We examine the evaluation of the minimum information loss due to an unread local measurement in mixed states of bipartite systems, for a general entropic form. Such a quantity provides a measure of quantum correlations, reducing for pure states to the generalized entanglement entropy, while in the case of mixed states it vanishes just for classically correlated states with respect to the measured system, as the quantum discord. General stationary conditions are provided, together with their explicit form for general two-qubit states. Closed expressions for the minimum information loss as measured by quadratic and cubic entropies are also derived for general states of two-qubit systems. As an application, we analyze the case of states with maximally mixed marginals, where a general evaluation is provided, as well as $X$ states and the mixture of two aligned states.

I. INTRODUCTION

There is currently a great interest on new measures of quantum correlations for mixed states, different from the entanglement measures [1]. Quantum entanglement is essential for quantum teleportation [2,3] and also for pure state quantum computation, where its increase with system size is necessary to achieve an exponential speedup over classical computation [4,5]. However, the computation model proposed by Knill and Laflamme [6] has shown that for mixed states, such speedup can in principle be achieved without entanglement [7]. This suggests the subsistence of useful quantum correlations in some separable mixed states, which, we recall, are defined as convex mixtures of product states [8]. While a separable pure state is a product state, separable mixed states comprise product states, mixtures of commuting products, and also mixtures of noncommuting product states. The latter can possess entangled eigenstates and give rise to nonclassical capabilities.

Consequently, measures such as the quantum discord [9–12] have recently received much attention. While coinciding with the entanglement entropy in pure states, the quantum discord can be nonzero in mixed separable states, vanishing just for full or one-way classically correlated states, i.e., states diagonal in a standard or conditional product basis. The circuit of [6] was in fact shown in [13] to exhibit a non-negligible discord. Other measures with similar properties include the one-way information deficit [14,15], the geometric discord [16], based on the standard Hilbert-Schmidt norm, and the general entropic measures which we defined in [17], based on generalized entropic forms. The latter contain the two previous measures as particular cases, embedding them in a unified picture. Since they are applicable with entropic forms complying with minimum requirements, they offer, like the geometric discord, the possibility of easier evaluations, allowing at the same time the identification of some universal features exhibited by all these measures [17]. Related generalized measures vanishing just for fully classically correlated states, like those of [18] and [19], were also considered [17]. Let us remark that important quantum capabilities of separable states with nonzero discord, and hence nonzero values of the previous measures, were recently unveiled [15,20–23]. Other relevant properties of quantum discord and its evaluation in specific states and scenarios were discussed in [24–35].

The aim of this work is to analyze the explicit evaluation of the generalized measures of [17] in some important general cases. We first provide in Sec. II the general stationary condition that the least disturbing local measurement should satisfy, including conditions for its independence from the entropy employed (universality), together with its explicit form for general two-qubit states. Here we show that in addition to the quadratic case (geometric discord), the measure based on a cubic function of the density matrix ("cubic" discord) can also be exactly evaluated for any state of two qubits. Moreover, for two-qubit states this measure shares with the geometric discord the same pure state limit, where they are both proportional to the square of the concurrence [36,37]. As specific applications, we provide in Sec. III the general expression for two-qubit states with maximally mixed reduced states, valid for any entropic form, analyzing its main features. We also examine their evaluation in the so-called $X$ states [32], where explicit expressions for the quadratic and cubic cases are provided, and for the important case of a mixture of two aligned states [33], which represents in particular the exact state of a pair in the ground state of a finite $XY$ ferromagnetic spin 1/2 chain in the vicinity of the factorizing field [38]. Differences with the quantum discord, related in particular with the minimizing measurement, are also discussed. Conclusions are finally drawn in Sec. IV.

II. FORMALISM

A. Information loss by unread local measurement

Let us consider a bipartite system $A + B$ initially in a state $\rho_{AB}$. After an unread local von Neumann measurement in system $B$, defined by orthogonal one-dimensional projectors $P^B_j = I \otimes P_j$, with $P_j = |jB\rangle\langle jB|$ ($\sum_j P_j = I$, $P_j P_j = \delta_{jj} P_j$), the joint state becomes

$$\rho_{AB} = \sum_j P^B_j \rho_{AB} P^B_j = \sum_j p_j \rho_{AB|j},$$

where $p_j = \text{Tr} \rho_{AB} P^B_j$ is the probability of outcome $j$ and $\rho_{AB|j} = P^B_j \rho_{AB} P^B_j / p_j$ the state after such outcome. The state (1) is just the diagonal of $\rho_{AB}$ in a conditional product basis formed by the states $|ij\rangle \equiv |iA\rangle|jB\rangle$, with $|iA\rangle$ the eigenstates of $\rho_{A|j} = \text{Tr}_B \rho_{AB|j}$. The loss of information due to such measurement, i.e., the information contained in the
off-diagonal elements of the original $\rho_{AB}$ in the previous basis, can be quantified by the quantity \cite{17}

$$I_f^M(\rho_{AB}) = S_f(\rho_A') - S_f(\rho_{AB}),$$

(2)

where $S_f(\rho)$ denotes a generalized entropy of the form

$$S_f(\rho) = \text{Tr} f(\rho),$$

\text{(3)}

with $f : [0,1] \to \mathbb{R}$, a smooth strictly concave function $[f''(p) < 0 \text{ for } p \in (0,1)]$ satisfying $f(0) = f(1) = 0$ \cite{39, 40}. This ensures $S_f(\rho) \geq 0$ for any state $\rho$, with $S_f(\rho) = 0$ if and only if $\rho$ is a pure state ($\rho^2 = \rho$), and $S_f(\rho)$ maximum, at fixed dimension $d$, for the maximally mixed state $\rho = 1/d$. Equation (2) is then non-negative for any $S_f$ of the previous form, vanishing only if the original $\rho_{AB}$ remains unchanged by such measurement. This positivity follows from the majorization relation \cite{3, 40, 41} $\rho_{AB} \prec \rho_{AB}$ (i.e., $\rho_{AB}$ more mixed than $\rho_{AB}$) satisfied by the post-measurement state, which implies $S_f(\rho_{AB}) \geq S_f(\rho_{AB})$ for all such $S_f$ \cite{17}. Moreover, the previous entropic inequality implies in fact majorization when valid for all $S_f$ of the previous form \cite{42}.

The minimum of $I_f^M$ among all local measurements,

$$I_f^M(\rho_{AB}) = \min_{M_B} I_f^M(\rho_{AB}),$$

\text{(4)}

provides a measure of the quantum correlations between $A$ and $B$ present in the original state and destroyed by local measurement \cite{17}. It vanishes only if $\rho_{AB}$ is already of the “classical” (with respect to $B$) form of Eq. (1). For such states there is no real local measurement in $B$ ($M_B$) which leaves the state invariant. Equation (4) is obviously not affected by local unitary transformations.

In the case of pure states ($\rho_{AB}^2 = \rho_{AB}$), it can be shown that Eq. (4) becomes the generalized entanglement entropy

$$I_f^B(\rho_{AB}) = E_f(A,B) = S_f(\rho_A) = S_f(\rho_B),$$

\text{(5)}

where $\rho_A = \text{Tr}_B \rho_{AB}$ and $\rho_B$ are the reduced states of each subsystem \cite{17}. Hence, pure state entanglement can be seen as the minimum information loss due to a local measurement. In this case $I_f^B(\rho_{AB}) = I_f^M(\rho_{AB})$, an identity which does not hold in general for mixed states.

In the von Neumann case $S_f(\rho) = S(\rho) = -\text{Tr} \rho \log \rho$, Eq. (2) can also be written as \cite{17}

$$I_f^M(\rho_{AB}) = S(\rho_A') - S(\rho_{AB}) = S(\rho_{AB} || \rho_A'),$$

(6)

where $S(\rho || \rho') = -\text{Tr} \rho \log \rho' - \text{Tr} \rho' \log \rho$ is the relative entropy \cite{39, 40} (a non-negative quantity), since $\rho_A'$ is the diagonal of $\rho_{AB}$ in a certain basis. The minimum $I_f^B$ of Eq. (6) coincides with the one-way information deficit \cite{14, 15} and also with one of the measures discussed in \cite{18}. In the case of pure states, $I_f^B$ reduces to the standard entanglement entropy $E(A,B) = S(\rho_A) = S(\rho_B)$.

In the case of the so-called linear entropy

$$S_2(\rho) = 2(1 - \text{Tr} \rho^2),$$

\text{(7)}

which is a quadratic function of $\rho$ and corresponds to $f(\rho) = 2\rho(1 - \rho)$ in Eq. (3), Eq. (2) can be written as \cite{17}

$$I_2^M(\rho_{AB}) = S_2(\rho_A') - S_2(\rho_{AB}) = 2||\rho_A' - \rho_{AB}||^2.$$

\text{(8)}

where $||O||^2 = \text{Tr} O^2$ is the squared Hilbert-Schmidt norm. The ensuing minimum of Eq. (4), to be denoted here as $I_2^B$, becomes then equivalent \cite{17} to the geometric discord of Ref. \cite{16}, defined as the minimum Hilbert-Schmidt distance between $\rho_{AB}$ and any classically correlated state of the form (1).

In the case of pure states, $I_2^B$ reduces to the square of the pure state concurrence (i.e., the tangle), $C^2_{AB} = (1 - \text{Tr} \rho_A^2)$ \cite{37}.

In the same way we may define the $q$ information loss as

$$I_q^M(\rho_{AB}) = S_q(\rho_A') - S_q(\rho_{AB}),$$

\text{(9)}

$$S_q(\rho) = (1 - \text{Tr} \rho^q)/(1 - 2^{1/q}), \quad q > 0,$$

(10)

where $S_q(\rho)$ is the so-called Tsallis entropy \cite{44}, which corresponds to $f(\rho) = (\rho - \rho^q)/(1 - 2^{1/q})$ in Eq. (3) and is a function of the Renyi entropy. Equation (10) reduces to the linear entropy of Eq. (7) for $q = 2$ and to the von Neumann entropy for $q \to 1$, with $\log \to \log_2$, for the present normalization [chosen such that $S_q(\rho) = 1$ for a maximally mixed single-qubit state, i.e., $2f(1/2) = 1$]. Equation (9) allows one, in particular, switch continuously from the von Neumann case (6) to the quadratic case (7).

On the other hand, the original quantum discord \cite{9-12} is based on the von Neumann entropy and can be written (considering von Neumann measurements) as

$$D^B(\rho_{AB}) = \min_{M_B} [I_4^M(\rho_{AB}) - I_4^M(\rho_B)].$$

\text{(11)}

It contains an additional term $I_4^M(\rho_{AB}) = S(\rho_A') - S(\rho_B)$ related to the local information loss and was actually defined in \cite{9} as the minimum difference between the initial mutual information

$$I(A:B) = S(\rho_A \otimes \rho_B) - S(\rho_{AB}),$$

(12)

where $S(\rho_A \otimes \rho_B) = S(\rho_A) + S(\rho_B)$, and that after the local measurement, $I_4^M(A:B) = S(\rho_A') + S(\rho_B') - S(\rho_{AB}').$ Since $\rho_A' = \rho_A$, such difference reduces to Eq. (11).

The information loss of Eq. (2) can be regarded in fact as a type of generalized mutual information. Equation (12) is a measure of the total correlations between $A$ and $B$ in the original state, absent in the product state $\rho_A \otimes \rho_B$. The latter is the state which maximizes the von Neumann entropy subject to the constraint of providing just all local averages $(O \otimes I)$ and $(I \otimes O)$, i.e., the correct reduced states $\rho_A$ and $\rho_B$. This is in fact what is expressed by the positivity of Eq. (12): any other state $\rho_{AB}$ with the same local reduced states has a smaller entropy.

On the other hand, the post-measurement state (1) can be seen as the more mixed state providing the same averages as $\rho_{AB}$ of all observables of the form $\sum_j \alpha_j O_j \otimes P_j$, diagonal in the local basis defined by $M_B$ as $\text{Tr} \rho_{AB} O \otimes P_j = \text{Tr} \rho_A' O \otimes P_j$, such that $S_f(\rho_{AB}') \geq S_f(\rho_{AB}') \forall S_f$. The difference $I_4^M$ then is a measure of the correlations $\langle O \otimes |j\rangle \langle k| \rangle$, $k \neq j$, contained in the original state $\rho_{AB}$ and absent in $\rho_{AB}'$. In particular, if $M_B$ is a measurement in a basis where $\rho_B$ is diagonal, $\rho_A$ reproduces not only $\rho_A$ ($\rho_A' = \text{Tr}_B \rho_{AB}' = \rho_A \neq M_B$) but also $\rho_B$ ($\rho_A' = \text{Tr}_A \rho_{AB}' = \rho_B$ for this measurement), as well as all averages $(O \otimes P_j)$, being the more mixed state with such property. Notice that in contrast to $\rho_{AB}'$, the state $\rho_A \otimes \rho_B$ is in general not more mixed than...
the original state \((\rho_A \otimes \rho_B \neq \rho_{AB})\), so that the positivity of Eq. (12) cannot be extended to a general entropy.

**B. General stationary condition**

Let us now derive the equations determining the least disturbing local measurement defined by Eq. (4).

**Theorem 1.** For a given entropic function \(f\), the least disturbing local measurement satisfies the equation

\[
\text{Tr}_A[f'(\rho_{AB}'), \rho_{AB}] = 0, \tag{13}
\]

where \(f'\) is the derivative of \(f\) and \(\rho_{AB}'\) the post-measurement state (1).

**Proof.** The generalized entropy of the state (1) is

\[
S_f(\rho_{AB}) = \sum_{i,j} f(p_{ij}^f) \cdot p_{ij}^f = \langle ij | \rho_{AB} | ij \rangle, \tag{14}
\]

where \(\langle ij | \rho_{AB} | k \rangle = \delta_{ik} p_{ij}^f\). Considering a small unitary variation of the local measurement basis, such that \(\delta |j \rangle = ((e^{\delta h} - 1) |j \rangle) \approx i \delta h |j \rangle\), with \(\delta h\) a small local Hermitian operator, we have \(\delta p_{ij} \approx \delta_{ij} \delta_{ik} \rho_{AB} [\delta h]_B |ij\rangle \) up to first order in \(\delta h\), with \(\delta \rho_B = I \otimes \delta h\). Hence,

\[
\delta I_{q}^{MS} = \sum_{i,j} f'(p_{ij}^f) \delta p_{ij}^f = i \text{Tr}_{B} [f' (\rho_{AB}') \cdot \rho_{AB}] \delta h_B = i \text{Tr}_{B} [\text{Tr}_{A} [f' (\rho_{AB}') \cdot \rho_{AB}]] \delta h.
\]

The condition \(\delta I_{q}^{MS} = 0 \forall \delta h\) leads then to Eq. (13). \(\square\)

Equation (13) implies explicitly \(\sum_{ij} f'(p_{ij}^f) |ij\rangle |\rho_{AB} |ij\rangle = \sum_{ij} f'(p_{ij}^f) (i |j\rangle |\rho_{AB} |i k\rangle \forall k, j\rangle\), and determines a certain set of feasible local bases \(|jj\rangle\). The corresponding states \(|ij\rangle\) of \(A\) depend in general on \(j\).

The minimizing basis \(|jj\rangle\) will not diagonalize, in general, the reduced state \(\rho_{AB}\). Nonetheless, the local eigenstates will be optimum in some important situations: If in a standard product basis \(|ij\rangle = |i\rangle |j\rangle\) formed by eigenstates of \(\rho_A\) and \(\rho_B\) the only off-diagonal elements of \(\rho_{AB}\) are \(|ij\rangle |\rho_{AB} |kl\rangle\) with \(i \neq k\) and \(j \neq l\), then

\[
\langle ij | \rho_{AB} | kl \rangle = \delta_{jk} p_{ij}^f, \quad \langle ij | \rho_{AB} | lj \rangle = \delta_{il} p_{ij}^f, \tag{15}
\]

then Eq. (13) will be trivially satisfied \(\forall S_f\) for a measurement in the basis \(|jj\rangle\). Such basis would then provide a universal stationary point of \(I_{q}^{MS}\). This is precisely the case of a pure state, written in the Schmidt basis as \(|\Psi_{AB}\rangle = \sum_k \sqrt{p_k} |k_A k_B\rangle\), and also of a mixture of \(|\Psi_{AB}\rangle\) with the maximally mixed state,

\[
\rho_{AB} = x |\Psi_{AB}\rangle \langle \Psi_{AB}| + \frac{1 - x}{n} I, \quad x \in [0, 1],
\]

where Eq. (15) and hence Eq. (13) will be satisfied \(\forall f\) for a measurement in the basis \(|kk\rangle\). It was shown in \cite{17} that such basis provides the universal least disturbing local measurement for these states, minimizing \(I_{q}^{MS} \forall S_f\).

In the case of the linear entropy, \(f'(\rho_{AB}) \propto I - 2 \rho_{AB}'\) and Eq. (13) becomes just \(\text{Tr}_{A} [\rho_{AB}' \cdot \rho_{AB}] = 0\), indicating that the post-measurement state \(\rho_{AB}'\) should locally (in \(B\)) commute with the original state.

In the case of the original discord of Eq. (11), the additional local term leads in the variation to the modified equation

\[
\text{Tr}_{A} [f' (\rho_{AB}' \cdot \rho_{AB}) - f' (\rho_B) \rho_B] = 0, \tag{16}
\]

where here \(f'(\rho)\) can be replaced by \(- \log \rho\).

**C. Two-qubit case**

Let us now examine in detail the case of two qubits. Any state of a two-qubit system can be written as

\[
\rho_{AB} = \frac{1}{2} (I + r_A \cdot \sigma_A + r_B \cdot \sigma_B + r_A' \cdot J \sigma_B), \tag{17}
\]

where \(\sigma_A \equiv \sigma \otimes I, \sigma_B \equiv I \otimes \sigma\), with \(\sigma' = (\sigma_x, \sigma_y, \sigma_z)\) the Pauli operators and \(I\) the identity (in the corresponding space).

The basic traces \(\text{tr} \sigma_\mu = 0\), \(\text{tr} \sigma_\mu \sigma_\nu = 2 \delta_{\mu \nu}\) for \(\mu, \nu = x, y, z\), ensure that

\[
\mu_A = \langle \sigma_A \rangle, \quad \mu_B = \langle \sigma_B \rangle, \quad J = \langle \sigma_A \sigma_B \rangle,
\]

i.e., \(J_{\mu \nu} = \langle \sigma_A \sigma_B \rangle\), where \(O = \text{Tr} \rho_{AB} O\).

Any complete local projective measurement in \(B\) can be considered as a spin measurement along the direction of a unit vector \(k\), represented by the orthogonal projectors \(P_{kk} = \frac{1}{2} (I \pm k \cdot \sigma)\). This leaves just those elements of \(\rho_{AB}\) proportional to \(k \cdot \sigma\), leading to the post-measurement state

\[
\rho_{AB}' = \frac{1}{2} \left[ I + (r_A \cdot \sigma_A + r_B \cdot k \cdot \sigma_B + (r_A' \cdot J) (k \cdot \sigma_B)) \right],
\]

which corresponds to \(r_B \rightarrow k k^r r_B\) and \(J \rightarrow J k k^r\) in Eq. (17). The information loss due to this measurement will be denoted as \(I_f = S_f (\rho_{AB}') - S_f (\rho_{AB})\).

We now show, using Eq. (13), that the general stationary condition for the measurement direction \(k\) is in \(B\) reads

\[
\alpha r_A + \alpha_j J r_A + \alpha J^r J k = 0, \tag{19}
\]

i.e., \(k \times (\alpha r_A + \alpha J r_A + \alpha J^r J k) = 0\), where \(\lambda\) is a proportionality factor and the coefficients \(\alpha\) are given by

\[
\alpha(1,2,3) = \frac{1}{4} \sum_{\mu, \nu = \pm 1} f'(p_{ij}^\mu) \left( \frac{\nu \mu}{|r_A + v J k|} \right) \left( \frac{\mu}{|r_A + v J k|} \right),
\]

with \(p_{ij}^\mu (\mu, \nu = \pm 1)\) the eigenvalues of Eq. (18):

\[
p_{ij}^\mu = \frac{1}{2} (1 + v r_B \cdot k + \mu |r_A + v J k|). \tag{21}
\]

**Proof.** The state (18) is diagonal in the conditional product basis formed by the eigenstates of \(k \cdot \sigma B\) and \((r_A + v J k) \cdot \sigma A\), with \(v = \pm 1\) the eigenvalues of \(k \cdot \sigma B\), which leads to the eigenvalues in Eq. (21). We can then write

\[
f' (\rho_{AB}') = \frac{1}{4} \sum_{\nu, \mu} f'(p_{ij}^\mu) \left( I + \mu \frac{r_A + v J k}{|r_A + v J k|} \cdot \sigma_B \right) (I + v k \cdot \sigma_B).
\]

Using now the basic trace relations and \([r \cdot \sigma, s \cdot \sigma] = 2i (r \times s) \cdot \sigma\), we obtain \(\text{Tr}_A [(r \cdot \sigma_A) (s \cdot \sigma_B)] = 4i (s \times J r) \cdot \sigma_B\) and hence

\[
\text{Tr}_A (f' (\rho_{AB}')) = i [k \times (\alpha \cdot r_A + \alpha_J J r_A + \alpha_j J^r J k)] \cdot \sigma_B.,
\]

with \(\alpha_i\) given by Eq. (20). Equation (13) leads then to Eq. (19). \(\square\)
We can check Eq. (19) directly. From Eq. (21), we have 
\[ \delta p^\mu = \frac{1}{2} \left( r_B + \mu \sum_{\alpha \in \{\pm\}} \delta \lambda_{\alpha} \right) \cdot \delta k \] for small changes \( \delta k \) in the measurement direction, with \( k \cdot \delta k = 0 \) since \( k \) is a unit vector. The condition \( \delta f^k = \sum_{\mu} \delta (p^\mu) \delta p^\mu = 0 \) then implies \( (\alpha_1 f^A + \alpha_2 f^J r_A + \alpha_3 f^J J k) \cdot \delta k = 0 \), which leads to Eq. (19) since \( \delta k \) is orthogonal to \( k \).

Writing \( k = (\sin \gamma \cos \phi, \sin \gamma \sin \phi, \cos \gamma) \), Eq. (19) leads to a transcendental system for \( \gamma, \phi \) [see Eq. (18)]. Equation (19) can also be seen as a self-consistent eigenvalue equation for the matrix \( (\alpha_1 f^A + \alpha_2 f^J r_A + \alpha_3 f^J J k) \), where the left-hand side of Eq. (19) [see also (34)].

Let us remark that the initial reduced local state \( \rho_B = tr_A \rho_{AB} = \frac{1}{2}(I + r_B \cdot \sigma) \) becomes
\[ \rho_B^0 = \frac{1}{2}(I + (r_B \cdot k)(k \cdot \sigma)) \] after the local measurement. The minimizing direction \( k \) will depend on the matrix \( J \) and may obviously deviate from \( r_B \), changing the local state. A “transition” in the direction of the least disturbing \( k \), from \( r_B \) to the direction of the main eigenvector of \( J^J J \), can then be expected from Eq. (19) as \( J \) increases from 0, whose details will in general depend on the choice of entropy (see Sec. III).

In the case of the original quantum discord [Eq. (11)], the extra local contribution in Eq. (16) leads to the modified stationary condition (see also [34])
\[ (\alpha_1 - \eta)f^A + \alpha_2 f^J r_A + \alpha_3 f^J J k = \lambda k, \]
where \( \eta = \frac{1}{2} \sum_{\mu=\pm} v f^\mu(p_\mu) = \frac{1}{2} \log(2/p_\mu) \), with \( p_\mu = \sum_{\nu} \rho^\nu_k \). The extra term \( -\eta r_B \) will tend to diminish the effect of \( r_B \), favoring the direction determined by \( f^J J \).

D. Quadratic and cubic information measures

While the evaluation of a general entropy \( S_f(\rho) \) requires the determination of the eigenvalues of \( \rho \), those choices of \( f \) involving just low integer powers of \( \rho \) allow one to determine \( S_f(\rho) \) without their explicit knowledge. For instance, using just the basic trace relations \( tr \sigma_\alpha = 0 \) and \( tr \sigma_\alpha \sigma_\beta = 2\delta_{\alpha\beta} \), the linear entropy (7) of any two-qubit state can be evaluated as
\[ S_f(\rho_{AB}) = \frac{1}{3} - \frac{1}{3} ||(r_A)^2 + |r_B|^2 + ||J||^2||, \] where \( ||J||^2 = tr f^J J \) and \( |r|^2 = r \cdot r = r^J J \). For the post-measurement state (18), Eq. (24) becomes
\[ S_f(\rho_{AB}) = \frac{1}{2} - \frac{1}{2} ||(r_A)^2 + |r_B|^2 + ||J||^2||, \]
where \( M_2 \) is a positive semidefinite symmetric matrix.

The information loss becomes therefore
\[ I_2^f = \frac{1}{2} ||(r_B)^2 + ||J||^2 - k \cdot M_2 k || = \frac{1}{2} (tr M_2 - k \cdot M_2 k). \] (27)

The minimum \( I_2^f \) is just twice the geometric discord, defined and evaluated for two qubits in [16]. It corresponds then to \( k \) directed along the eigenvector with the largest eigenvalue of the matrix \( M_2 \):
\[ I_2^f(\rho_{AB}) = \min_k I_2^f = \frac{1}{2} (tr M_2 - \lambda_1) = \frac{1}{2} (\lambda_2 + \lambda_3), \] where \( (\lambda_1, \lambda_2, \lambda_3) \) are the eigenvalues of \( M_2 \) sorted in decreasing order.

A state \( \rho_{AB} \) which is already of the form (18) leads to \( I_2^f(\rho_{AB}) = 0 \) for \( S_f \) and is then characterized by a matrix \( M_2 \) of rank 1 (such that \( \lambda_2 = \lambda_3 = 0 \)). It is verified that for \( f^J(p^\nu_k) \propto 1 - 2p^\nu_k \), Eq. (19) reduces to the present eigenvalue equation \( M_2 k = \lambda k \), since \( (\alpha_1 f^A + \alpha_2 f^J r_A + \alpha_3 f^J J k) \).

Another entropy and quantum correlation measure which can be evaluated in closed form for any state of two qubits is the geometric discord (18), such that \( S_f(\rho_{AB}) = \frac{1}{3} (2 - ||J^1||^2). \) Another entropy and quantum correlation measure which can be evaluated in closed form for any state of two qubits is the geometric discord (18), such that \( S_f(\rho_{AB}) = \frac{1}{3} (2 - ||J^1||^2). \)
Equations (24) and (30) provide in fact strict bounds on these invariants. As $S_2(\rho_{AB}) \geq 0 \forall \rho_{AB}$, Eq. (24) implies
\[ |\mathbf{r}_A|^2 + |\mathbf{r}_B|^2 + |J|^2 \leq 3, \] (35)
with $|\mathbf{r}_A|^2 + |\mathbf{r}_B|^2 + |J|^2 = 3$ if and only if $\rho_{AB}$ is pure [$\rho_{AB}^2 = \rho_{AB}$, $S_2(\rho_{AB}) = 0$]. Moreover, as $\text{Tr} \rho^2 \leq \text{Tr} \rho^3$ if $q^2 > q > 0$, for the present normalization we have $S_3(\rho) \geq \frac{1}{2} S_2(\rho)$, which for a two-state system implies $r'_{AB} J r_B - \text{det} J \leq 1 - \frac{1}{2} S_2(\rho_{AB})$. (36)
with $r'_{AB} J r_B - \text{det} J = 1$ if and only if $\rho_{AB}$ is pure. We can verify these results by writing a pure state of two qubits in the Schmidt basis, $|\Psi_{AB}\rangle = \sqrt{p} |00\rangle + \sqrt{1-p} |11\rangle$, with $p \in [0,1]$, which leads to $|\mathbf{r}_A|^2 = |\mathbf{r}_B|^2 = |2p - 1|$, $|J|^2 = 1 + 8p(1-p)$, $r'_{AB} J r_B = (2p - 1)^2$ and det $J = -4p(1-p)$, and hence to equality in Eqs. (35) and (36).

An important final remark concerning the quadratic and cubic entropies is that for an arbitrary single-qubit state $\rho_A = \frac{1}{2} (I_z + \mathbf{r} \cdot \sigma)$ they are identical, since $\text{tr}_{\rho_m}^m = 0$ for $m$ odd:
\[ S_2(\rho_A) = S_3(\rho_A) = 1 - |\mathbf{r}_A|^2. \] (37)
This entails that the corresponding entanglement monotonies [45] for a two-state system are also identical [17], coinciding with the square of the concurrence $C_{AB} [36,37]$. Both quantities $J^2_2$ and $I^2_B$ reduce then to the squared concurrence $C^2_{AB}$ in the case of a pure two-qubit state.

This last result can be directly verified using the previous Schmidt decomposition. Both matrices $M_2$ and $M_3$ become diagonal in the ensuing $z$ basis, their two lowest eigenvalues being identical: $\lambda_2 = \lambda_3 = 4p(1-p) = -\text{det} J$. Equations (28) and (31) then lead to $I^2_B = I^2_2 = 4p(1-p)$, which is just the square of $C_{AB} = 2\sqrt{p(1-p)}$.

**III. APPLICATION**

A. States with maximally mixed reduced states

As a first example, let us consider $\rho_A = \rho_B = 0$ in Eq. (17), such that $\rho_A = \rho_B = \frac{1}{2} I$ and $\rho_{AB} = \frac{1}{2} (I + \sigma_A^f J \sigma_B)$. (38)

We will show the following for the state given in Eq. (38):

(a) The measurement direction $\mathbf{k}$ in system $B$ minimizing $I^B_J$ is universal, the same for any entropy $S_f$, and given by that of the eigenvector with the largest eigenvalue of the matrix $J J'$.

(b) The ensuing minimum information loss is given by $I^B_J(\rho_{AB}) = 2 f \left( \frac{p_1 + p_2}{2} \right) + 2 f \left( \frac{p_1 + p_3}{2} \right) - f(p_1) - f(p_3) - f(p_1) - f(p_3).$ (39)

where $(p_1, p_2, p_3, p_4)$ are the eigenvalues of Eq. (38) sorted in decreasing order.

(c) $I^J_f = I^B_J / f$, the minimizing direction in $A$ being that of the eigenvector with the largest eigenvalue of $J J'$.

**Proof of (a).** For $r_A = r_B = 0$, the eigenvalues in Eq. (21) of $\rho_{AB}'$ become $p_i^B(\mathbf{k}) = \frac{1}{2} (1 + \nu \mu |Jk|)$, being two-fold degenerate. If $\mathbf{k}_m$ is the normalized eigenvector with the largest eigenvalue ($J^m_2$) of $J J'$, we have $|Jk| = \sqrt{k' J' J k} \leq \sqrt{k_m J' J k_m} = |J_m|^2$ for any unit vector $\mathbf{k}$, and hence $p^B_m(\mathbf{k}) \leq p^B_m(\mathbf{k}_m)$. This implies that the distribution $\{p^B_m(\mathbf{k})\}$ is majorized [41] by $\{p^B_m(\mathbf{k}_m)\}$, i.e.,
\[ r'_{AB}(\mathbf{k}) < r'_{AB}(\mathbf{k}_m) = \frac{1}{2} \left[ I + J_m (\tilde{k}_m \cdot \sigma_A)(\mathbf{k}_m \cdot \sigma_B) \right]. \] (40)
where $\tilde{k}_m = J m / J m$ is the corresponding eigenvector of $J J'$, entailing $S_f(\rho'_{AB}(\mathbf{k})) \geq S_f(\rho'_{AB}(\mathbf{k}_m))$ and hence $I^J_f \geq I^J_f \forall \mathbf{k}$ and $S_f$. The state $\rho'_{AB}(\mathbf{k}_m)$ is thus the least mixed classical state associated with $\rho_{AB}$, and measurement along $\mathbf{k}_m$ the least disturbing local measurement (in $B$) for any $S_f$. According to the general stationary condition (19), leads in this case to the eigenvalue equation $J' J \mathbf{k} = \lambda \mathbf{k} \forall \mathbf{k}$, with $M_2 = M_3 = J' J$ in Eqs. (26) and (32).

This result is apparent. The local axes can be always chosen such that the matrix $J$ is diagonal. This can be achieved through its singular value decomposition $J = U_A J^d U_B^t$, where $J^d = J_\mu \delta_{\mu \mu}$, with $J^d_\mu$ the eigenvalues of $J' J$ (the same as those of $J' f'$) and $U_A, U_B$ orthonormal matrices ($U_A U_B^t = I$). The signs of the $J_\mu$ should be chosen such that $U_A$ are rotation matrices (det $U_A = +1$). Replacing $\sigma_a \rightarrow U_a \sigma_a$ in Eq. (38), we then obtain
\[ \rho_{AB} = \frac{1}{4} \left( I + \sum_{\mu=x,y,z} J_\mu \sigma_{A\mu} \sigma_{B\mu} \right). \] (41)

Since $|J_m| = \max(|J_1|, |J_2|, |J_3|)$, the universal least disturbing measurement is, therefore, along the maximally correlated direction, leaving the largest term of Eq. (41) in the post-measurement state of Eq. (40). Note that Eq. (41) satisfies Eqs. (15) in a product basis formed by the eigenstates of $\sigma_{A\mu} \sigma_{B\mu}$, for any $\mu = x, y, z$.

**Proof of (b).** Equation (41) is diagonal in the Bell basis $\{|\Psi_{1,2}\rangle = \frac{|00\rangle \pm |11\rangle}{\sqrt{2}}, |\Psi_{3,4}\rangle = \frac{|01\rangle \pm |10\rangle}{\sqrt{2}}$, i.e., $\rho_{AB} = \sum_i p_i |\Psi_i\rangle \langle \Psi_i|$, with eigenvalues
\[ p_{1,2} = \frac{1 + J_z \pm (J_x - J_y)}{4}, \quad p_{3,4} = \frac{1 - J_z \pm (J_x + J_y)}{4}. \]
Without loss of generality we may always choose the local axes $x, y, z$ such that $|J_m| = |J_x| \geq |J_y| \geq |J_z|$, with $J_z \geq 0$ and $J_x \geq 0$ (rotations of angle $\pi$ around one of the axes in $A$ or $B$ lead to $J_\mu \rightarrow -J_\mu$ for the other axes). In such a case $p_1 \geq p_2 \geq p_3 \geq p_4$, and the least disturbing measurement is along $z$, such that Eq. (40) becomes
\[ r'_{AB}(\mathbf{k}_m) = \frac{1}{4} (I + J_z \sigma_A \sigma_{Bz}), \] (42)

having degenerate eigenvalues
\[ \frac{1 + J_z}{4} = \frac{p_1 + p_2}{2}, \quad \frac{1 - J_z}{4} = \frac{p_3 + p_4}{2}. \]

The minimum information loss $I^B_J = S_f(\rho'_{AB}(\mathbf{k}_m)) - S_f(\rho_{AB})$ becomes therefore Eq. (39), where $(p_1, p_2, p_3, p_4)$ are in general the eigenvalues of $\rho_{AB}$ sorted in decreasing order.

**Proof of (c).** Since Eq. (39) is fully determined by the sorted eigenvalues of $\rho_{AB}$, we have obviously $I^J_f = I^B_J$, a result which is apparent from the symmetric representation (41). From Eq. (40) it is seen that the minimizing measurement in $A$ is along $\mathbf{k}_m$. ■
Let us now discuss the main features of Eq. (39). It is verified that the strict concavity of $f$ ensures $I_f^B(\rho_{AB}) \geq 0 \forall S_f$, with $I_f^B(\rho_{AB}) = 0$ only if $p_1 = p_2$ and $p_3 = p_4$, in which case $\rho_{AB} = \rho_{AB} = p_1(10)(10) + (11)(11) + p_3(01)(01) + (10)(10)$ is a classically correlated state.

In the von Neumann case $f(p) = -p \log_2 p$, Eq. (39) is just the quantum discord $D^A = D^B$ of the state, coinciding with the result of Ref. [29]. For the states (38), $\hat{\rho}_B = \rho_B = \frac{1}{2}I$ for any $M_B$, entailing that the quantum discord of Eq. (11) reduces to the information deficit, i.e., to the present quantity $I_f^B$ for the von Neumann choice of $f$.

In the quadratic case of Eq. (7), Eqs. (28) or (39) lead to

$$I_f^B(\rho_{AB}) = \frac{1}{2}(J_2^A + J_2^B) = (p_1 - p_2)^2 + (p_3 - p_4)^2,$$

(43)

which is just twice the geometric discord of the state, whereas in the cubic case [Eq. (30)], Eqs. (31) or (39) lead to

$$I_f^B(\rho_{AB}) = \frac{1}{2}(J_2^A + J_2^B) - \frac{1}{2}J_1J_3,$$

(44a)

$$= (p_1 - p_2)^2(p_1 + p_2) + (p_3 - p_4)^2(p_3 + p_4),$$

(44b)

which is just the average of the terms in Eq. (43) and implies $I_f^B(\rho_{AB}) \leq I_f^B(\rho_{AB})$.

Let us notice that for small $J_{\mu}$, Eq. (39) becomes in fact proportional to Eq. (43) for any $S_f$; setting $J_{\mu} = J_z$,

$$I_f^B(\rho_{AB}) \approx \frac{1}{2}c_f(J_2^A + J_2^B) + O(J_3) = c_f^2 I_f^B(\rho_{AB}) + O(J_3),$$

(45)

with $c_f = -\frac{1}{2}f''(\frac{1}{2}) > 0$. This implies a universal quadratic behavior in the vicinity of the maximally mixed state I/4, in agreement with the general results of [17].

Relation with entanglement. It is well known that the state (38) is entangled if and only if its largest eigenvalue $p_1$ satisfies $p_1 > 1/2$. Its concurrence [36] is given by

$$C_{AB} = \text{Max}[2p_1 - 1, 0],$$

(46)

with $2p_1 - 1 = p_1 - p_2 - p_3 + p_4$. This implies

$$I_f^B \geq C_{AB}^2, I_f^B \geq C_{AB}^2,$$

(47)

with equality for $C_{AB} > 0$ valid in both cases only if $p_1 = p_2 = 0 [C_{AB} \leq (p_1 - p_2)^2 - (p_1 - p_2)(p_3 + p_4) \leq (p_3 - p_4)^2(p_1 + p_2) if p_3 + p_4 \leq p_1 - p_2]$. Equation (47) means that for the states (38), $I_f^B$ and $I_f^B$ are both upper bounds to their corresponding entanglement monotones. This is not a general property. For instance, it is not valid in the von Neumann case $f(p) = -p \log_2 p$, where Eq. (39) can be lower than the entanglement of formation $E_{AB} = \sum_{\nu=1}^4 f(1 + \sqrt{1 - C_{AB}^2})$ [36] for the present states.

Figure 1 depicts the maximum and minimum values reached by $I_f^B$ and $I_f^B$ in the states (38) for fixed values of the maximum eigenvalue $p_1$. The common minimum is just the squared concurrence $C_{AB}^2$ reached for $p_1 = p_2 = 0$ if $p_1 \geq 1/2$ (and $p_3 = p_1$, $p_3 = p_4$ if $p_1 \leq 1/2$). The maximum is reached for $p_2 = p_3 = p_4$ if $p_1 \geq 7/13 \approx 0.54$ for $I_f^B$ and $p_1 \geq 0.44$ for $I_f^B$, and for $p_2 = p_3$, $p_3 = 0$, if $p_1$ lies below the previous values and above 1/3. As a result, the maximum values for zero concurrence of $I_f^B$ and $I_f^B$ within these states are 1/8 and 2/27, respectively, obtained at $p_1 = 1/2$.

In contrast, in the von Neumann case the minimum (again obtained for $p_1 = p_2 = 0$ if $p_1 \geq 1/2$) lies clearly below $E_{AB}$ for $p \in (1/2, 1)$, and even the maximum (attained at $p_2 = p_3 = p_4$ if $p \geq 0.86$ and $p_2 = p_3$, $p_4 = 0$ if $1/3 \leq p_1 \leq 0.86$) lies below $E_{AB}$ if $p_1 \geq 0.91$. If $p \leq 1/3$ the maximum in these three measures is reached for $p_2 = p_3 = p_1$.

B. States with parity symmetry

Let us now consider the case where both $r_A$ and $r_B$ are directed along the same principal axis, i.e., $r_A$ along $k$ and $r_B$ along $J_k$, with $k$ an eigenvector of $J'J$ (and hence, $J_k$ an eigenvector of $J'J$). Choosing these axes as the local $z$ axes, such that $r_A = r_A k_z$, $r_B = r_B k_z$, and $J_{\mu z} = J_{\mu z} \delta_{\mu z}$, such state can be written as

$$\rho_{AB} = \frac{1}{4} \left[ I + r_A \sigma_{A z} + r_B \sigma_{B z} + \sum_{\mu = x, y, z} J_\mu \sigma_{A \mu} \sigma_{B \mu} \right]$$

$$= \frac{1}{4} \left( \begin{array}{ccc} a_+ & 0 & 0 \\ 0 & c_+ & \alpha_+ \\ 0 & \alpha_- & c_- \end{array} \right),$$

(48)

where the matrix is the representation in the standard basis of $\sigma_{A z} \sigma_{B z}$, eigenstates. This state commutes with the spin-parity [38] $P_z = -\exp(\pi(\sigma_{A z} + \sigma_{B z})/2)$. It is also denoted as an $X$ state [32].

We will now show that a measurement of $\sigma_B$ along any of the principal axes $x, y, z$ will provide a stationary point of $I_f^B \forall S_f$.

Proof: For a measurement along the $z$ axis ($k = k_z$), $r_A$, $r_B$, and $J'J_k = J_z^2 k_z$ are all along this axis and Eq. (19) is trivially satisfied $\forall \alpha$. It is a particular case of Eq. (15), which here holds in the standard basis.
For a measurement along the $x$ axis ($k = k_x$), $J'k_x = J_x k_x$, while $r_B \cdot k_x = 0$ and $|a_A + v J k_x| = \sqrt{\gamma^2 + \gamma'}^2$. Hence $p_{\mu}^\nu = \frac{1}{4}(1 + \mu |r_A + v J k_x|)$ is independent of $v$. This leads to $a_1 = a_2 = 0$ in Eq. (20), in which case Eq. (19) is again satisfied. For $k = k_x$, the argument is similar. We also remark that these arguments also apply to the quantum discord [Eq. (11)], as $\eta = 0$ in Eq. (23) for $k = k_x$ or $k_y$.

While other stationary directions may also exist, the principal axes are strong candidates for minimizing $I_B^\parallel$. Typically, the minimum will be attained for measurements along $z$ if $\max(|J_x|, |J_z|)$ is sufficiently small, while otherwise measurements along $x$ or $y$ can be preferred. A transition between these two regimes will arise as $J_x$ or $J_z$ increases, whose details will depend on the entropic function and may involve intermediate directions $k$.

Writing $k = (\sin \gamma \cos \phi, \sin \gamma \sin \phi, \cos \gamma)$, these intermediate solutions can be found from Eq. (19), which leads here to $\phi = 0$ or $\phi = \pi/2$ if $|J_x| > |J_z|$, the minimum corresponds to $\phi = 0$ for any $S_r$, as the ensuing distributional majorizes that for $\phi = \pi/2$ and to $\gamma = 0$ or

$$\cos \gamma = \frac{\alpha_1 r_B + \alpha_2 J_z r_A}{\alpha_3 (J_z^2 - J_x^2)} ,$$

where we have assumed $|J_x| > |J_z|$ such that $\phi = 0$. The intermediate solutions $|\gamma| \in (0, \pi/2)$ of Eq. (49), if existent, are degenerate, as both choices $\pm \gamma$ lead to the same $I_B^{\parallel}$. Just the principal axes solutions are nondegenerate.

The final expression for $I_B^\parallel$ is formally

$$I_B^\parallel = \frac{1}{4}(1 + \nu r_B k_z + \mu |r_A + v J k_x|)$$

where $p_{\mu}^\nu = \frac{1}{4}(1 + \nu r_B k_z + \mu |r_A + v J k_x|)$ are the eigenvalues [Eq. (21)] of $\rho_A^B$, and $\lambda_{\mu}^\nu$ those of $\rho_{AB}^B$:

$$\lambda_{\mu}^\nu = \frac{1}{4}(1 + \nu J_z + \mu |r_A + v J k_x|)^2 + (J_z - v J_x)^2$$.  

We can verify the previous results in the quadratic and cubic cases. For an $X$ state, both matrices $M_2$ and $M_3$ [Eqs. (26) and (32)] are diagonal in the principal axes basis:

$$M_{2_{\alpha\beta}} = \delta_{\mu\nu} (J_{\mu}^2 + \delta_{\mu\nu} r_B^2)$$

$$M_{3_{\alpha\beta}} = \delta_{\mu\nu} (J_{\mu}^2 + \delta_{\mu\nu} (r_A^2 + 2 r_B r_A J_x))$$

Hence, the optimum measurement will be along the axis with the maximum diagonal value and no intermediate solutions will arise (for nondegenerate eigenvalues), as opposed to the general case. Assuming $|J_x| < |J_z|$, a “sharp” $z \rightarrow x$ transition for the least disturbing measurement will then take place, the $x$ axis preferred for

$$J_x > J_z + r_B^2, \quad q = 2,$$

$$J_x > J_z + r_B^2 + 2 r_B r_A J_x, \quad q = 3,$$

in the quadratic and cubic cases, respectively, such that

$$I_B^\parallel (\rho_{AB}) = \frac{1}{2} [J_z^2 + \min(J_x^2, r_B^2 + J_z^2)] ,$$

$$I_B^\parallel (\rho_{AB}) = \frac{1}{2} [J_z^2 - 2 J_x J_z + \min(J_x^2, r_B^2 + J_z^2 + 2 r_B r_A J_x)] .$$

These expressions are in general no longer upper bounds to the squared concurrence, which for these states is $C_{AB}^2 = \frac{1}{2} \max(\alpha_{++} - \sqrt{\alpha_{++}^2 - \alpha_{-1}^2 - \alpha_{-1}^2}, \alpha_{-1} - \sqrt{\alpha_{-1}^2 - \alpha_{-1}^2 - \alpha_{-1}^2})$. Nonetheless, $I_B^\parallel$ remains an upper bound to $C_{AB}^2$ in the “$c$ phase”, as $C_{AB}^2 \leq \frac{1}{2}(\langle J_x \rangle + |J_z|)^2 \leq \frac{1}{2}(J_x^2 + J_z^2)$.

C. Mixture of aligned states

As a particular relevant example of Eq. (48), we will consider the mixture of two states with spins aligned along different directions. Choosing the $z$ axis as the bisector, such state can be written as

$$\rho_{AB} = \frac{1}{2} (|\theta\theta\rangle \langle \theta\theta| + |\theta - \theta\rangle \langle \theta - \theta|) ,$$

which corresponds to $(J_x, J_z) = (\sin^2 \theta, 0, \cos^2 \theta)$ and $r_A = r_B = \cos \theta$ in Eq. (48). Here

$$\theta = \exp \left[ -i \frac{\theta}{2} J_x \right] \langle 0 | \cos \theta \frac{\theta}{2} + \sin \theta \frac{\theta}{2} \rangle$$

is the state with the spin forming an angle $\theta$ with the $z$ axis in the $(x,z)$ plane. The relevance of this state was discussed in [33]. It represents, roughly, the state of a spin pair in the definite parity ground state of a finite $n$ spin ferromagnetic type $XY$ spin chain in a transverse field for $|B| < B_c$, and the exact state of any pair at the immediate vicinity of the factorizing field [38] (neglecting small coherence terms $\propto \cos^{\alpha - 2} \theta$).

This state is separable, i.e., it is a convex mixture of product states [8], and the concurrence $C_{AB}$ accordingly vanishes $\forall \theta$. Nonetheless, it has nonzero discord [33] if $\theta \in (0, \pi/2)$. It will then have nonzero values of any $I_B^\parallel$ in this interval, with $I_B^\parallel = I_B^\parallel \forall S_f$ due to the symmetry of the state. For $\theta = 0$ it is obviously a pure product state, while for $\theta = \pi/2$ it is a classically correlated state, i.e., diagonal in a standard product basis, implying $I_B^\parallel (\rho_{AB}(\theta)) = 0$ for $\theta = 0$ or $\pi/2 \forall S_f$.

It can be expected that as $\theta$ increases, the least disturbing measurement will change from $z$ to $x$. In the quadratic and cubic cases, the transition is sharp. We obtain, according to Eqs. (52)–(55),

$$I_B^\parallel = \frac{1}{2} \left\{ \sin^4 \theta \cos^2 \theta + \cos^4 \theta \sin^2 \theta \right\} , \quad \theta < \theta_c ,$$

$$I_B^\parallel = \frac{1}{4} \left\{ \sin^4 \theta \cos^2 \theta + 3 \cos^4 \theta \sin^2 \theta \right\} , \quad \theta > \theta_c ,$$

where $\cos^2 \theta_c = 1/3 (\theta_c \approx 0.61 \pi/2)$ and $\cos^2 \theta_c = (\sqrt{7} - 3)/4 (\theta_c \approx 0.64 \pi/2)$, with the minimizing measurement changing from $z$ to $x$ for $\theta > \theta_c$. These two quantities exhibit then a cusplike maximum at $\theta = \theta_c$, i.e., slightly above $\pi/4$, as seen in Fig. 2.

On the other hand, for other entropies a smooth transition from $z$ to the $x$ direction can arise. For instance, in the von Neumann case, $z$ is preferred exactly for $\theta = \pi/4$, but $x$ is minimum only for $\theta > 0.64 \pi/2$. In between, the optimum measurement is obtained for an intermediate angle $\gamma$, as
3) cases, whereas in the von Neumann case (depicted above. It is seen that smooth. No transition arises in the case of the quantum discord.

The least disturbing measurement angle \( \gamma \) vs \( \theta \) for the same cases depicted above. It is seen that \( \gamma \) exhibits a sharp transition from 0 to \( \pi/2 \) (i.e., from \( z \) to the \( x \) axis) in the quadratic \((q = 2)\) and cubic \((q = 3)\) cases, whereas in the von Neumann case \((q = 1)\) the transition is smooth. No transition arises in the case of the quantum discord.

IV. CONCLUSIONS

We have analyzed the determination of the minimum information loss \( I^B_\theta \) associated with an unread local measurement in a bipartite system, for a general entropy \( S_f \). Such a quantity is a measure of the quantum correlations lost in the local measurement, and reduces to the information deficit and the geometric discord when \( S_f \) is chosen as the von Neumann and linear discord, respectively. A general stationary condition was derived, together with its explicit form for an arbitrary mixed state of two qubits. Explicit expressions for the cubic entropy and the associated measure \( I^B_\theta \) were in this case obtained, which require, as in the quadratic case (geometric discord), just the eigenvalues of a \( 3 \times 3 \) matrix.

As an application, we first examined two-qubit mixed states with maximally mixed marginals, where the minimum information loss \( I^B_\theta \) for any entropy was shown to be a simple function of the eigenvalues of \( \rho_{AB} \). The minimizing measurement is in this case universal. Moreover, in this case \( I^B_\theta \) and \( I^B_2 \) were shown to be strict upper bounds of the squared concurrence, which is the associated entanglement monotone for both entropies. We have also analyzed the case of \( X \) states, providing explicit expressions for \( I^B_3 \) and \( I^B_2 \) and showing that spin measurements along the principal axes of the matrix \( J'J \) are universal stationary points of \( I^B_\theta \) for any \( S_f \).

Finally, the special case of a mixture of aligned states was examined in detail. Here the least disturbing local measurement changes, for all measures \( S_f \), from the \( z \) (bisector axis) to the \( x \) axis as the angle \( 2\theta \) between both directions changes from 0 to \( \pi \), being then different from that optimizing the original quantum discord (which stays constant), although the type of transition depends on the information measure employed. The least disturbing measurement according to \( I^B_\theta \) is thus more sensible to the strength of the correlation, and reflects the "transition" experienced by the state. Application of the present formalism to more complex systems is currently under investigation.
