta) : \Gamma/\Delta \in L \} \\
\sigma_s L := C^+_s \oplus \tau_s L.
$$
Conversely, if $\mathcal{M} \in \mathbf{NExt}(C_s)$, we put

$$\rho_s\mathcal{M} := I_s \oplus \{\Gamma/\Delta : T(\Gamma/\Delta) \in \mathcal{M}\}.$$ 

Finally, let $L \in \mathbf{Ext}(I_s)$ and $M \in \mathbf{NExt}(M_s)$. We say that $\mathcal{M}$ is a companion of $L$ when $\rho_s\mathcal{M} = L$. We call the companions of $si$ and $msi$ rule systems modal companions, and the companions of $bsi$ rule systems tense companions.

3. Stable Canonical Rules

In this section we introduce stable canonical rules for $si$, $bsi$, modal and tense rule systems. Essentially, stable canonical rules are syntactic devices for encoding finite filtrations. Although the results of this sections are only discussed in print for the $si$ and modal case, their generalizations to the $bsi$ and tense case are straightforward. We point the reader to [4, 5, 2, 3] and [26, Ch. 5] for more in-depth discussion.

We are not going to define stable canonical rules for $msi$ rule systems. This is because the main result we are interested in with respect to $msi$ rule systems is the Kuznetsov-Muravitsky isomorphism, which can be proved using only modal stable canonical rules. We comment on how stable canonical rules for $msi$ rule systems might be developed in Remark 3.3.

Since, in this section, we shall not deal with frontal Heyting algebras and their duals, unless otherwise specified we use the term algebra to refer to something which is either a modal, tense, Heyting and bi-Heyting algebras without specifying which. We adopt analogous conventions for the terms space, rule, rule system, and so on.

We begin by defining stable canonical rules.

**Definition 3.1.** Let $\mathcal{H}$ be a finite (bi-)Heyting algebra and let $D := (D^\triangledown)_{\triangledown \in \text{op}(\mathcal{H})}$, where $D^\triangledown \subseteq H \times H$. For every $a \in H$ introduce a fresh propositional variable $p_a$. The (si or bsi) stable canonical rule $\eta(\mathcal{H}, D)$ is defined as the rule $\Gamma/\Delta$, where

$$\Gamma = \{p_0 \leftrightarrow \bot\} \cup \{p_1 \leftrightarrow \top\} \cup \{p_a \land p_b : a, b \in H\} \cup \{p_a \lor p_b : a, b \in H\} \cup \bigcup_{\triangledown \in \text{op}(\mathcal{H})} \{p_a \land p_b : (a, b) \in D^\triangledown\} \cup \bigcup_{\triangledown \in \text{op}(\mathcal{H})} \{p_a \rightarrow p_b : (a, b) \in D^\triangledown\} \cup \bigcap_{\triangledown \in \text{op}(\mathcal{H})} \{p_a \leftrightarrow p_b : a, b \in H\}$$

$$\Delta = \{p_a : a \in H \text{ with } a \neq b\}.$$ 

**Definition 3.2.** Let $\mathcal{A}$ be a finite modal (resp. tense) algebra and let $D := (D^\triangledown)_{\triangledown \in \text{op}(\mathcal{A})}$, where $D^\triangledown \subseteq A$. For every $a \in A$ introduce a fresh propositional variable $p_a$. The modal (resp. tense) stable canonical rule $\mu(\mathcal{A}, D)$ is defined as the rule $\Gamma/\Delta$, where

$$\Gamma = \{p_0 \leftrightarrow \bot\} \cup \{p_1 \leftrightarrow \top\} \cup \{p_a \land p_b : a, b \in A\} \cup \{p_a \lor p_b : a, b \in A\} \cup \{p_a \rightarrow p_b : a, b \in A\} \cup \{p_a \rightarrow p_a : a \in A\} \cup \bigcup_{\triangledown \in \text{op}(\mathcal{A})} \{p_a \rightarrow p_a : a \in A\} \cup \bigcup_{\triangledown \in \text{op}(\mathcal{A})} \{p_a \leftrightarrow p_a : a \in D^\triangledown\} \cup \bigcap_{\triangledown \in \text{op}(\mathcal{A})} \{p_a \leftrightarrow p_a : a \in A\}$$

$$\Delta = \{p_a : a \in A \setminus 1\}.$$
The parenthetical \( \{ (\Diamond p_a \rightarrow p_{\Box a} : a \in A) \} \), recall, indicates that the formulae \( \Diamond p_a \rightarrow p_{\Box a} \) are to be added to \( \Gamma \) only when \( M \) is a tense algebra.\(^2\)

We will use the notation \( \zeta(\mathfrak{A}, D) \) to refer to a stable canonical rule without specifying whether it is modal, tense, si or bsi.

**Remark 3.3.** To keep the paper relatively short, we decided not to include stable canonical rules for msi rule systems. We can indicate here two ways these might be developed. One straightforward approach is to simply combine modal and si stable canonical rules, requiring partial preservation of \( \mathfrak{S} \). This approach is developed in \([31]\). Another approach, pursued in \([14]\), is to introduce rules which code up a more general notion of filtration. In the msi setting, this notion of filtration is motivated by the fact that any finite distributive lattice admits a unique expansion to a \( \mathcal{K}M \)-algebra. In the modal setting, it is obtained by lifting the requirement that \( \Box \) be preserved in one direction from the definition of standard filtration. The main reason to work with this more general notion of filtration is that \( \mathcal{K}M \) and \( \mathcal{G}L \) admit filtration in this more general sense, but not in the standard sense.

Either version of stable canonical rules for msi rule systems can be used to generalize our proof of the Dummett-Lemmon conjecture, to be presented in Section 5, to the pair of signatures \( 3. \) Liao \([31]\) was able to use our technique to prove a generalized our proof of the Dummett-Lemmon conjecture, to be presented in Section 5, to the pair of signatures \( 3. \) Liao \([31]\) was able to use our technique to prove a Dummett-Lemmon conjecture for rule systems which are quite similar to what we call msi rule systems, but where the intuitionistic modality satisfies at least the axioms of \( \mathfrak{S}4 \). It does not seem, however, that anything of substance rests on the assumption of the \( T \) axiom.

If \( \mathfrak{H}, \mathfrak{K} \) are (bi-)Heyting algebras, we call a map \( h : \mathfrak{H} \rightarrow \mathfrak{K} \) *stable* when \( h \) is a bounded lattice homomorphism. Given \( \Diamond \in \{ \to, \leftarrow \} \) and \( D^\Diamond \subseteq H \times H \), we say that \( h \) satisfies the \( \Diamond \)-bounded domain condition\(^3\) (BDC\(^\Diamond \)) for \( D^\Diamond \) if

\[
h(a \Diamond b) = h(a) \Diamond h(b)
\]

for every \((a, b) \in D^\Diamond\). It is not difficult to check that every stable map \( h : \mathfrak{H} \rightarrow \mathfrak{K} \) satisfies \( h(a \to b) \leq h(a) \to h(b) \) for every \((a, b) \in H\). If \( \mathfrak{H} \in \text{biHA} \), we also have \( h(a \leftarrow b) \geq h(a) \leftarrow h(b) \) for every \((a, b) \in H\).

Similarly, if \( \mathfrak{M}, \mathfrak{N} \) are modal (resp. tense) algebras, we call a map \( h : \mathfrak{M} \rightarrow \mathfrak{N} \) *stable* when \( h \) is a Boolean algebra homomorphism which, moreover, satisfies

\[
h(\Box a) \leq \Box h(a) \quad (\Diamond h(a) \leq h(\Diamond a))
\]

for each \( a \in A \). Given \( \Diamond \in \{ \square, \Diamond \} \) and \( D^\Diamond \subseteq A \), we say that \( h \) satisfies the \( \Diamond \)-bounded domain condition (BDC\(^\Diamond \)) for \( D^\Diamond \) if

\[
h(\Diamond a) = \Diamond h(a)
\]

\(^2\)Had we taken \( \boldsymbol{\Box} \) instead of \( \Diamond \) as primitive, we could have given a less disjunctive definition of a tense stable canonical rule. However, the present definition affords a simpler method for transforming tense stable canonical rules based on \( \mathfrak{S}4 \)-algebras into corresponding bsi stable canonical rules.

\(^3\)The BDC\(^\Diamond \) was originally called *closed domain condition* in, e.g., \([4, 2]\), following Zakharyaschev’s terminology for a similar notion in the theory of his canonical formulae. The name *stable domain condition* was later used in \([3]\) to stress the difference with Zakharyaschev’s notion. However, this choice may create confusion between the BDC and the property of being a stable map. The terminology used in this paper is meant to avoid this, while concurrently highlighting the similarity between the geometric version of the BDC, to be presented in a few paragraphs, and the definition of a bounded morphism.
for each $a \in D^\Diamond$. In both the si/bsi and the modal/tense case, we say that $h$ satisfies the BDC for $D$ if $h$ satisfies the $D^\Diamond$ for each $D^\Diamond$ in $D$.

The next result gives a uniform description of the refutation conditions of stable canonical rules on algebras in both the signatures under discussion.

**Proposition 3.4** (Cf. [2, Lemma 4.3], [4, Thm. 5.4]). For every stable canonical rule $\xi(\mathcal{A}, D)$ and every algebra $\mathcal{B}$ having the same signature as $\mathcal{A}$, we have that $\mathcal{B} \not\models \xi(\mathcal{A}, D)$ iff there is a stable embedding $h : \mathcal{B} \to \mathcal{A}$ satisfying the BDC for $D$.

**Proof sketch.** We use the identity $V(p_a) = h(a)$ to define either the desired stable embedding satisfying the BDC or the desired valuation. □

Stable canonical rules also have uniform refutation conditions on spaces and Kripke frames. If $\mathcal{X}, \mathcal{Y}$ are spaces, a map $f : \mathcal{X} \to \mathcal{Y}$ is called *stable* when it is continuous and relation preserving, in the sense that $x \leq y$ implies $f(x) \leq f(y)$ for each $x, y \in X$. If $\mathcal{X}, \mathcal{Y}$ are Kripke frames rather than spaces, we call $f : \mathcal{X} \to \mathcal{Y}$ *stable* when it is relation preserving. In either case, given $\emptyset \subseteq Y$, we say that $f$ satisfies the upward bounded domain condition (BDC$\uparrow$) for $\emptyset$ when for all $x \in X$, we have

$$\uparrow f(x) \cap \emptyset \neq \emptyset \Rightarrow f[\uparrow x] \cap \emptyset \neq \emptyset.$$  

This is to say: if there is $y \in \emptyset$ such that $f(x) \leq y$, then there must be some $z \in X$ with $x \leq z$ and $f(z) \in \emptyset$. Analogously, we say that $f$ satisfies the downward bounded domain condition (BDC$\downarrow$) for $\emptyset$ when for all $x \in X$, we have

$$\downarrow f(x) \cap \emptyset \neq \emptyset \Rightarrow f[\downarrow x] \cap \emptyset \neq \emptyset.$$  

Thus the BDC$\uparrow$ and BDC$\downarrow$ are generalizations of the defining order-theoretic conditions of a bounded morphism.

Given $\mathfrak{D}^* \subseteq \wp(Y)$ for $\ast \in \{\uparrow, \downarrow\}$, we say that $f$ satisfies the BDC$^*$ for $\mathfrak{D}^*$ when it satisfies the BDC$^*$ for each $\emptyset \in \mathfrak{D}^*$. Given a tuple $\mathfrak{D}$ with either one or two coordinates, we say that $f$ satisfies the BDC for $\mathfrak{D}$ when $f$ satisfies the BDC$\uparrow$ for the first coordinate of $\mathfrak{D}$ and the BDC$\downarrow$ for the second coordinate of $\mathfrak{D}$, if it exists. Thus the BDC$\uparrow$ is associated with the connectives $\square$ and $\to$, whereas the BDC$\downarrow$ is associated with the connectives $\Diamond$ and $\leftarrow$.

Let $\xi(\mathcal{A}, D)$ be a stable canonical rule. We define a mapping $D^\Diamond \mapsto \mathfrak{D}^\Diamond$ by putting $\mathfrak{D}^\Diamond := \{\mathfrak{D}_d^\Diamond : d \in D\}$, with

- $\mathfrak{D}_d^{\Diamond, \cup} := \beta(a) \land \beta(b)$  
- $\mathfrak{D}_d^{\square} := -\beta(a)$  
- $\mathfrak{D}_d^{\Diamond*} := \beta(a)$,

where $\beta$ is the Stone map. We then let $\mathfrak{D} := (\mathfrak{D}^\Diamond)_{\cup \in \wp(\mathcal{A})}$.

**Proposition 3.5.** For every stable canonical rule $\xi(\mathcal{A}, D)$ and for every space (resp. Kripke frame) $\mathcal{X}$, we have $\mathcal{X} \not\models \xi(\mathcal{A}, D)$ iff there is a stable surjection $f : \mathcal{X} \to \mathcal{A}_*$ satisfying the BDC for $\mathfrak{D}$.

**Proof.** The case for modal spaces is proved in [4, Thm. 3.6]; essentially the same argument can be used for the remaining cases involving spaces. In each of these cases, one appeals to the appropriate duality result from Theorem 1.6. To establish the cases involving Kripke frames, one can adapt the same argument, but replacing
appeals to duality results from Theorem 1.6 with appeals to duality results from Theorem 1.7.

Convention 3.6. In view of Proposition 3.5, we adopt the convention of writing a stable canonical rule \( \xi(\mathfrak{A}, D) \) as \( \xi(\mathfrak{A}_*, D) \) when working with spaces.

Stable maps and the BDC are closely related to the filtration construction. We recall its definition in an algebraic setting, and state the fundamental theorem used in most of its applications.

**Definition 3.7.** Let \( \mathfrak{A} \) be an algebra, \( V \) a valuation on \( \mathfrak{A} \), and \( \Theta \) a finite, subformula closed set of formulae. A (finite) model \( (\mathfrak{B}, V') \) is called a (finite) filtration of \( (\mathfrak{A}, V) \) through \( \Theta \) if the following conditions hold:

1. **Heyting and bi-Heyting case:**
   - (a) The bounded lattice reduct of \( \mathfrak{B} \) is isomorphic to the bounded sublattice of \( \mathfrak{A} \) generated by \( V[\Theta] \);
   - (b) \( V(p) = V'(p) \) for every propositional variable \( p \in \Theta \);
   - (c) The inclusion \( \subseteq: \mathfrak{B} \to \mathfrak{A} \) is a stable embedding satisfying the BDC\( ^\dove \) for the set
     \[ \{ (V'(\varphi), V'(\psi)) : \varphi \dove \psi \in \Theta \} , \]
     for each \( \dove \in op(\mathfrak{A}) \)

2. **Modal and tense case:**
   - (a) The Boolean algebra reduct of \( \mathfrak{B} \) is isomorphic to the Boolean subalgebra of \( \mathfrak{A} \) generated by \( V[\Theta] \);
   - (b) \( V(p) = V'(p) \) for every propositional variable \( p \in \Theta \);
   - (c) The inclusion \( \subseteq: \mathfrak{B} \to \mathfrak{A} \) is a stable embedding satisfying the BDC\( ^\dove \) for the set
     \[ \{ V(\varphi) : \dove \varphi \in \Theta \} , \]
     for each \( \dove \in op(\mathfrak{A}) \)

**Theorem 3.8 (Filtration theorem).** Let \( \mathfrak{A} \) be an algebra, \( V \) a valuation on \( \mathfrak{A} \), and \( \Theta \) a finite, subformula closed set of formulae. If \( (\mathfrak{B}, V') \) is a filtration of \( (\mathfrak{A}, V) \) through \( \Theta \), then for every \( \varphi \in \Theta \) we have

\[ V(\varphi) = V'(\varphi) . \]

Consequently, for every rule \( \Gamma/\Delta \) such that \( \Gamma, \Delta \subseteq \Theta \) we have

\[ \mathfrak{A}, V \vDash \Gamma/\Delta \iff \mathfrak{B}, V' \vDash \Gamma/\Delta . \]

The next result establishes that every rule is equivalent to finitely many stable canonical rules. The restriction of this lemma to si and modal rules was proved in [5, Proposition 3.3], [4, Thm. 5.5].

**Lemma 3.9 (Cf. [5, Proposition 3.3], [4, Thm. 5.5]).** The following conditions hold:

1. For every si (resp. bsi, modal, tense) rule \( \Gamma/\Delta \) there is a finite set \( \Xi \) of si (resp. bsi, modal, tense) stable canonical rules such that for any Heyting (resp. bi-Heyting, modal, tense) algebra \( \mathfrak{R} \) we have \( \mathfrak{R} \not\vDash \Gamma/\Delta \iff \mathfrak{R} \not\vDash \xi(\mathfrak{R}, D) \) for any Heyting (resp. bi-Heyting, modal, tense) algebra \( \mathfrak{R} \) and \( \xi(\mathfrak{R}, D) \in \Xi \) such that \( \mathfrak{R} \not\vDash \xi(\mathfrak{R}, D) \).
(2) When $\Gamma/\Delta$ is a modal rule, $\Xi$ can be chosen as to consist of stable canonical rules $\mu(M,D)$ such that $M$ is an $K4$-algebra, and for every $K4$-algebra $M$ we have that $M \not\models \Gamma/\Delta$ iff there is $\mu(M,D) \in \Xi$ such that $M \not\models \mu(M,D)$.

(3) When $\Gamma/\Delta$ is a modal (resp. tense) rule, $\Xi$ can be chosen as to consist of stable canonical rules $\mu(M,D)$ such that $M$ is an $S4(\tau)$-algebra, and for every $S4(\tau)$-algebra $M$ we have that $M \not\models \Gamma/\Delta$ iff there is $\mu(M,D) \in \Xi$ such that $M \not\models \mu(M,D)$.

Proof. We spell out the proofs of the si and bsi case to illustrate the exact role of filtration in the machinery of stable canonical rules. Since bounded distributive lattices are locally finite, there are, up to isomorphism, only finitely many pairs $(\mathfrak{H},D)$ such that

- $\mathfrak{H}$ is a (bi-)Heyting algebra which is at most $k$-generated as a bounded distributive lattice, where $k = |Sfor(\Gamma/\Delta)|$;
- $D = (D^\mathfrak{H})_{\eta \in \mathfrak{H}}$ with $D^\mathfrak{H} = \{(\langle \varphi \rangle, V(\psi)) : \varphi \dashv \vdash \psi \in Sfor(\Gamma/\Delta)\}$, where $V$ is a valuation on $\mathfrak{H}$.

Let $\Xi$ be the set of all rules $\eta(\mathfrak{H},D)$ for all such pairs $(\mathfrak{H},D)$, identified up to isomorphism.

$(\Rightarrow)$ Assume $\mathfrak{K} \not\models \Gamma/\Delta$ and take a valuation $V$ on $\mathfrak{K}$ refuting $\Gamma/\Delta$. Consider the bounded distributive sublattice $\mathfrak{J}$ of $\mathfrak{K}$ generated by $V[Sfor(\Gamma/\Delta)]$. Since bounded distributive lattices are locally finite, $\mathfrak{J}$ is finite. Moreover $\mathfrak{J}$ may be viewed as a Heyting or bi-Heyting algebra by defining one or both of the following operations on $\mathfrak{J}$:

- $a \dashv b := \bigvee \{c \in J : a \land b \leq c\}$
- $a \dashv b := \bigwedge \{c \in J : a \leq b \lor c\}$.

Define a valuation $V'$ on $\mathfrak{J}$ with $V'(p) = V(p)$ if $p \in \Theta$, $V'(p)$ arbitrary otherwise. Since $\mathfrak{J}$ is a sublattice of $\mathfrak{K}$, the inclusion $\subseteq$ is a stable embedding.

- Let $\varphi \rightarrow \psi \in \Theta$. Then $V'(\varphi) \rightarrow V'(\psi) \in J$. Since $\subseteq$ is a stable embedding we have $V'(\varphi) \dashv V'(\psi) \leq V'(\varphi) \rightarrow V'(\psi)$. Conversely, by the definition of $\dashv$ we find $V'(\varphi) \dashv V'(\psi) \land V'(\varphi) \leq V'(\psi)$. By the properties of Heyting algebras it follows that $V'(\varphi) \dashv V'(\psi) \leq V'(\varphi) \rightarrow V'(\psi)$. Thus, $V'(\varphi) \dashv V'(\psi) = V'(\varphi) \rightarrow V'(\psi)$.
- By analogous reasoning, whenever $\varphi \dashv \psi \in \Theta$ we have that $V'(\varphi) \dashv V'(\psi) = V'(\varphi) \rightarrow V'(\psi)$.

We have thus shown that the model $\langle \mathfrak{J}, V' \rangle$ is a filtration of the model $\langle \mathfrak{K}, V \rangle$ through $Sfor(\Gamma/\Delta)$, which implies $\mathfrak{J}, V' \not\models \Gamma/\Delta$.

$(\Leftarrow)$ Assume that there is $\eta(\mathfrak{J},D) \in \Xi$ such that $\mathfrak{K} \not\models \eta(\mathfrak{J},D)$. Let $V$ be the valuation associated with $D$ in the sense spelled out above. Then $\mathfrak{J}, V \not\models \Gamma/\Delta$. Moreover, $\langle \mathfrak{J}, V \rangle$ is a filtration of the model $\langle \mathfrak{K}, V \rangle$, so by the filtration theorem it follows that $\mathfrak{K}, V \not\models \Gamma/\Delta$. $\Box$

The proofs of the modal and tense cases of Lemma 3.9 are analogous, appealing to the local finiteness of Boolean algebras instead of the local finiteness of bounded distributive lattices. While filtrations of models based on modal or tense algebras are not unique, they can always be constructed. Furthermore, a model based on a $K4$-algebra always has a filtration which is itself based on a $K4$-algebra, and a model based on a $S4(\tau)$-algebra always has a filtration which is itself based on a
S4(\cdot t)-algebra. These observations allow one to prove the second and third parts of Lemma 3.9 by essentially the same argument.

As a consequence of Lemma 3.9 we obtain uniform axiomatizations of si, bsi, modal and tense rule systems in terms of stable canonical rules.

**Theorem 3.10** ([Cf. 5, Proposition 3.4]). The following conditions hold:

1. Any si, bsi, modal and tense rule system is axiomatisable, over the least rule system of the same kind, by some set of stable canonical rules;
2. Every modal rule system above K4 is axiomatizable, over K4, by a set of stable canonical rules based on K4-algebras.
3. Every modal (resp. tense) rule system above S4(\cdot t) is axiomatizable, over S4(\cdot t), by a set of stable canonical rules based on S4(\cdot t)-algebras.

We close this section with a brief comparison of our stable canonical rules with Jeřábek-style Canonical Rules. Our bsi and tense stable canonical rules generalize si and modal stable canonical rules in a way that mirrors the intimate connection existing between Heyting and bi-Heyting algebras on the one hand, and modal and tense algebras on the other. Just like a bi-Heyting algebra is nothing but a Heyting algebra whose order-dual is also a Heyting algebra, so every bsi stable canonical rule is a sort of “independent fusion” between two si stable canonical rules, whose associated Heyting algebras are order-dual to one another. Similarly for the tense case.

Jeřábek-style si and modal canonical rules (like Zakharyaschev-style si and modal canonical formulae), by contrast, do not generalize as smoothly to the bsi and tense case. Algebraically, a Jeřábek-style si canonical rule may be defined as follows (cf. [1, 5]).

**Definition 3.11.** Let \( \mathfrak{H} \in \text{HA} \) be finite and let \( D \subseteq H \). The si canonical rule of \( \mathfrak{H} \) is the rule \( \zeta(\mathfrak{H},D) = \Gamma/\Delta \), where

\[
\Gamma := \{ p_0 \leftrightarrow \bot \} \cup 
\{ p_a \land p_b \leftrightarrow p_a \land p_b : a, b \in H \} \cup 
\{ p_a \rightarrow p_b \leftrightarrow p_a \rightarrow p_b : a, b \in H \} \cup 
\{ p_a \lor p_b \leftrightarrow p_a \lor p_b : (a, b) \in D \} \\
\Delta := \{ p_a \leftrightarrow p_b : a, b \in H \text{ with } a \neq b \}.
\]

Generalizing the proof of [5, Corollary 5.10], one can show that every si rule is equivalent to finitely many si canonical rules. The key ingredient in this proof is a characterization of the refutation conditions for si canonical rules: \( \zeta(\mathfrak{H},D) \) is refuted by a Heyting algebra \( \mathfrak{K} \) iff there is a \((\land, \rightarrow, 0)\)-embedding \( h : \mathfrak{H} \rightarrow \mathfrak{K} \) preserving \( \lor \) on elements from \( D \). Because \((\land, \rightarrow, 0)\)-algebras are locally finite, a result known as Diego’s theorem, one can then reason as in the proof of Lemma 3.9 to reach the desired result.

It should be clear that if one defined the bsi canonical rule \( \zeta_B(\mathfrak{H},D,D') \) by combining the rules \( \zeta(\mathfrak{H},D) \) and \( \zeta(\mathfrak{H},D') \) the same way bsi stable canonical rule combine si stable canonical rules, then \( \zeta_B(\mathfrak{H},D,D') \) would be refuted by a bi-Heyting algebra \( \mathfrak{K} \) iff there is a bi-Heyting algebra embedding \( h : \mathfrak{H} \rightarrow \mathfrak{K} \). Since the variety of bi-Heyting algebras is not locally finite, this refutation condition is clearly too strong to deliver a result to the effect that every bsi rule is equivalent to a set of bsi canonical rules. Without such a result, in turn, there is no hope of axiomatizing every rule system over biIPC by means of bsi canonical rules.
Similar remarks hold in the tense case. Bezhanishvili et al. [7] show that the proof of the fact that every modal formula is equivalent, over $S_4$, to finitely many modal Zakharyaschev-style canonical formulae of $S_4$-algebras rests on an application of Diego’s theorem [cf. 7, Main Lemma]. This has to do with how selective filtrations of $S_4$-algebras are constructed. Given a $S_4$-algebra $\mathcal{B}$ refuting a rule $\Gamma/\Delta$, a key step in constructing a finite selective filtration of $\mathcal{B}$ through $Sfor(\Gamma/\Delta)$ consists in generating a $(\land, \rightarrow, 0)$-subalgebra of $\rho\mathfrak{A}$ from a finite subset of $O(A)$. This structure is guaranteed to be finite by Diego’s theorem. On the most obvious ways of generalizing this construction to tense algebras, we would need to replace this step with one of the following:

1. Generate both a $(\land, \rightarrow, 0)$-subalgebra of $\rho\mathfrak{A}$ and a $(\lor, \leftarrow, 1)$-subalgebra of $\rho\mathfrak{A}$ from a finite subset of $O(A)$;
2. Generate a bi-Heyting subalgebra of $\rho\mathfrak{A}$ from a finite subset of $O(A)$.

On option 1, Diego’s theorem and its order dual would guarantee that both the $(\land, \rightarrow, 0)$-subalgebra of $\rho\mathfrak{A}$ and the $(\lor, \leftarrow, 1)$-subalgebra of $\rho\mathfrak{A}$ are finite. However, it is not clear how one could then combine the two subalgebras into a bi-Heyting algebra, which is required to obtain a selective filtration based on a tense algebra. On option 2, on the other hand, we would indeed obtain a bi-Heyting subalgebra of $\rho\mathfrak{A}$, but not necessarily a finite one, since bi-Heyting algebras are not locally finite.

We realize that the argument sketches just presented are far from conclusive, so we do not go as far as ruling out the possibility that Jeřábek-style bsi and tense canonical rules could somehow be developed in such a way as to be a suitable tool for developing the theory of tense companions of bsi-rule systems. What such rules would look like, and in what sense they would constitute genuine generalizations of Jeřábek’s canonical rules and Zakharyaschev’s canonical formulae are interesting questions, but one we cannot hope to adequately answer here. The point we wish to stress is that answering this sort of questions is a non-trivial matter, whereas generalizing stable canonical rules to the bsi and tense setting is a completely routine task. On our approach, exactly the same methods used in the si and modal case work equally well in the bsi and tense case.

4. Blok-Esakia Theorems and the Kuznetsov-Muravitsky Isomorphism

We now set out to develop the theory of modal and tense companions of si and bsi rule systems using the machinery of stable canonical rules just presented. For each of the three pairs of signatures 1, 2 and 3 under discussion, we prove that the companions of a rule system form an interval, and establish a Blok-Esakia like result. The original Blok-Esakia theorem and the Kuznetsov-Muravitsky isomorphism follow as corollaries.

4.1. Novel Proofs. The main problem one needs to deal with in order to prove the results just announced is showing that each syntactic mapping $\sigma_s$ is surjective on the codomain $C^+_s$ (recall we are using the notation introduced in Convention 2.1.) The novelty of our approach lies in the use of stable canonical rules to establish that result.

Our strategy is centered on the following lemma.

Lemma 4.1 (Main Lemma). Given $s \in \{1, 2, 3\}$, let $\mathfrak{M} \in C^+_s$. Then for every rule $\Gamma/\Delta$ in the classical signature of $s$ we have that $\mathfrak{M} \models \Gamma/\Delta$ iff $\sigma_s\rho_s\mathfrak{M} \models \Gamma/\Delta$. 

In each of the three cases, the ($\Rightarrow$) direction is immediate from Proposition 2.3. We give full proofs of the other direction in the cases $s = 2$ and $s = 3$. A proof of the case $s = 1$ can be derived from the proof of the case $s = 2$ by making minimal adaptations, which we shall sketch.

Proof of Case $s = 2$. We prove the dual statement that $N_i \neq \Gamma \setminus \Delta$ implies $\sigma \rho N_i \neq \Gamma \setminus \Delta$. Let $\mathfrak{X} := \mathfrak{N}_i$. In view of Theorem 3.10 it is enough to consider the case $\Gamma \setminus \Delta = \mu(\mathfrak{A}, \mathfrak{D})$, for $\mathfrak{A}$ the dual of a finite $\mathfrak{S}_4(\mathfrak{A})$-algebra. So suppose $\mathfrak{X} \neq \mu(\mathfrak{A}, \mathfrak{D})$.

By Proposition 3.5, there is a stable map $f : \mathfrak{X} \rightarrow \mathfrak{N}$ satisfying the BDC for $\mathfrak{D} := (\mathfrak{D}^\delta, \mathfrak{D}^\delta)$. We construct a stable map $g : \sigma \rho \mathfrak{X} \rightarrow \mathfrak{N}$ which satisfies the BDC for $\mathfrak{D}$.

Let $C := \{x_1, \ldots, x_n\} \subseteq F$ be some cluster and let $Z_C := f^{-1}(C)$. Since $f$ is relation-preserving, $Z_C$ does not cut clusters. Therefore, by Proposition 2.2, $\varrho[Z_C]$ is clopen, and so is $f^{-1}(x_i)$ for each $x_i \in C$. Now for each $x_i \in C$ let

$$M_i := \max_R(f^{-1}(x_i))$$

$$N_i := \min_R(f^{-1}(x_i)).$$

By Proposition 1.9 and Corollary 1.11, both $M_i, N_i$ are closed, and moreover neither cuts any cluster. Consequently, by Proposition 2.2 again, both $\varrho[M_i], \varrho[N_i]$ are closed as well.

For each $x_i \in C$ let $O_i := M_i \cup N_i$. Clearly, $O_i \cap O_j = \emptyset$ for each distinct $i, j \leq n$, and since no $O_i$ cuts any cluster this implies $\varrho[O_i] \cap \varrho[O_j]$ for each distinct $i, j \leq n$. We shall now find disjoint clopens $U_1, \ldots, U_n \in \text{Clop}(\sigma \rho \mathfrak{X})$ with $\varrho[O_i] \subseteq U_i$ and $\bigcup_i U_i = \varrho[Z_C]$. Let $k \leq n$ and assume that $U_i$ has been defined for all $i < k$. If $k = n$, put $U_n = \varrho[Z_C] \setminus (\bigcup_{i<k} U_i)$ and we are done. Otherwise set $V_k := \varrho[Z_C] \setminus (\bigcup_{i<k} U_i)$ and observe that it contains each $\varrho[O_i]$ for $k \leq i \leq n$.

By the separation properties of Stone spaces, for each $i$ with $k < i \leq n$ there is some $U_{k_i} \in \text{Clop}(\sigma \rho \mathfrak{X})$ with $\varrho[O_k] \subseteq U_{k_i}$ and $\varrho[M_i] \cap U_{k_i} = \emptyset$. Then set $U_k := \bigcap_{k_i \leq n} U_{k_i} \cap V_k$.

We can now define a map $g_C : \varrho[Z_C] \rightarrow C$

$$z \mapsto x_i \iff z \in U_i.$$ 

Clearly, $g_C$ is relation preserving. Finally, define $g : \sigma \rho \mathfrak{X} \rightarrow F$ by setting

$$g(\varrho(z)) := \begin{cases} f(z) & \text{if } f(z) \text{ does not belong to any proper cluster} \\
g_C(\varrho(z)) & \text{if } f(z) \in C \text{ for some proper cluster } C \subseteq F. \end{cases}$$

Now, $g$ is evidently relation preserving. Moreover, it is continuous because both $f$ and each $g_C$ are. Thus, $g$ is a stable map.

We must now show that $g$ satisfies the BDC for $\mathfrak{D}$. Suppose $Rg(\varrho(x))y$ and $y \in \mathfrak{d}$ for some $\mathfrak{d} \in \mathfrak{D}^\delta$. By construction, $f(x)$ belongs to the same cluster as $g(\varrho(x))$, so also $Rf(x)y$. Since $f$ satisfies the BDC$^\delta$ for $\mathfrak{D}^\delta$, there must be some $z \in X$ such that $Rxz$ and $f(z) \in \mathfrak{d}$. Since $f^{-1}(f(z)) \in \text{Clop}(\mathfrak{X})$, by Proposition 1.9 and corollary 1.11 there is $z' \in \max(f^{-1}(f(z)))$ with $Rzz'$. Then also $Rxz'$ and $f(z') \in \mathfrak{d}$. But from $z' \in \max(f^{-1}(f(z)))$ it follows that $f(z') = g(\varrho(z'))$ by construction, so we have $g(\varrho(z')) \in \mathfrak{d}$. As clearly $Rg(x)\varrho(z')$, we have shown that $g$ satisfies the BDC$^\delta$ for $\mathfrak{D}^\delta$. Analogous reasoning establishes that $g$ satisfies the BDC$^\delta$ for $\mathfrak{D}^\delta$. By Proposition 3.5 this implies $\sigma \rho \mathfrak{X} \not\models \mu(\mathfrak{A}, \mathfrak{D})$. \qed
Theorem 4.2 (Skeletal generation theorem)

Either way, there is $U \in C$ since $z$. Since $f$ we have $\kappa$. It is clear that $g$ is a stable map. We show that it satisfies the BDC for $M$. Given a cluster $C := \{x_1, \ldots, x_n\} \subseteq F$ we let $Z_C := f^{-1}(C)$. Then $Z_C$ does not cut clusters, so by Proposition 2.2, $g[Z_C]$ is clopen, and so is $f^{-1}(x_i)$ for each $x_i \in C$. For each $x_i \in C$ we let

$$M_i := \max_R(f^{-1}(x_i)).$$

By Proposition 1.9 and Corollary 1.15, each $M_i$ is clopen and does not cut any cluster. Consequently, by Proposition 2.2, each $g[M_i]$ is clopen.

Note $M_i \cap M_j = \emptyset$ holds for each distinct $i, j \leq n$, and since no $M_i$ cuts clusters we have $g[M_i] \cap g[M_j] = \emptyset$ for each distinct $i, j \leq n$. Constructing the desired partition of $g[Z_C]$ into clopen sets is now simpler. First, for $k < n$ let $U_k = g[M_k]$. Then let $U_n := g[Z_C] \setminus (U_1 \cup \cdots \cup U_n)$. Then $U_1, \ldots, U_n$ are clopen sets which partition $g[Z_C]$, such that $g[M_k] \subseteq U_k$ for each $1 \leq k \leq n$.

We define our map $g : \sigma_3 \rho_3 \mathfrak{X} \rightarrow \mathfrak{F}$ as before. First, we let

$$g_C : g[Z_C] \rightarrow C$$

$$z \mapsto x_i \iff z \in U_i.$$

Clearly, $g_C$ is relation preserving. Finally, define $g : \sigma_3 \rho_3 \mathfrak{X} \rightarrow F$ by setting

$$g(g(z)) := \begin{cases} f(z) & \text{if } f(z) \text{ belongs to no proper cluster} \\ g_C(g(z)) & \text{if } f(z) \in C \text{ for some proper cluster } C \subseteq F. \end{cases}$$

It is clear that $g$ is a stable map. We show that it satisfies the BDC for $\mathfrak{D}$.

Suppose $R\bar{g}(\bar{g}(x))y$ and $y \in \mathfrak{D}$ for some $\mathfrak{D} \in \mathfrak{D}$. If $f(x)$ belongs to no proper cluster, then $g(\bar{g}(x)) = f(x)$, so $Rf(x)z$. If $f(x)$ belongs to a proper cluster, then $g(\bar{g}(x))$ belongs to the same proper cluster, so again $Rf(x)z$. Either way, $Rf(x)z$.

Since $f$ satisfies the BDC for $\mathfrak{D}$, there must be some $x \in Z$ such that $Rxz$ and $f(z) \in \mathfrak{D}$. Now, $f^{-1}(f(z)) \in \text{Clop}(\mathfrak{X})$, so by Proposition 1.9 and Corollary 1.15, one of the following conditions hold:

1. $z \in \max(f^{-1}(f(z)))$;
2. There is $z' \in \max(f^{-1}(f(z)))$ with $Rzz'$.

Either way, there is $z' \in \max(f^{-1}(f(z)))$ such that $Rxz'$. But by construction, since $z' \in \max(f^{-1}(f(z)))$, we have $f(z') = g(\bar{g}(z'))$. Consequently, $g(\bar{g}(z')) \in \mathfrak{D}$. As clearly $R\bar{g}(\bar{g}(x))\bar{g}(z')$, we have shown that $g$ satisfies the BDC for $\mathfrak{D}$. \hfill \Box

Our main lemma has the following key consequence.

Theorem 4.2 (Skeletal generation theorem). Let $s \in \{1, 2, 3\}$. Every universal class $U \in C^+_s$ is generated by its skeletal elements, i.e., $U = \sigma_3 \rho_3 U$. 

Proof. Since \( \sigma \rho \mathbb{M} \) is a subalgebra of \( \mathbb{M} \) for each \( \mathbb{M} \in \mathcal{U} \) (Proposition 2.3), surely \( \sigma \rho \mathcal{U} \subseteq \mathcal{U} \). Conversely, suppose \( \mathcal{U} \not\supseteq \Gamma/\Delta \). Then there is \( \mathbb{M} \in \mathcal{U} \) with \( \mathbb{M} \not\in \Gamma/\Delta \). By Lemma 4.1 it follows that \( \sigma \rho \mathbb{M} \not\in \Gamma/\Delta \). This shows \( \text{ThR}(\sigma \rho \mathcal{U}) \subseteq \text{ThR}(\mathcal{U}) \), which is equivalent to \( \mathcal{U} \subseteq \sigma \rho \mathcal{U} \). Hence, indeed, \( \mathcal{U} = \sigma \rho \mathcal{U} \). \( \square \)

Remark 4.3. The restriction of Theorem 4.2 to varieties of \( \mathcal{G} \mathcal{R} \mathcal{Z} \)-algebras plays an important role in the algebraic proof of the Blok-Esakia theorem for si and modal logics given by Blok [9]. The generalization to universal classes of modal algebras is explicitly stated and proved in [38, Lemma 4.4] using a generalization of Blok’s approach, although it also follows from [27, Theorem 5.5]. Blok establishes the restricted version of Theorem 4.2 as a consequence of what is now known as the Blok lemma. The proof of the Blok lemma is notoriously involved. By contrast, our techniques afford a direct and, we believe, semantically transparent proof of Theorem 4.2.

4.2. Main results. The main results of this section follow from Theorem 4.2 by routine arguments; we review them here for completeness. We begin by establishing that the syntactic mappings \( \tau, \rho, \sigma \) commute with \( \text{Alg}(\cdot) \).

Lemma 4.4. Given \( s \in \{1,2,3\} \), let \( \mathbf{L} \in \text{Ext}(I_s) \) and let \( \mathbb{M} \in \text{NExt}(C_s) \). The following conditions hold:

\[
\begin{align*}
(16) & \quad \text{Alg}(\tau_s \mathbf{L}) = \tau_s \text{Alg}(\mathbf{L}) \\
(17) & \quad \text{Alg}(\sigma_s \mathbf{L}) = \sigma_s \text{Alg}(\mathbf{L}) \\
(18) & \quad \text{Alg}(\rho_s \mathbb{M}) = \rho_s \text{Alg}(\mathbb{M})
\end{align*}
\]

Proof. (16) For every \( \mathbb{M} \in C_s \) we have \( \mathbb{M} \in \text{Alg}(\tau \mathbf{L}) \) iff \( \mathbb{M} \models T(\Gamma/\Delta) \) for all \( \Gamma/\Delta \in \mathbf{L} \) iff \( \rho \mathbb{M} \models \Gamma/\Delta \) for all \( \Gamma/\Delta \in \mathbf{L} \) iff \( \rho \mathbb{M} \in \text{Alg}(\mathbf{L}) \) iff \( \mathbb{M} \in \tau \text{Alg}(\mathbf{L}) \).

(17) In view of Theorem 4.2 it suffices to show that \( \text{Alg}(\sigma \mathbf{L}) \) and \( \sigma \text{Alg}(\mathbf{L}) \) have the same skeletal elements. So let \( \mathbb{M} = \sigma \rho \mathbb{N} \in \sigma \text{Alg}(\mathbf{L}) \). Since \( \sigma \text{Alg}(\mathbf{L}) \) is generated by \( \{\sigma \delta : \delta \in \text{Alg}(\mathbf{L})\} \) as a universal class, by Proposition 2.3 and Lemma 2.4 we have \( \mathbb{M} \models T(\Gamma/\Delta) \) for every \( \Gamma/\Delta \in \mathbf{L} \). But then \( \mathbb{M} \in \text{Alg}(\sigma \mathbf{L}) \). Conversely, assume \( \mathbb{M} = \sigma \rho \mathbb{N} \in \sigma \text{Alg}(\mathbf{L}) \). Then \( \mathbb{M} \models T(\Gamma/\Delta) \) for every \( \Gamma/\Delta \in \mathbf{L} \). By Lemma 2.4 this is equivalent to \( \rho \mathbb{N} \in \text{Alg}(\mathbf{L}) \), therefore \( \sigma \rho \mathbb{N} = \mathbb{M} \in \sigma \text{Alg}(\mathbf{L}) \).

(18) Let \( \delta \in \rho \text{Alg}(\mathbb{M}) \). Then \( \delta = \rho \mathbb{N} \) for some \( \mathbb{N} \in \text{Alg}(\mathbb{M}) \). It follows that for every si rule \( T(\Gamma/\Delta) \in \mathbf{M} \) we have \( \mathbb{N} \models T(\Gamma/\Delta) \), and so by Lemma 2.4 in turn \( \delta \models \Gamma/\Delta \). Therefore indeed \( \delta \in \text{Alg}(\rho \mathbb{M}) \). Conversely, for all rules \( \Gamma/\Delta, \) if \( \rho \mathbb{M} \models \Gamma/\Delta \), then by Lemma 2.4 \( \text{Alg}(\mathbf{M}) \models T(\Gamma/\Delta) \), hence \( \Gamma/\Delta \in \rho \mathbf{M} \). Thus \( \text{ThR}(\rho \text{Alg}(\mathbf{M})) \subseteq \rho \mathbf{M} \), and so \( \text{Alg}(\rho \mathbf{M}) \subseteq \rho \text{Alg}(\mathbb{M}) \). \( \square \)

The result just proved leads straightforwardly to the following, purely semantic characterization of companions.

Lemma 4.5. Given \( s \in \{1,2,3\} \), let \( \mathbf{L} \in \text{Ext}(I_s) \) and let \( \mathbb{M} \in \text{NExt}(C_s) \). Then \( \mathbb{M} \) is a companion of \( \mathbf{L} \) iff \( \text{Alg}(\mathbf{L}) = \rho \text{Alg}(\mathbb{M}) \).

Proof. \((\Rightarrow)\) Assume \( \mathbb{M} \) is a companion of \( \mathbf{L} \). Then we have \( \mathbf{L} = \rho \mathbb{M} \). By Lemma 4.4 \( \text{Alg}(\mathbf{L}) = \rho \text{Alg}(\mathbb{M}) \).

\((\Leftarrow)\) Assume that \( \text{Alg}(\mathbf{L}) = \rho \text{Alg}(\mathbb{M}) \). Therefore, by Proposition 2.3, \( \delta \in \text{Alg}(\mathbf{L}) \) implies \( \sigma \delta \in \text{Alg}(\mathbb{M}) \). This implies that for every rule \( \Gamma/\Delta \), \( \delta \in \mathbf{L} \) iff \( T(\Gamma/\Delta) \in \mathbb{M} \). \( \square \)
We can now prove the main results of this section. The first result asserts that the companions of a rule system form an interval.

**Theorem 4.6 (Interval theorem).** Given \( s \in \{1, 2, 3\} \), let \( L \in \text{Ext}(I_s) \). The companions of \( L \) form an interval in \( \text{NExt}(C_s) \), where the least and greatest companions are given by \( \tau_s L \) and \( \sigma_s L \).

**Proof.** In view of Lemma 4.4 it suffices to prove that \( M \) is a companion of \( L \) if \( \sigma_{\text{Alg}}(L) \subseteq \text{Alg}(M) \subseteq \tau_{\text{Alg}}(L) \).

\((\Rightarrow)\) Assume \( M \) is a modal companion of \( L \). Then by Lemma 4.5 we have \( \text{Alg}(L) = \rho\text{Alg}(M) \), therefore it is clear that \( \text{Alg}(M) \subseteq \tau\text{Alg}(L) \). To see that \( \sigma\text{Alg}(L) \subseteq \text{Alg}(M) \) it suffices to show that every skeletal algebra in \( \sigma\text{Alg}(L) \) belongs to \( \text{Alg}(M) \). So let \( 2M \cong \sigma\rho 2M \in \sigma\text{Alg}(L) \). Then \( \rho 2M \in \text{Alg}(L) \) by Lemma 2.4, so there must be \( \mathfrak{N} \in \text{Alg}(M) \) such that \( \rho\mathfrak{N} \cong \rho 2M \). But this implies \( \sigma \rho \mathfrak{N} \cong \sigma \rho 2M \cong 2M \), and as universal classes are closed under subalgebras, by Proposition 2.3 we conclude \( 2M \in \text{Alg}(M) \).

\((\Leftarrow)\) Assume \( \sigma\text{Alg}(L) \subseteq \text{Alg}(M) \subseteq \tau\text{Alg}(L) \). It is an immediate consequence of Proposition 2.3 that \( \rho \sigma\text{Alg}(L) = \text{Alg}(L) \), which gives us \( \rho\text{Alg}(M) \supseteq \text{Alg}(L) \). But by construction \( \rho\text{Alg}(M) = \rho\tau\text{Alg}(L) \), hence \( \rho\text{Alg}(M) \subseteq \text{Alg}(L) \). Therefore, indeed, \( \rho\text{Alg}(M) = \text{Alg}(L) \), so by Lemma 4.5 we conclude that \( M \) is a modal companion of \( L \).

The second result is an analogue of the Blok-Esakia theorem. We use the qualifier “general” to indicate that the theorem applies uniformly to three different pairs of signatures.

**Theorem 4.7 (General Blok-Esakia theorem).** Let \( s \in \{1, 2, 3\} \). The mappings \( \sigma_s \) and the restriction of \( \rho \) to \( \text{NExt}(C_s^+) \) are mutually inverse complete lattice isomorphisms between \( \text{Ext}(I_s) \) and \( \text{NExt}(C_s^+) \).

**Proof.** It is enough to show that the algebraic class operators \( \sigma : \text{Uni}(I_s) \to \text{Uni}(C_s^+) \) and \( \rho : \text{Uni}(C_s^+) \to \text{Uni}(I_s) \) are complete lattice isomorphisms and mutual inverses. Both maps are evidently order preserving, and preservation of infinite joins is an easy consequence of Lemma 2.4. Let \( \mathcal{U} \in \text{Uni}(C_s^+) \). Then \( \mathcal{U} = \sigma \rho \mathcal{U} \) by Theorem 4.2, so \( \sigma \) is surjective and a left inverse of \( \rho \). Now let \( \mathcal{U} \in \text{Uni}(I_s) \). It is an immediate consequence of Proposition 2.3 that \( \rho \sigma \mathcal{U} = \mathcal{U} \). Hence \( \rho \) is surjective and a left inverse of \( \sigma \). Thus \( \sigma \) and \( \rho \) are mutual inverses, and therefore must both be bijections.

We note that Theorem 4.6 remains true when restricted to lattices of logics only. This result, in the case of pair of signatures 1, was established by Maksimova and Rybakov [33]; see also [13, Sec. 9.6]. The same holds for Theorem 4.7. Thus we obtain, as corollaries, the original Blok-Esakia theorem (case \( s = 1 \)), Wolter’s [42] generalization thereof to bsi and tense logics (case \( s = 2 \)), as well as the original Kuznetsov-Muravitsky isomorphism (case \( s = 3 \)).

**Corollary 4.8 (General Blok-Esakia theorem for logics).** Let \( s \in \{1, 2, 3\} \). The restrictions of the mappings \( \sigma_s : \text{Ext}(I_s) \to \text{NExt}(C_s^+) \) and \( \rho_s : \text{NExt}(C_s^+) \to \text{Ext}(I_s) \) to the lattices of logics \( \text{Ext}_L(I_s) \) and \( \text{NExt}_L(C_s^+) \) are complete lattice isomorphisms and mutual inverses.
Proof. By construction, $\sigma$ and $\rho$ preserve the property of being a logic, because the Gödelian translation of a single-conclusion rule is always a single-conclusion rule. Moreover, the meets in $\text{ExtL}(I_\sigma)$ and $\text{NExtL}(C^+_\sigma)$ coincide, respectively, with the meets in $\text{Ext}(I_\sigma)$ and $\text{NExt}(C^+_\sigma)$. These observations, together with Theorem 4.7, imply the desired result. \hfill \Box

5. Dummett-Lemmon Conjectures

In this last section we apply stable canonical rules to give an alternative proof of the Dummett-Lemmon conjecture for rule systems. This result states that a (b)si stable rule system is Kripke complete iff its weakest modal companion is. We recall that a rule system is called Kripke complete if it is of the form $L = \{\Gamma/\Delta : K \models \Gamma/\Delta\}$ for some class of Kripke frames $K$. We also remind the reader that we will not be discussing msi rule systems in this section.

We will need to introduce and study new operations on stable canonical rules. We first define an operation taking a (b)si stable canonical rule to a modal (resp. tense) stable canonical rule equivalent to the Gödel translation of the former.

**Definition 5.1.** Let $\eta(\delta, D)$ be a (b)si stable canonical rule. The modal (resp. tense) stable canonical rule $\mu_\circ(\delta, D)$ is defined as the rule $\mu(\sigma\delta, D_\circ)$, where $D_\circ := (D^\circ_\cap)_{\cap \in OP(\delta)}$ and

$$D_\bigcirc := \{\neg a \lor b : (a, b) \in D^\cap\} \quad D_\bigast := \{a \land \neg b : (a, b) \in D^\cap\}.$$  

We call $\mu_\circ(\delta, D)$ the modalization of $\eta(\delta, D)$. Adopting our conventions for notating stable canonical rules using spaces rather than algebras, given a (b)si stable canonical rule $\eta(\mathcal{X}, D)$, the rule $\mu_\circ(\mathcal{X}, D)$ is just the rule $\mu(\sigma\mathcal{X}, D)$.

We call a rule $\xi(\mathfrak{M}, D)$ modalized when it is the modalization of some (b)si stable canonical rule. Dually, we may characterize modalized rules as follows.

**Lemma 5.2.** A modal (resp. tense) $\mu(\mathfrak{G}, \mathcal{D})$ stable canonical rule is modalized precisely when it satisfies the following conditions:

1. $\mathfrak{G}$ is partially ordered.
2. Every $\mathfrak{d} \in \mathfrak{D}^{\bigcirc}$ is of the form $U \cap V$, where $U$ is an upset and $V$ is a downset.
3. If $\mathcal{D}^{\bigast}$ is defined, then so is every $\mathfrak{d} \in \mathcal{D}^{\bigast}$.

**Proof.** If $\mu(\mathfrak{G}, \mathcal{D})$ is modalized, then $\mathfrak{G}$ is the dual of $\sigma\delta$ for some finite (bi)Heyting algebra $\delta$, so it is partially ordered. Furthermore, every $d \in D^{\bigcirc}$ is of the form $\neg a \lor b$ for $a, b \in H$, and so $\mathfrak{d}$ is of the form $\neg \beta(\neg a \lor b) = \beta(\neg a) \cap \beta(b)$. But $\beta(a), \beta(b)$ are upsets, and the complement of an upset is a downset. By similar reasoning, we may infer Item 3.

Conversely, assume $\mu(\mathfrak{G}, \mathcal{D})$ satisfies the three conditions above. Then the dual of $\mathfrak{G}$ is clearly of the form $\sigma\delta$ for some finite (bi)Heyting algebra $\delta$. Given $\mathfrak{d} = \mathcal{U} \cap \mathcal{V} \in \mathcal{D}$, by (bi-)Esakia duality there must be $a, b \in H$ with $\mathcal{U} = \beta(a)$ and $\mathcal{V} = \beta(b)$. But then $U \cap V = \beta(\mathcal{U}) \cap \beta(b) = \beta(a) \cap \beta(b)$, and by definition $d = \neg a \lor b$. Likewise, if $\mathcal{D}^{\bigast}$ is defined and $\mathfrak{d} = \mathcal{U} \cup \mathcal{V}$ satisfies Item 3, we find that $d = a \land \neg b$ for some $a, b \in H$. \hfill \Box

We now verify that modalization indeed coincides, up to equivalence over $S4(\mathcal{L})$, with the Gödel translation.
Lemma 5.3 (Rule translation lemma). Let $\mathcal{M} \in \text{Alg(S4(t))}$. For any (b)si stable canonical rule $\eta(\mathcal{F}, D)$ we have

$$\mathcal{M} \models \mu_0(\mathcal{F}, D) \iff \mathcal{M} \models T(\eta(\mathcal{F}, D)).$$

Proof. Let $\mathcal{X} := \mathcal{M}_\ast$ and $\mathcal{F} := \mathcal{F}_\ast$. Then $\eta(\mathcal{F}, D) = \eta(\mathcal{F}, \mathcal{D})$ and $\mu_0(\mathcal{F}, D) = \mu_0(\mathcal{F}, \mathcal{D})$.

$(\Rightarrow)$ Suppose $\mathcal{X} \not\models T(\eta(\mathcal{F}, \mathcal{D}))$. Then, by Lemma 2.4, $\rho \mathcal{X} \not\models \eta(\mathcal{F}, \mathcal{D})$. Consequently, there is a stable map $f : \rho \mathcal{X} \rightarrow \mathcal{F}$ satisfying the BDC for $\mathcal{D}$. We construct a stable map $g : \mathcal{X} \rightarrow \sigma \mathcal{F}$ that also satisfies the BDC for $\mathcal{D}$. To this end, put $g(x) := f(g(x))$.

Now, $g$ is continuous because both $f$ and $g$ are. Moreover, both $f$ and $g$ are relation preserving, whence $g$ is as well. Thus $g$ is a stable map. We check that it satisfies the BDC for $\mathcal{D}$. Let $\mathcal{D} \in \mathcal{D}^\mathcal{F}$ and $x \in \mathcal{X}$. Suppose there is $y \in \mathcal{D}$ such that $Rg(x)y$. Since $f$ satisfies the BDC for $\mathcal{D}$, there must be $z \in \mathcal{X}$ such that $g(z) \in \rho \mathcal{X}$ such that $g(x) \leq g(z)$ and $f(g(z)) = g(z) \in \mathcal{D}$. Moreover, since $g$ is relation reflecting, we have $Rxz$, showing $g$ satisfies the BDC for $\mathcal{D}^\mathcal{F}$. Similarly, $g$ satisfies the BCD for $\mathcal{D}^\mathcal{F}$. Consequently, $\mathcal{X} \not\models \mu(\sigma \mathcal{F}, \mathcal{D})$.

$(\Leftarrow)$ Suppose $\mathcal{X} \not\models \mu(\sigma \mathcal{F}, \mathcal{D})$. Then there is a stable map $g : \mathcal{X} \rightarrow \sigma \mathcal{F}$ satisfying the BDC for $\mathcal{D}$. We construct a map $f : \rho \mathcal{X} \rightarrow \mathcal{F}$ satisfying the BDC for $\mathcal{D}$. To this end, let $f(g(x)) := g(x)$.

Note that $f$ is well defined. For if $x$ and $y$ belong to the same cluster, we must have both $Rf(x)f(y)$ and $Rf(y)f(y)$. But $\mathcal{F}$ lacks proper clusters, showing $f(x) = f(y)$. Moreover, $f$ is relation preserving and continuous, hence a stable map. It is relation preserving because $g$ is relation reflecting and $g$ is relation preserving. To see that it is continuous, observe that $g^{-1}(U)$ never cuts clusters for any $U \subseteq F$, then apply Proposition 2.2.

We check that $f$ satisfies the BDC for $\mathcal{D}$. Let $\mathcal{D} \in \mathcal{D}^\mathcal{F}$ and $g(x) \in \rho \mathcal{X}$. Suppose there is $y \in \mathcal{D}$ such that $Rf(x)y$. Since $g$ satisfies the BDC for $\mathcal{D}$, there must be $z \in \mathcal{X}$ such that $Rg(x)z$. Since $g$ is relation preserving, $g(x) \leq g(y)$, showing $f$ satisfies the BCD for $\mathcal{D}^\mathcal{F}$. Similarly, $f$ satisfies the BCD for $\mathcal{D}^\mathcal{F}$. Consequently, $\mathcal{X} \not\models T(\eta(\mathcal{F}, \mathcal{D}))$.

Now, consider the map $g : \mathcal{G} \rightarrow \mathcal{F}$ given by $g[x] = f(x)$. It is clearly well defined. We claim that $g$ is a stable surjection that satisfies the BDC for $\mathcal{D}$. Indeed, let $\mathcal{X} \in \mathcal{D}$ and $[x] \in Y$, and suppose that $\uparrow g[x] \cap \mathcal{D} \not\subseteq \mathcal{D}$. By $g[x] = f(x)$ and the fact that $f$ satisfies the BCD for $\mathcal{D}$, it follows that there is $y \in \mathcal{X}$ such that $Rxy$ and $g[y] = f(y) \in \mathcal{D}$, as desired. □

We now show that every rule $\mu(\mathcal{F}, \mathcal{D})$ where $\mathcal{F}$ is a $\text{Grz}(t)$-space may be equivalently rewritten as a finite conjunction of modalized stable canonical rules. First, some preliminary definitions. Let $\mathcal{X}$ be a finite $\text{Grz}$-space and let $U \subseteq X$. The chunks of $U$ are defined recursively as follows. We put $ch_1(U) := \text{pas}(U)$. Assuming $ch_i(U)$ has been defined, we put $ch_{i+1}(U) := \text{pas}(U \smallsetminus (ch_1(U) \cup \cdots \cup ch_i(U)))$ whenever the right-hand side is non-empty; we leave $ch_{i+1}(U)$ undefined otherwise. Since $\mathcal{X}$ is finite, every $U \subseteq X$ only has finitely many chunks: we let the chunk height
of $U$ be the number of chunks it has. Moreover, observe that $ch_i(U) = \text{pas}(ch_i(U))$, for each $i$ less than or equal to the chunk height of $U$.

**Lemma 5.4.** Let $\mu(M, D)$ be a stable canonical rule with $M \in \operatorname{Alg}(\text{Grz}(t))$. Then there is a finite set $\Phi$ of modalized stable canonical rules, such that an $\mathcal{S}4(t)$-algebra $M$ refutes $\mu(M, D)$ iff it refutes some $\mu(\sigma\mathcal{S}, E) \in \Phi$.

**Proof.** We prove the dual statement. To keep things simple, we only show the case of modal spaces; the case of tense spaces is an adaptation of the same argument.

Let $\mathfrak{F}$ be the dual of $M$. Observe that there are, up to isomorphism, only finitely many pairs $(\mathfrak{G}, \mathfrak{E})$ satisfying the following conditions:

1. $\mathfrak{G}$ is a finite $\text{Grz}$-space whose cardinality is at most $|F| \cdot 2^k$, where $k$ is the number of all chunks of any $d \in D$.
2. $\mathfrak{E} = \{g^{-1}(ch_i(d)) : d \in D \text{ and } i \text{ at most the chunk height of } d\}$, where $g : \mathfrak{G} \rightarrow \mathfrak{F}$ is a stable surjection satisfying the BDC for $D$.

We let $\Phi$ be the set of all rules $\mu(\mathfrak{G}, \mathfrak{E})$ for all such pairs $(\mathfrak{G}, \mathfrak{E})$.

Note that each rule $\mu(\mathfrak{G}, \mathfrak{E})$ is modalized. By definition, $\mathfrak{G}$ is partially order. Moreover, if $g^{-1}(ch_i(d)) \in \mathfrak{E}$, then

$g^{-1}(ch_i(d)) = \uparrow g^{-1}(ch_i(d)) \cap \downarrow g^{-1}(ch_i(d))$.

Indeed, if $x \in \uparrow g^{-1}(ch_i(d)) \cap \downarrow g^{-1}(ch_i(d))$, then there are $y, z \in g^{-1}(ch_i(d))$ such that $R_{xz}$ and $R_{zy}$. Since $g$ is stable, it follows that $R_{g(z)g(x)}$ and $R_{g(x)g(y)}$. But since $ch_i(d) = \text{pas}(ch_i(d))$, we must have $g(x) \in ch_i(d)$, else one could leave and re-enter $ch_i(d)$. Thus, by Lemma 5.2, each $\mu(\mathfrak{G}, \mathfrak{E})$ is modalized.

$(\Rightarrow)$ Let $X$ be a $\mathcal{S}4$-space and suppose $X \not\models \mu(\mathfrak{G}, \mathfrak{E})$ for some $\mu(\mathfrak{G}, \mathfrak{E}) \in \Phi$. Then there is a stable surjection $f : X \rightarrow \mathfrak{G}$ satisfying the BDC for $\mathfrak{E}$. Let $g : \mathfrak{G} \rightarrow \mathfrak{F}$ be the stable surjection satisfying the BDC for $D$ given by Item 2 from the definition of $\Phi$. By definition, $\mathfrak{E} = \{g^{-1}(ch_i(d)) : d \in D, i \text{ at most the chunk height of } d\}$.

Consider the map $g \circ f : X \rightarrow \mathfrak{F}$. We claim that $g \circ f$ is a stable surjection that satisfies the BDC for $D$. That $g \circ f$ is surjective follows because both $f, g$ are. Likewise, $g \circ f$ is stable because both $f, g$ are. To check the BDC, take any $x \in X$ and suppose $\uparrow g(f(x)) \cap \emptyset \neq \emptyset$ for some $d \in D$. Since $g$ satisfies the BDC for $D$, there must be some $f(y) \in \mathfrak{E}$ such that $Rf(x)f(y)$ and $g(f(y)) \in d$. Let $ch_i(d)$ be the unique chunk of $d$ such that $g(f(y)) \in ch_i(d)$. Then $f(y) \in g^{-1}(ch_i(d))$. By definition, $g^{-1}(ch_i(d)) \in \mathfrak{E}$. Since $f$ satisfies the BDC for $\mathfrak{E}$, there must be some $z \in X$ such that $R_{xz}$ and $f(z) \in g^{-1}(ch_i(d))$. In other words, $g(f(z)) \in ch_i(d) \subseteq d$. This shows that, indeed, $g \circ f$ satisfies the BDC for $D$. We may then conclude $X \not\models \mu(\mathfrak{F}, \mathfrak{D})$.

$(\Leftarrow)$ Let $X$ be a $\mathcal{S}4$-space. Assume $X \not\models \mu(\mathfrak{F}, \mathfrak{D})$. Then there is a stable surjection $f : X \rightarrow \mathfrak{F}$ that satisfies the BDC for $D$. We define an equivalence relation on $X$ as follows. We put $x \sim y$ when both

(i) $f(x) = f(y)$, and
(ii) for every $ch_i(d)$ with $d \in D$, we have

$\uparrow x \cap f^{-1}(ch_i(d)) \neq \emptyset \iff \uparrow y \cap f^{-1}(ch_i(d)) \neq \emptyset$.

In other words, $x \sim y$ holds when $x$ and $y$ have the same image under $f$, and “see” the $f$-preimages of exactly the same chunks of domains from $D$. We write $[x]$ for the equivalence class of $x$ under $\sim$. Next, we define a relation on equivalence classes of $\sim$. We put $R[x][y]$ when both
Furthermore, one direction of this equivalence remains true over $S_4$ if the same $d$ of chunks of any $\rho X$ results from equipping the quotient of $\mathcal{X}$ under $\sim$ with $R$.

Observe that, by definition, $\sim$ refines the partition whose cells are points with the same $f$-images. The cardinality of that partition is clearly $|F|$. But $\sim$ splits each cell of this partition into at most $2^k$ sub-cells, where $k$ is the total number of chunks of any $\mathfrak{d} \in \mathfrak{D}$. Consequently, the cardinality of $\mathfrak{G}$ is at most $|F| \cdot 2^k$, as required by the definition of $\Phi$.

Furthermore, we claim that $\mathfrak{G}$ is a Grz-space. Since $\mathfrak{G}$ is finite, we need only check that its relation $R$ is a partial order. $R$ is clearly reflexive and transitive. For antisymmetry, assume $R[x][y]$ and $R[y][x]$. By (iii), we have $Rf(x)f(y)$ and $Rf(y)f(x)$, which implies $f(x) = f(y)$ because $\mathfrak{G}$ is partially ordered. Moreover, by (iv), we have that $\check{\mu}y \cap f^{-1}(ch_i(\mathfrak{d})) \neq \emptyset$ holds exactly when $\check{\mu}x \cap f^{-1}(ch_i(\mathfrak{d})) \neq \emptyset$ does, for each $ch_i(\mathfrak{d})$ with $\mathfrak{d} \in \mathfrak{D}$. But then $[x], [y]$ meet conditions (i) and (ii), showing $[x] = [y]$.

Let us define a map $g : \mathfrak{G} \to \mathfrak{F}$ by putting $g[x] = f(x)$. Then $g$ is a stable surjection satisfying the BDC for $\mathfrak{D}$. Indeed, $g$ is surjective because $f$ and the quotient map both are. Moreover, the way we defined the relation of $\mathfrak{G}$ immediately implies that $g$ is relation preserving, and continuity follows from the finiteness of $\mathfrak{G}$. For the BDC, suppose $\check{\mu}g[x] \cap \mathfrak{d} \neq \emptyset$ for some $\mathfrak{d} \in \mathfrak{D}$. Then $\check{\mu}f(x) \cap \mathfrak{d} \neq \emptyset$. Since $f$ satisfies the BDC for $\mathfrak{D}$, there must be $y \in X$ with $Rxy$ and $f(y) = g[y] \in \mathfrak{d}$. Since $Rxy$ implies $R[x][y]$, this shows that $g$ satisfies the BDC for $\mathfrak{D}$.

Via $g$, we may then define, in accordance to the definition of $\Phi$,

$$\mathcal{E} = \{g^{-1}(ch_i(\mathfrak{d})) : \mathfrak{d} \in \mathfrak{D}, i \text{ at most the chunk height of } \mathfrak{d}\}.$$ 

It follows that $\mu(\mathfrak{G}, \mathcal{E}) \in \Phi$.

We show that $\mathcal{X} \not\models \mu(\mathfrak{G}, \mathcal{E})$, by showing that the quotient map $x \mapsto [x]$ is a stable surjection satisfying the BDC for $\mathcal{E}$. The quotient map is clearly relation preserving and surjective. Moreover, it is continuous, because each equivalence class under $\sim$ is definable as a finite intersection of clopens. Thus, it is a stable surjection. Let us check the BDC. Let $x \in X$ and $g^{-1}(ch_i(\mathfrak{d})) \in \mathcal{E}$, and suppose $\check{\mu}[x] \cap g^{-1}(ch_i(\mathfrak{d})) \neq \emptyset$. This means that there is $[y] \in g^{-1}(ch_i(\mathfrak{d}))$ such that $R[x][y]$. By the definition of $g$, this is to say $y \in f^{-1}(ch_i(\mathfrak{d}))$. A fortiori, $\check{\mu}y \cap f^{-1}(ch_i(\mathfrak{d})) \neq \emptyset$. By condition (iv) in the definition of $R$, we may then infer that $\check{\mu}x \cap f^{-1}(ch_i(\mathfrak{d})) \neq \emptyset$. In other words, there must be $z \in X$ with $Rxz$ and $f(z) \in ch_i(\mathfrak{d})$. But $Rxz$ implies $R[x][z]$, and $f(z) \in ch_i(\mathfrak{d})$ is equivalent to $[z] \in g^{-1}(ch_i(\mathfrak{d}))$, as desired. \hfill \Box

**Remark 5.5.** It is a straightforward consequence of the Blok-Esakia theorem and Lemma 5.3 that every modal (resp. tense) rule is equivalent over Grz($\mathfrak{L}$) to a set of modalized stable canonical rules. Indeed, given a modal rule $\Gamma/\Delta$, the modal rule system $Grz(\mathfrak{L}) \oplus \Gamma/\Delta$ must be of the form $\sigma \mathfrak{L}$, for some (b)si rule system $\mathfrak{L}$. We know that $\mathfrak{L}$ must be axiomatizable, over (b1)IPC, by a set of (b)si stable canonical rules $\Psi$. But then $\sigma \mathfrak{L} = Grz(\mathfrak{L}) \oplus \{\mu_{\mathfrak{G}}(\mathfrak{F}, D) : \eta(\mathfrak{F}, D) \in \Psi\}$ by Lemma 5.3, which is to say that $\Gamma/\Delta$ is equivalent, over Grz($\mathfrak{L}$), to $\{\mu_{\mathfrak{G}}(\mathfrak{F}, D) : \eta(\mathfrak{F}, D) \in \Psi\}$. Furthermore, one direction of this equivalence remains true over $S_4(\mathfrak{L})$. Indeed, $\rho(S4(\mathfrak{L}) \oplus \Gamma/\Delta) = \rho(Grz(\mathfrak{L}) \oplus \Gamma/\Delta)$, so by Lemma 5.3 we have $\tau\rho(S4(\mathfrak{L}) \oplus \Gamma/\Delta) = \tau\rho(Grz(\mathfrak{L}) \oplus \Gamma/\Delta)$.
$S4(t) \oplus \{ \mu_\sigma(\delta, D) : \eta(\delta, D) \in \Psi \} \subseteq S4(t) \oplus \Gamma/\Delta$. This is to say $\Gamma/\Delta$ implies each $\mu_\sigma(\delta, D)$ over $S4(t)$.

These observations do not imply Lemma 5.4: for all we have said, $\Psi$ might be infinite, and the above reasoning does not establish that both directions of the equivalence go through when restricting attention to rules based on $Grz(t)$-spaces. That being said, the observations in this remark would be enough to carry out our proof of the Dummett-Lemmon conjecture. This is the strategy followed by [31] in a generalization of our technique. We chose to rely on Lemma 5.4 because we find the construction it employs independently interesting. A similar construction can be used to establish that $Grz(t)$ admits filtration, albeit in a somewhat non-standard sense. See [14, Thm. 2.74].

The last notion we need to introduce is that of a collapsed stable canonical rule.

**Definition 5.6.** Let $\mu(\mathfrak{M}, D)$ be a stable canonical rule with $\mathfrak{M} \in Alg(S4(t))$. The collapsed stable canonical rule is defined as the rule $\mu(\sigma \rho \mathfrak{M}, \sigma \rho D)$, where $\sigma \rho D := (\sigma \rho D^\triangledown)_{\triangledown \in \text{op}(\mathfrak{M})}$ and

$$\sigma \rho D^\triangledown := \left\{ \bigwedge \{ b \in B(O(\mathfrak{M})) : a \leq b \} : a \in D^\triangledown \right\}.$$ 

To understand the intuition behind collapsed rules, it is helpful to characterize them dually. Observe that the mapping on $\mathfrak{M}$ given by

$$a \mapsto \bigwedge \{ b \in B(O(\mathfrak{M})) : a \leq b \}$$

is the algebraic dual of the cluster collapse map on $\mathfrak{M}_*$, in the sense that

$$\beta \left( \bigwedge \{ b \in B(O(\mathfrak{M})) : a \leq b \} \right) = \varrho(\beta(a)).$$

Consequently, the collapsed rule $\mu(\sigma \rho \mathfrak{M}, \sigma \rho D)$ is identical to the rule $\mu(\sigma \rho \mathfrak{M}_*, \sigma \rho \mathfrak{D})$, where $\sigma \rho \mathfrak{D}$ is obtained by setting

$$\sigma \rho \mathfrak{D}^\triangledown := \{ \varrho(\mathfrak{d}) : \mathfrak{d} \in \mathfrak{D}^\triangledown \} \quad \triangledown \in \{ \downarrow, \uparrow \}$$

$$\sigma \rho \mathfrak{D} := (\sigma \rho \mathfrak{D}^\triangledown)_{\triangledown \in \text{op}(\mathfrak{D})}.$$ 

In other words, $\mu(\sigma \rho \mathfrak{M}_*, \sigma \rho \mathfrak{D})$ is obtained from $\mu(\mathfrak{F}, \mathfrak{D})$ by collapsing all clusters in $\mathfrak{F}$ and in the sets of domains $\mathfrak{D}^{\triangledown}$ as well.

Collapsed rules obey the following refutation condition on spaces and Kripke frames.

**Lemma 5.7 (Rule Collapse Lemma).** For all $\mathfrak{X} \in Spa(S4(t))$ and any stable canonical rule $\mu(\mathfrak{F}, \mathfrak{D})$ such that $\mathfrak{F} \in Spa(S4(t))$, if $\mathfrak{X} \not\equiv \mu(\mathfrak{F}, \mathfrak{D})$, then $\sigma \rho \mathfrak{X} \not\equiv \mu(\sigma \rho \mathfrak{F}, \sigma \rho \mathfrak{D})$. Moreover, the same holds if $\mathfrak{X}$ is a reflexive and transitive Kripke frame.

**Proof.** Assume $\mathfrak{X} \not\equiv \mu(\mathfrak{F}, \mathfrak{D})$. Then there is a stable map $f : \mathfrak{X} \to \mathfrak{F}$ that satisfies the BDC for $\mathfrak{D}$. Consider the map $g : \sigma \rho \mathfrak{X} \to \sigma \rho \mathfrak{F}$ given by

$$g(\varrho(x)) = \varrho(f(x)).$$

Now $Rg(x)\varrho(y)$ implies $Rx y$, and since $f$ is relation preserving also $Rf(x)f(y)$, which implies $R\varrho(f(x))\varrho(f(y))$. So $g$ is relation preserving. Furthermore, again because $f$ is relation preserving we have that for any $U \subseteq F$, the set $f^{-1}(U)$ does not cut clusters, whence $g^{-1}(U) = \varrho(f^{-1}(\varrho^{-1}(U)))$ is clopen for any $U \subseteq \varrho[F]$, as $\rho \mathfrak{X}$ has the quotient topology. Thus, $g$ is continuous.
Let us check that \( g \) satisfies the BDC for \( \sigma \rho \mathcal{D} \). Let \( \mathfrak{d} \in \mathcal{D}^\mathfrak{d} \) and suppose that \( \uparrow g(y) \cap \mathfrak{d} \neq \emptyset \). Then there is some \( g(y) \in g[F] \) with \( Rg(f(z)) g(y) \) and \( g(y) \in \mathfrak{d} \). By construction, wlog we may assume that \( g(y) \in \mathfrak{d} \). As \( g \) is relation reflecting it follows that \( Rf(x)_y \) and so we have that \( \uparrow f(x) \cap \mathfrak{d} \neq \emptyset \). Since \( f \) satisfies the BDC\(^\mathfrak{d} \) for \( \mathcal{D} \) we conclude that \( f[\uparrow x] \cap \mathfrak{d} \neq \emptyset \). So, there is some \( z \in X \) with \( f x z \) and \( f(z) \in \mathfrak{d} \). By definition, \( g(f(z)) \in g[\mathfrak{d}] \), hence we have shown that \( g[f[\uparrow x]] \cap \mathfrak{d} \neq \emptyset \), and so \( g \) indeed satisfies the BDC\(^\mathfrak{d} \) for \( \mathcal{D}^\mathfrak{d} \). Similarly, \( g \) indeed satisfies the BDC\(^\mathfrak{g} \) for \( \mathcal{D}^\mathfrak{g} \). The case where \( \mathfrak{X} \) is a Kripke frame is analogous. \( \square \)

We are now ready to prove the Dummett-Lemmon conjecture for rule systems.

**Theorem 5.8** (Dummett-Lemmon conjecture for rule systems). A \((b)s\) rule system \( L \) is Kripke complete iff \( \tau L \) is.

**Proof.** \((\Rightarrow)\) Let \( L \) be Kripke complete. Suppose that \( \Gamma \vdash \Delta \notin \tau L \). Then there is \( \mathfrak{X} \in \text{Spa}(\tau L) \) such that \( \mathfrak{X} \not\models \Gamma \vdash \Delta \). By Lemma 3.9, we may assume, wlog, that \( \Gamma \vdash \Delta = \mu(\mathfrak{g}, \mathcal{D}) \) for \( \mathfrak{g} \) a preorder. By the Rule Collapse lemma, it follows that \( \sigma \rho \mathfrak{X} \not\models \mu(\sigma \rho \mathfrak{X}, \sigma \rho \mathcal{D}) \). Let \( \Phi \) be the set of modalized stable canonical rules whose conjunction is equivalent, over \( \mathcal{S}_4(\tau, \tau) \), to \( \mu(\sigma \rho \mathfrak{X}, \sigma \rho \mathcal{D}) \), given by Lemma 5.4. Then, by Lemma 5.4, there is a modalized stable canonical rule \( \mu(\sigma \rho \mathfrak{X}, \mathfrak{E}) \in \Phi \) such that \( \sigma \rho \mathfrak{X} \not\models \mu(\sigma \rho \mathfrak{X}, \mathfrak{E}) \). By the Rule Translation Lemma, it follows that \( \rho \mathfrak{X} \not\models \eta(\mathfrak{G}, \mathfrak{E}) \).

By Lemma 4.5 and the fact that \( \mathfrak{X} \in \text{Spa}(\tau L) \) it follows that \( \rho \mathfrak{X} \in \text{Spa}(L) \). Consequently, \( \eta(\mathfrak{G}, \mathfrak{E}) \notin L \). Since \( L \) is Kripke complete, there must be a \((b)s\) Kripke frame \( \mathfrak{Y} \) such that \( \mathfrak{Y} \not\models \eta(\mathfrak{G}, \mathfrak{E}) \). Therefore, by the Rule Translation Lemma again, \( \sigma \mathfrak{Y} \not\models \mu(\sigma \rho \mathfrak{X}, \mathfrak{E}) \). Since \( \sigma \mathfrak{Y} \) is an \( \mathcal{S}_4 \)-Kripke frame, by Lemma 5.4 and Theorem 1.7 it follows that \( \sigma \mathfrak{Y} \not\models \mu(\sigma \rho \mathfrak{X}, \sigma \rho \mathcal{D}) \). Thus, there is a stable map \( f : \sigma \mathfrak{Y} \to \sigma \rho \mathfrak{X} \) satisfying the BDC for \( \sigma \rho \mathcal{D} \).

The goal now is to construct, from \( \sigma \mathfrak{Y} \) and \( f \) respectively, a Kripke frame \( \mathfrak{Z} \) for \( \tau L \) and a stable map \( g : \mathfrak{Z} \to \mathfrak{Z} \) satisfying the BDC for \( \mathcal{D} \). We do so as follows. For each \( x \in g[F] \), enumerate \( g^{-1}(x) := \{x_1, \ldots, x_{k_x}\} \). Working in \( \sigma \mathfrak{Y} \), for each \( y \in f^{-1}(x) \), replace \( y \) with a \( k_x \)-cluster \( y_1, \ldots, y_{k_x} \), and extend the relation \( R \) clusterwise: \( R_{y_i z_j} \) iff either \( y = z \) or \( R_{y z} \). This constitutes our Kripke frame \( \mathfrak{Z} \).

Note that \( \mathfrak{Z} \models \tau L \), because \( \rho \mathfrak{Z} \models \mathfrak{Y} \) (Lemma 4.5). For convenience, we identify \( \rho \mathfrak{Z} \) and \( \mathfrak{Y} \). For every \( x \in g[F] \) define a map \( g_x : f^{-1}(x) \to g^{-1}(x) \) by setting \( g_x(y_i) = x_i (i \leq k_x) \). Finally, define \( g : \mathfrak{Z} \to \mathfrak{Z} \) by putting \( g = \bigcup_{x \in g[F]} g_x \).

The map \( g \) is evidently well defined, surjective, and relation preserving. We claim that moreover, it satisfies the BDC for \( \mathcal{D} \). To see this, let \( \mathfrak{d} \in \mathcal{D}^\mathfrak{d} \) and suppose that \( \uparrow g(y_i) \cap \mathfrak{d} \neq \emptyset \). Then there is \( x_j \in F \) with \( x_j \in \mathfrak{d} \) and \( Rg(y_i)x_j \). By construction also \( g(x_j) \in g[\mathfrak{d}] \) and \( Rf(g(y_i))g(x_j) \). As \( f \) satisfies the BDC\(^\mathfrak{d} \) for \( \sigma \rho \mathcal{D}^\mathfrak{d} \) it follows that there is some \( z \in Y \) such that \( Rg(y_i)z \) and \( f(z) \in g[\mathfrak{d}] \). We may view \( z \) as \( g(z_m) \) where \( g^{-1}(f(z)) \) has cardinality \( k \geq n \). Surely \( Rg(y_i)z_m \). Furthermore, since \( f(z) \in g[\mathfrak{d}] \) there must be some \( m \leq k \) such that \( f(z)_m = g(z_m) \in \mathfrak{d} \). By construction \( R_{z_m z_m} \) and so in turn \( R_{g(y_i)z_m} \). This establishes that \( g \) indeed satisfies the BDC\(^\mathfrak{d} \) for \( \mathcal{D}^\mathfrak{d} \). Analogous reasoning shows that \( g \) satisfies the BDC\(^\mathfrak{g} \) for \( \mathcal{D}^\mathfrak{g} \). Thus we have shown \( \mathfrak{Z} \not\models \mu(\mathfrak{g}, \mathcal{D}) \). Since \( \mathfrak{Z} \models \tau L \), it follows that \( \tau L \) is Kripke complete. \( \square \)
6. Conclusion and Further Work

This paper presented a novel approach to the study of modal companions and related notions based on stable canonical rules. We hope to have shown that our method is effective and quite uniform. With only minor adaptations to a fixed collection of techniques, we provided a unified treatment of the theories of modal and tense companions, and of the Kuznetsov-Muravitsky isomorphism. We both offered alternative proofs of classic theorems and established new results.

The techniques presented in this paper are based on a blueprint easily applicable across signatures. Stable canonical rules can be formulated for any class of algebras which admits a locally finite expandable reduct in the sense of [26, Ch. 5], and once stable canonical rules are available there is a clear recipe for adapting our strategy to the case at hand. We propose that further research be done in this direction, in particular addressing the following topics.

Firstly, there are several more general notions of a msi rule system than that we have been working on, and one could try and study the theory of modal companions of such msi rule systems using our method. Some work in this direction has already been done. [31] uses our methods to study bimodal companions of rule systems over \( \text{IPC} \otimes \text{S4} \). But there are more general settings to consider. For example, one can try replacing \( \text{S4} \) to a weaker modal logic, or consider systems in a richer signature with a primitive possibility operator. [44, 43] give a very general definition of a msi logics, subsuming the cases we just mentioned, and study the theory of their polymodal companions. We conjecture that our techniques can recover several of the main known results in this area, and generalize them to rule systems.

A second avenue for further research is the theory of modal companions of extensions of the \textit{Heyting-Lewis logic}, which expands superintuitionistic logic with a strict implication connective. Early work in this area began with de Groot et al. [15], and [31] more recently applied our methods to this setting. However, several results remain open, including whether an analogue of the Blok-Esakia theorem holds.

Acknowledgment. We are very grateful to an anonymous referee for many useful comments which led to a substantial restructuring and shortening of the paper. We are also thankful to Rodrigo Almeida, Guram Bezhanishvili, Cheng Liao, and Tommaso Moraschini for helpful comments and interesting discussions.
