before the pandemic; and 81 (81/235; 34.5%) to regularly practice TD, for first visits and follow-up (50/235 = 21.3%) or only for follow-up (31/235 = 13.2%). The approximate percentage of patients visited before the pandemic with TD was <10% for the majority of respondents, mainly visited asynchronously with a store and forward modality. The great majority of doctors (88.2%) registered an increase in the demand for TD during the pandemic.

Among those who did not practice TD before COVID-19 (n = 199/434; 45.9%), 72.9% (145/199) declared to have started to practice it during the pandemic.

The main mode of TD during the pandemic was via telephone call (67.9%) alone or in combination with a store and forward (51.1%) and live interactive modality (41.1%). Acute inflammatory conditions were the main reason for consultation (32.8%).

There was a high variability in the platforms used, with ‘informal’ platforms (Skype, Zoom, WhatsApp) being the most frequently chosen (49.0%). 39% declared to use a dedicated secure hospital platform.

We asked to those who did not use TD, which was the main reason why the majority had a scarce opinion of this modality of consultation, which was judged not to be adequate to make a diagnosis by 33.3% of responders (14/42); others prefer to visit patients face by face (31%; 13/42).

32% of doctors changed their attitudes towards TD; they started TD during the pandemic and found it effective; 47% were already convinced about its utility.

In summary, in times of COVID-19 dermatology surfs the web. As highlighted by the results of this survey, many dermatologists experienced TD for the first time because of the need of social distancing and found it effective, thus reducing the number of face to face consultation and the number of accesses to the ambulatories. The efficacy of TD was already known and accepted, but the increase in the demand for TD during COVID-19 has been considerable.

Concerns related to the coronavirus disease 2019 pandemic in adult patients with atopic dermatitis and psoriasis treated with systemic immunomodulatory therapy: a Danish questionnaire survey

Dear Editor

Patients with moderate-to-severe atopic dermatitis (AD) or psoriasis often require systemic immunomodulatory therapy. The uncertainty of the potential of these therapies to increase the risk of more serious illness due to coronavirus disease 2019 (COVID-19) may have caused anxiety and led to treatment discontinuation. Therefore, we conducted an anonymous questionnaire on concerns of COVID-19 in patients with AD or psoriasis treated with systemic immunomodulatory therapy.

Adult AD and psoriasis patients with an outpatient visit at the Department of Dermatology at Aarhus University Hospital or Gentofte Hospital, Denmark, between 2 April 2020 and 15 June 2020 were invited to participate. We assessed whether patients were concerned about becoming ill with COVID-19 due to their disease and/or their systemic immunomodulatory therapy and...
whether patients discontinued their treatment during the COVID-19 pandemic.

A total of 301 adult patients including 68 with AD and 233 with psoriasis completed the questionnaire. Of these, 35.7% were female and 24.5% were ≥60 years old (Table 1). The most common comorbidities were hay fever (69.1%) and asthma (60.3%) among AD patients, and psoriatic arthritis (32.6%) and cardiovascular diseases (18.0%) among psoriasis patients. Patients felt to a great extent well treated (67.0%) and safe about their treatment in general (76.4%).

We found that 52.7% were concerned about becoming ill with COVID-19 due to their skin disease and 68.0% due to their treatment, respectively, and 7.3% discontinued their treatment. No differences were observed for age, type of treatment or treatment duration, but female patients were more concerned about becoming ill with COVID-19 due to their treatment than male patients (Table 2). AD patients with asthma were more concerned about becoming ill with COVID-19 due to their AD and treatment, whereas psoriasis patients with psoriatic arthritis were more concerned about becoming ill due to psoriasis (Table 2). Further, patients who in general felt unsafe about their treatment were more concerned about becoming ill with COVID-19 (P < 0.01) and were more likely to discontinue their treatment during the COVID-19 pandemic (P = 0.018).

Fear of serious consequences of COVID-19 infection might lead patients to discontinue treatment without consulting a dermatologist. An Italian study found 5.2% of 515 psoriasis patients treated with biologics discontinued therapy by themselves.1 We found 7.3% patients discontinued their therapy. Interestingly, as Denmark has a low proportion of COVID-19 cases, treatment discontinuation could be driven by media-induced fear instead of COVID-19 infections. Indeed, patients who discontinued treatment felt less safe with their treatment in general, highlighting the need of identifying these patients and informing them accordingly. More than half the patients found themselves concerned about becoming ill with COVID-19 due to their disease and/or their treatment. This could be attributed to comorbidities related to increased risk for severe COVID-19 infection, e.g. asthma in AD patients and conflicting information regarding COVID-19. During the early phases of the COVID-19 pandemic, experts disagreed on how to act regarding immunomodulatory therapy.2–4 Since then, studies have not found an increased risk of serious consequences of COVID-19 infection in AD or psoriasis patients treated with immunomodulatory therapies.2–7 These therapies may even have a protective role against the cytokine storm seen in critical cases of COVID-19.8 Currently, trials for targeted immunomodulatory therapies investigating the efficacy in COVID-19 are undergoing,9 and dexamethasone has already shown promising results.10 Some limitations should be considered, e.g. the self-reported nature of the study and that only patients with an outpatient visit at the department of dermatology were included resulting in risk of selection bias. In conclusion, identifying and informing patients feeling unsafe with treatment is important as this might avoid unnecessary treatment discontinuations.

**Funding sources**

There was no funding for the study.

| Table 1 Baseline demographics |
|-----------------------------|
|                            | Patients with atopic dermatitis n = 68 | Patients with psoriasis n = 233 | All patients n = 301 |

Severe COVID-19 outcomes in patients with psoriasis

Psoriasis is a chronic inflammatory disease associated with comorbidities known to increase risk of severe COVID-19, such as hypertension, cardiovascular disease, diabetes and obesity.1,2 Use of systemic therapies may increase a patient’s risk of infections.3 Our study aims to evaluate the association of psoriasis systemic therapy and COVID outcomes.

This retrospective cohort study used RPDR, a clinical data registry, to identify patients with psoriasis (ICD-10 code L40) and positive COVID RT-PCR, between March and May/2020. By reviewing medical records on EPIC, active psoriasis prior to COVID was confirmed.

The exposure was psoriasis systemic therapy for at least three months prior to COVID. Our primary outcome was a composite of ICU admission, intubation and/or death.

†Continuous and categorical data are represented by mean ± SD and number of patients (%), respectively. Patients on both a biologic and methotrexate were not shown in the biologic and methotrexate columns, only in the combined systemic therapy column. MTX – methotrexate.

‡Comparison between patients on any systemic therapy and non-systemic therapy, using two-sided Student’s t-test, Fisher’s exact test or logistic regression for continuous and categorical data, respectively.
