(Dated: Tuesday 15th September, 2015)

In this paper we study the Dirac field theory interacting with external gravitation field, described with tetrad of the form \( e^a_\mu(x) = \varepsilon (\delta^a_\mu + \omega^a_{\mu
u} x^\nu) \), where \( \varepsilon = 1 \) for \( \mu = 0 \) and \( \varepsilon = i \) for \( \mu = 1, 2, 3 \). The probability density of the vacuum-vacuum pair creation is given. In particular case of vanishing electromagnetic fields, we point out how this deformation modify the amplitude transition. The corresponding Dirac equation is solved.

I. INTRODUCTION

The Dirac particle theory arise in the theoretical description of the fermion particles phenomena. They also become central to elementary particle physics, as the starting point for quantum theory of electromagnetic interaction. In the past few years this theory have been widely studied in various curved backgrounds due to its importance in both astrophysics and cosmology, as well as in the study of particle creation processes [1]-[6]. Pair production is a phenomenon of nature where energy is converted to mass. nevertheless there are only few problems for which the Dirac equation can be solved exactly. Some of them are give in [7]-[15] and references therein. The explicit solution is crucial in the particle creation processes and is the base of the standard cosmological model [25]-[27]. This amounts to claim that, the formulation and behaviour of fermion particles physics including the gravitation field is performed using solution of Dirac equation.

In the present work, the transition amplitude and the probability density of the pair creation of the Dirac particle is examined in the twisted Minkowsky space-time. A solution of the Dirac equation is proposed. The metric is chosen to be the first-order deformation of flat Minkowsky pseudo-metric tensor \( g^{\mu\nu} \). We pointed out how this deformation of flat metric modify the well know probability density of creation of Dirac particle, a while ago computed in [2], [4] and references therein.

The paper is organized as follows. In section (II), we quickly review Dirac particle theory, interacting with gravity field. In (III) we compute the probability density of pair production. The case of vanishing electromagnetic fields is examined. The solution of the corresponding Dirac equation is proposed in the section (IV). In the last section (V), we conclude our work and make some remarks.

II. DIRAC EQUATION COUPLED WITH A WEAK GRAVITATION FIELD

In the curve space-time the conventional affine connection \( \nabla_\mu \) is replaced by the spin connection \( \Gamma_\mu \) which is expressed in terms of the vierbein fields \( e^a_\mu(x) \) (see [16]-[24]). Then any curved space description of physics can be replaced by an equivalent and simpler flat space physics, through the vierbein transformation. There was an equivalent formulation of general relativity involving the dynamics of the so-called spin-connection. This approach came to be known as Einstein-Cartan theory and leads to consider general relativity as gauge theory approach of gravity [18].

An arbitrary geometrical object defined on the Riemann space-time manifold can be locally projected on the tangent Minkowski space, simply by contracting its curved indices with the vierbein and its inverse. For rank \( n \) tensor object \( T \), we can write

\[
T^{a_1 a_2 \cdots a_n} = e^{a_1}_{\mu_1}(x)e^{a_2}_{\mu_2}(x) \cdots e^{a_n}_{\mu_n}(x) \tilde{T}^{\mu_1 \mu_2 \cdots \mu_n},
\]

\[
T_{a_1 a_2 \cdots a_n} = e^{\mu_1}_{a_1}(x)e^{\mu_2}_{a_2}(x) \cdots e^{\mu_n}_{a_n}(x) \tilde{T}_{\mu_1 \mu_2 \cdots \mu_n},
\]

where the Latin indices \((a, b, c, \cdots)\) is used only for the flat space-time and the Greek indices \((\alpha, \beta, \mu, \cdots)\) for the curve space-time. The “tilde notation” is used only for the curve space variables. \( e^a_\mu(x) \) represent the inverse of \( e^a_\mu(x) \). The metric tensors \( g^{\mu\nu} \) and \( \eta^{ab} = \text{diag}(1, -1, -1, -1) \) are related by \( g^{\mu\nu}(x) = e^{\mu}_a(x)e^\nu_a(x)\eta^{ab} \), or \( \eta^{ab} = e^a_\mu(x)e^b_\nu(x)g^{\mu\nu}(x) \).

The connection \( \Gamma_\mu \) is

\[
\Gamma_\mu =: \frac{1}{4} g_{\alpha\beta} \left( \frac{\partial e^a_\alpha}{\partial x^\mu} e^\beta_a - \Gamma^{b}_{\mu\nu} \right) \tilde{e}^{a\alpha\beta},
\]

where \( \tilde{e}^{a\alpha\beta} = \frac{1}{2} [\gamma^\alpha(x), \gamma^\beta(x)] \).

We consider the Dirac equation coupled with both gravitational and EM fields, given by the following relation

\[
(i\overline{\gamma}^\mu(x)D_\mu - m)\psi(x) = 0, \tag{4}
\]

where \(D_\mu = \partial_\mu - \Gamma_\mu + iA_\mu\). In this expression, the vectors \(\Gamma_\mu\) and \(A_\mu\) are respectively the gravitational and EM gauge vectors. The field \(\psi\), is a four-components complex function of space-time coordinates \(x^\mu, \mu = 0, 1, 2, 3\). The Dirac gamma matrices \(\overline{\gamma}^\mu(x)\), acting on the vector fields \(\psi\), satisfy the anti commutation formula:

\[
\{\overline{\gamma}^\mu(x), \overline{\gamma}^\nu(x)\} = 2g^{\mu\nu} \text{ such that } \overline{\gamma}^\mu(x) = e^\mu_i(x)\gamma^i. \tag{5}
\]

The flat space-time gamma matrices \(\gamma\) are expressed with the Pauli matrices \(\sigma^i\), \(i = 1, 2, 3\) by

\[
\gamma^0 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad \gamma^i = \begin{pmatrix} 0 & \sigma^i \\ -\sigma^i & 0 \end{pmatrix}, \quad i = 1, 2, 3. \tag{6}
\]

Remark that the equation (4) provided from the Euler-Lagrange equation of motion of the action \(S\):

\[
S = \int d^4x \sqrt{-g} \left(i\overline{\psi}\overline{\gamma}^\mu(x)D_\mu\psi - m\overline{\psi}\psi\right), \tag{7}
\]

where \(\overline{\psi} = \psi^\dagger\overline{\gamma}^0(x)\).

The dynamics described by the relation (4) is invariant under an external local transformation of Lorentz group. In the case of internal local transformation this invariance is satisfy for the dynamics occurring within the space-time manifold. The symmetries of this internal space are chosen to be the gauge symmetries of some gauge theory, so a unified theory would contain gravity together with the other observed fields.

For \(|\omega_0^a| < < 1\), we consider the vierbein field \(e^\mu_a(x)\) as

\[
e^\mu_a(x) = \text{diag} \left[1 + \omega_0^0 x^a, i(1 + \omega_1^1 x^a), i(1 + \omega_2^2 x^a), i(1 + \omega_3^3 x^a)\right]. \tag{8}
\]

We shall use the notation \(\omega_a^a x^a = :\omega_a^a x^a\). Then, the metric tensor \(\tilde{g}^{\mu\nu} = :\eta^{\mu\nu} + f^{\mu\nu}\) (where \(f^{\mu\nu}\) is the perturbation tensor), takes the form

\[
(\tilde{g}^{\mu\nu}) = \text{diag} \begin{bmatrix} 1 + 2\omega_0^0 x^a & -1 - 2\omega_1^1 x^a \\ -1 - 2\omega_2^2 x^a & 1 + 2\omega_3^3 x^a \end{bmatrix}, \tag{9}
\]

such that the limit where \((\omega) \rightarrow 0\) restore the Minkowsky pseudo-metric. \(\tilde{g}^{\mu\nu}\) can be considered as the first-order fluctuation of the flat Minkowsky pseudo-metric. Now let us choose the tensor \((\omega)\) such that the metric depend only on the coordinates \((t = x^0, x = x^1)\), i.e.

\[
\omega_0^0 = \omega_0^1 = 0, \quad \omega_0^a = \omega, \quad \omega_1^a = \overline{\omega}. \tag{10}
\]

The vector \(\Gamma_\mu\) is

\[
(\Gamma_\mu) = \begin{pmatrix} \Gamma_0 \\ \Gamma_1 \\ \Gamma_2 \\ \Gamma_3 \end{pmatrix} = \begin{pmatrix} \frac{\omega_0^0}{2} \gamma_0^1 - \frac{\omega_0^1}{2} \gamma_1^0 \\ \frac{\omega_0^0}{2} \gamma_1^1 - \frac{\omega_0^1}{2} \gamma_0^2 \\ \frac{\omega_0^0}{2} \gamma_2^0 - \frac{\omega_0^1}{2} \gamma_1^1 - \frac{\omega_0^3}{2} \gamma_2^2 \\ \frac{\omega_0^0}{2} \gamma_3^0 - \frac{\omega_0^1}{2} \gamma_1^1 - \frac{\omega_0^2}{2} \gamma_2^2 - \frac{\omega_0^3}{2} \gamma_3^3 \end{pmatrix}. \tag{11}
\]

We get the following result:

**Proposition 1.** The Dirac equation in the curve background defined with the metric (9) and coupled with EM fields \(A_\mu = (0, 0, Bx, -Et)\) is given by

\[
\left[i\gamma^0 \partial_0 - \gamma^i \partial_i - i\gamma^0 Bx + i\gamma^3 Et + 9i\omega^0 \gamma_3 - 3\overline{\omega} \gamma^3 \right] \psi(x^\mu) = 0, \quad j = 1, 2, 3. \tag{12}
\]

The solution of the corresponding equation can be split into

\[
\psi(t, x, y, z) = \psi(t, x) \exp \left[i(k_2 y + k_3 z)\right], \tag{13}
\]

where \(\psi(t, x)\) is a function which depends only on \(t\) and \(x\).

**Proof.** Using the relation (8), the Christoffel tensors are:

\[
\Gamma^a_{\bar{a}b} = -\omega^a_0, \quad \Gamma^b_{\bar{a}b} = -\omega^b_0, \\
\Gamma^a_{aa} = \eta_{aa} \omega^a_0, \quad \Gamma^a_{ab} = 0, \quad a \neq b \neq c. \tag{14}
\]

where the Einstein summation are not taking into account in the above relations. Also the components of the Lorentz connection are

\[
\Gamma_0 = \frac{i}{2} \left(\omega^0_0 \sigma^{01} + \omega^0_2 \sigma^{02} + \omega^0_3 \sigma^{03}\right), \tag{15}
\]

\[
\Gamma_1 = -\frac{1}{2} \left(\omega^1_0 \sigma^{10} - \omega^2_1 \sigma^{12} - \omega^3_1 \sigma^{13}\right), \tag{16}
\]

\[
\Gamma_2 = -\frac{1}{2} \left(\omega^2_0 \sigma^{20} - \omega^3_2 \sigma^{21} - \omega^0_2 \sigma^{23}\right), \tag{17}
\]

\[
\Gamma_3 = -\frac{1}{2} \left(\omega^3_0 \sigma^{30} - \omega^0_3 \sigma^{31} - \omega^2_3 \sigma^{32}\right), \tag{18}
\]

which are reduced to (11) using (10), and \(\sigma^{ab} = \frac{1}{2}[\gamma^a, \gamma^b]\). Now, by replacing the expressions (15) in (4), the Dirac equation becomes

\[
\left(i\overline{\gamma}^\mu(x)\partial_\mu - \overline{\gamma}^\mu(x)A_\mu + \omega_a \gamma^a - m\right)\psi(x^\mu) = 0, \tag{19}
\]

where \(\omega_0 = \omega_0^0 + \omega_0^2 + \omega_0^3\) = \(3i\overline{\omega}\), \(\omega_1 = (\omega_1^0 - \omega_1^2 - \omega_1^3) = -\overline{\omega}\), \(\omega_2 = (\omega_2^0 - \omega_2^1 - \omega_2^3) = 0\), \(\omega_3 = (\omega_3^0 - \omega_3^1 - \omega_3^2) = 0\). We choose the external electromagnetic field as \(E = E_0 x^1, B = B_0 x^2\), where \(e_0\) is the unit vector in \(x^1\) direction. One solution of the Maxwell equation is then \(A_0 = (0, 0, Bx, -Et)\). Finally, the relation (12) is well satisfy.
III. TRANSITION AMPLITUDE OF THE MODEL

In this section we study, how this new metric modify the pair creation of fermion particles. We consider the Hilbert space of coordinate vectors $H_x$ such that the space-time coordinates $x^\mu = (x^0, x^1, x^2, x^3) = (t, x, y, z)$ are eigenvalue of coordinate operators $X^\mu = (t, X, Y, Z)$ acting on $H_x$, i.e. for $|t, x, y, z > \in H_x$

$$X^\mu|t, x, y, z> = x^\mu|t, x, y, z>.$$ (20)

The Hilbert space of momentum space vectors $H_p$ is defined as the Fourier transformation of $H_x$. The momentum operator $P_\mu = (P_0, P_1, P_2, P_3)$, $P_0 = i\partial_0$, $P_j = -i\partial_j$, $j = 1, 2, 3$, is defined by

$$P_\mu|k_0, k_1, k_2, k_3> = k_\mu|k_0, k_1, k_2, k_3>,$$

$$<k_0, k_1, k_2, k_3|t, x, y, z> = e^{i(k_\mu x^\mu)}(2\pi N)^2. \quad N \in \mathbb{R}. \quad (21)$$

Also the curve space-time coordinates operators are given by $\hat{X}^\mu = (i\hat{X}, \hat{Y}, \hat{Z})$ and conjugate momentum operators $P_\mu = (P_0, P_1, P_2, P_3)$ such that $P_0 = ig_{00}\partial_0$ and $P_j = ig_{jj}\partial_j$, $j = 1, 2, 3$.

In the path integral point of view, the action (7) gives the transition amplitude of the model (or the partition function $Z(A, \Gamma) = \mathcal{N}\int D\psi D\bar{\psi} e^{iS}$) which is explicitly written as:

$$Z(A, \Gamma) = \exp \left[ -\text{Tr} \ln \frac{i\gamma^\mu \partial_\mu - m + i\epsilon}{\mathcal{M}} \right], \quad (22)$$

with $\mathcal{M} = i\gamma^\mu (\partial_\mu - \Gamma_\mu + iA_\mu) - m + i\epsilon$ and the normalization constant is defined such that $Z(0, 0) = 1$. Using the following identities:

$$C_\mu C^{-1} = -\gamma^\mu, \quad (\gamma^\mu)^\dagger = -e^{i\epsilon}C^\mu C^{-1} = -C_\mu C^{-1}, \quad \Gamma_\mu = -i\Gamma C^{-1}, \quad \text{we come to } \mathcal{M} = iC_\mu C^{-1}(\partial_\mu - iA_\mu)C^{-1} - m + i\epsilon$$

and the conjugate of the functional $Z(A, \Gamma)$ is given by

$$Z^*(A, \Gamma) = \exp \left[ -\text{Tr} \ln \frac{iC^\mu C^{-1}\partial_\mu + m + i\epsilon}{\mathcal{M}} \right], \quad (23)$$

where $C = i\gamma^2\gamma^0$.

We now compute the transition amplitude $|Z(A, \Gamma)|^2$. For this, let us define the quantities $X_H(\omega, 0) = \omega X_H, \quad X_H(\omega, 0) = \omega X_H^0, \quad Y_H(\omega, 0, E, B) = \omega Y_H, \quad Y_H(\omega, 0, E, B) = \omega Y_H^0$, such that

$$X_H^0 = 2t|P|^2 + \gamma^0\gamma^1 P_1 + \gamma^0\gamma^2 P_2 + \gamma^0\gamma^3 P_3, \quad (24)$$

$$X_H^2 = 2X|P|^2 + \gamma^0\gamma^1 P_0 + i\gamma^1\gamma^2 P_2 + i\gamma^1\gamma^3 P_3, \quad (25)$$

$$Y_H^0 = 2t|P|^2 + 4\gamma^0\gamma^1 P_1 + (4\gamma^0\gamma^2 + 4BXt)P_2$$

$$+ (4\gamma^0\gamma^3 - 4Et^2)P_3 - 6\gamma^0\gamma^3 Et + 4\gamma^0\gamma^2 BX + 2i\gamma^1\gamma^2 Bt + 2t(B^2X^2 + E^2t^2), \quad (26)$$

$$Y_H^2 = 2X|P|^2 - 2\gamma^1\gamma^0 P_0 + (2\gamma^1\gamma^2 + 4BX^2)P_3 + (2\gamma^1\gamma^3 - 4EXt)P_3 - i\gamma^1\gamma^3 Et + 3i\gamma^1\gamma^2 BX - 2\gamma^0\gamma^3 EX + 2X(B^2X^2 + E^2t^2). \quad (27)$$

Then $P = |Z(A, \Gamma)|^2$ is explicitly written as

$$P = \exp \left[ -\text{Tr} \ln \frac{\ell(\omega, \bar{\omega})}{n(\omega, \bar{\omega}, E, B)} \right]$$

$$= \exp \left[ -\text{Tr} \int_0^\infty \frac{ds}{s} \left( e^{isn(\omega, \bar{\omega}, E, B)} - e^{is\ell(\omega, \bar{\omega})} \right) \right] \quad (28)$$

where

$$\ell(\omega, \bar{\omega}) = X_H(0, 0) + X_H(\omega, 0) + X_H(0, \bar{\omega})$$

$$n(\omega, \bar{\omega}, E, B) = Y_H(0, 0, E, B) + Y_H(\omega, 0, E, B) + Y_H(0, \bar{\omega}, E, B). \quad (29)$$

We get the following statement:

**Proposition 2.** Consider that the EM fields are vanishing. For very small positif parameter $\epsilon$ of the size $1/\omega^2$, the probability of the pair production takes the form

$$P = \exp \left\{ -\pi \text{e}^{*}m^8 \frac{37}{1024\epsilon} \right\}, \quad (31)$$

where $\omega = v\bar{\omega}$, $a = \frac{3\pi}{8\omega}(v^2 + 1)$, $b = \frac{3\pi}{2\omega}(4v^2 + 1)$, $N_\gamma$ is the Euler number, $M = \int \mu(y, z)dydz$, and $\mu(y, z)$ is the test function.

**Remark 1.** Note that the case where $M > 0$ is not fulfilled. This leads to an infinite probability density. We choose the test function $\mu(y, z)$ such that $M < 0$, and then

$$\pi \frac{e^m m^8}{1024} \left[ 2N_\gamma - \frac{37}{12} \left( 4 \ln b - \ln a \right) \right] > 0. \quad (33)$$

In the figure (1) we give the plot of this probability density as function of the parameter $\epsilon$. This figure gives asymptotically the values of $f(\epsilon) = P$ when $\epsilon$ tends to zero. Then the limit $\epsilon \rightarrow 0$ leads to $P \approx 0$.

**Proof.** of the proposition (2). The rest of this section is devoted to the proof of the proposition (2). The density $\Omega = \Omega(\omega, \bar{\omega}, E, B)\mathcal{F}$ such that $\mathcal{P} = \exp(-\Omega)$ can be expanded as

$$\Omega = \Omega(1, \omega, \bar{\omega}, E, B) - \Omega(2, \omega, \bar{\omega}, E, B), \quad (32)$$

where

$$\Omega_1 = \int dx \int_0^\infty \frac{ds}{s} \langle x | e^{isY_H(\omega, \bar{\omega}, E, B)} | x \rangle, \quad (33)$$
Now we choose $\omega_1$ and $\omega, \omega_2$.

FIG. 1: Plot of $P = f(\epsilon)$ with $v = 1, M = -2\pi, m = 1, \omega = \sqrt{\epsilon}$.

$$\Omega_2 = \int dx \int_0^\infty \frac{ds}{s} \langle x | e^{i\omega_2 H_0} | x \rangle. \quad (34)$$

We consider the mean values:

$$x_H^1 = < x | X_H^1 | x >, \quad x_H^2 = < x | X_H^2 | x >, \quad y_H^1 = < x | Y_H^1 | x >, \quad y_H^2 = < x | Y_H^2 | x >. \quad (35)$$

Now we choose $\omega = v\tilde{\omega}$ and $vt + x > 0$ and we are focussing on the computation of $\Omega_1(\omega, \tilde{\omega}, E, B)$. We get

$$\Omega_1 = \int_0^\infty \frac{ds}{s} \langle x | e^{i\omega H(0, 0, E, B)} | x \rangle \times \int dx dk \left( 1 + is\omega y_H^1 + is\tilde{\omega} y_H^2 \right) \quad (36)$$

with

$$\langle x | e^{i\omega H} | x \rangle = \frac{-iEB \coth(Es) \cot(Bs)}{4\pi^2} e^{-ism^2}. \quad (37)$$

A simple routine checking shows that

$$\int dx dk \exp \left[ i\tilde{\omega} \left( vy_H^1 + y_H^2 \right) \right] = \frac{M \pi^2 e^\pi}{4s^2} \int \frac{dx dt}{(vt + x)^2} \left\{ \exp \left[ i\tilde{\omega} \left( \frac{P(x, t)}{vt + x} + Q(x, t) \right) \right] \right\} \quad (38)$$

with

$$P(x, t) = 2v^3 (3 + 2B x t)^0 x^2 + B^2 x^2 t^2 - 2\gamma_0^0 \gamma_2 E_t + E_t^2 + 2v(2B x^2 - 2\gamma_0^0 \gamma_2 E_t + 2B x^2) \gamma_0^3 E_t - 2\gamma_0^1 \gamma_2 E_t + E_t^2 + 2\gamma_0^1 \gamma_2 E_t E_t^2 + 2B^2 x^4 - 2\gamma_0^1 \gamma_3 E_t + 2E_t^3 t^2, \quad (39)$$

and

$$Q(x, t) = v^3 [4\gamma_0^0 \gamma_2 B x - 6\gamma_0^0 \gamma_3 E_t + 2\gamma_0^1 \gamma_2 B t + 2t(B^2 x^2 + E_t^2)] - i\gamma_0^1 \gamma_3 E_t + 3\gamma_0^1 \gamma_2 B x - 2\gamma_0^0 \gamma_3 E_t + 2B^2 x^2 + 2E_t^3 t^2. \quad (40)$$

In the same manner $\Omega_2$ takes the form

$$\Omega_2 = \int_0^\infty \frac{ds}{s} \int dx dk \langle x | e^{i\omega_2 H(0, 0)} | x \rangle \times \left( 1 + is\omega x_H^1 + is\tilde{\omega} x_H^2 \right) \quad (41)$$

where

$$\langle x | e^{i\omega H} | x \rangle = -\frac{i}{16\pi^2 s^2} e^{-ism^2}. \quad (42)$$

We can now show that

$$\int dx dk \left( 1 + is\tilde{\omega} x_H^1 + is\tilde{\omega} x_H^2 \right) = \int dx \frac{\pi^2 e^\pi}{4s^2 (vt + x)^2} \exp \left[ -\frac{3i\tilde{\omega}(v^2 + 1)}{8(vt + x)} \right]. \quad (43)$$

However

$$\Omega(\tilde{\omega}, E, B) = \frac{iMe^\pi}{64\pi} \int_0^\infty ds e^{-ism^2} \frac{1}{s^2} I(t_0, x_0) \quad (44)$$

where $M$ is chosen to be $M = \int \mu(x, y) dy dz < \infty$,

$$I(t_0, x_0) = \int_{t_0}^{\infty} \int_{t_0}^{\infty} dx dt \frac{\pi^2 e^\pi}{4s^2 (vt + x)^2} \left\{ \exp \left[ -\frac{3i\tilde{\omega}(v^2 + 1)}{8(vt + x)} \right] \right\} \quad (45)$$

and

$$J(t_0, x_0) = \int_{t_0}^{\infty} \int_{t_0}^{\infty} dx dt \frac{1}{(vt + x)^2} \times \exp \left[ i\tilde{\omega} \left( \frac{P(x, t)}{vt + x} + Q(x, t) \right) \right]. \quad (46)$$

The integral (44) exhibit the divergence at point $x = t = 0$. This shall be regularized by using the Cauchy principal value. For $E = B = 0$ we get

$$I(0, 0) = \frac{1}{\alpha_1} \int_0^{\infty} dt \left[ \sin(\alpha_1/\nu t) + 2i\sin^2(\alpha_1/2\nu t) \right] = \frac{i\pi}{2\nu} + \frac{1}{\nu} \left[ 1 - N_\gamma - \ln \left( \frac{\alpha_1}{\nu} \right) \right], \quad (47)$$

$$J(0, 0) = \frac{1}{\alpha_2} \int_0^{\infty} dt \left[ \sin(\alpha_2/\nu t) + 2i\sin^2(\alpha_2/2\nu t) \right] = \frac{i\pi}{2\nu} + \frac{1}{\nu} \left[ 1 - N_\gamma - \ln \left( \frac{\alpha_2}{\nu} \right) \right], \quad (48)$$

with $\alpha_1 = \frac{3i\tilde{\omega}(v^2 + 1)}{8}, \alpha_2 = \frac{3i\tilde{\omega}(2v^2 + 3)}{8}$ and $N_\gamma$ is the Euler number given by $N_\gamma = 0.577215664$. Also, for $a, b \in \mathbb{R}$ the integral

$$Q = \int_0^\infty ds \frac{e^{-ism^2}}{s^3} \left( 4\ln(b) - \ln(a) \right)
in the limit

Remark that the probability density of pair creation

\[ \Omega(0, E, B) = \frac{EB}{4\pi^2} \sum_{k=1}^{\infty} \frac{1}{k} \coth \left( k\pi \frac{B}{E} \right) \exp \left( -k\pi m^2 \right). \]  

(50)

Using the Taylor expansion as

\[ \Omega(\omega, E, B) = \Omega(0, E, B) + \omega \Omega'(0, E, B) + O(\omega^2), \]  

(51)

we come to \(\Omega(\omega, 0, 0) = \omega \Omega'(0, 0, 0) + O(\omega^2)\)

\[ \Omega(\omega, 0, 0) = \frac{iMe^\pi}{64e} \int_0^\infty ds \frac{e^{-ism^2}}{s^5} \mathcal{T}(0, 0), \]  

(52)

\[ \mathcal{T}(0, 0) = \mathcal{T}(0, 0) - 4\mathcal{J}(0, 0). \]

We choose the real part of \(\Omega(\omega, 0, 0)\) denoted by \(\Re_0 \Omega(\omega, 0, 0) = [\Omega(\omega, 0, 0) + \Omega^*(\omega, 0, 0)]/2\). Using (47), (48) and (49)

\[ \Re_0 \Omega(\omega, 0, 0) = \frac{\pi M e^\pi m^8}{1024\sqrt{e}} \left[ 2N_\gamma - \frac{37}{12} \right] \]  

\[ - \frac{1}{3} \left( 4\ln b - \ln a \right) \]  

(53)

where \(a = \frac{3\omega}{8e} (v^2 + 1)\), \(b = \frac{3\omega}{8e} (4v^2 + 1)\). Finally it is straightforward to check the following relation

\[ \tilde{\omega} \Omega'(0, 0, 0) = \frac{\pi Me^\pi m^8}{1024\sqrt{e}} \left[ 2N_\gamma - \frac{37}{12} \right] \]  

\[ - \frac{1}{3} \left( 4\ln b - \ln a \right) \]  

(54)

While the probability of the pair production takes the form

\[ \mathcal{P} = \exp \left\{ -\frac{\pi Me^\pi m^8}{1024\sqrt{e}} \left[ 2N_\gamma - \frac{37}{12} \right] \right\} \approx 0. \]  

(55)

This end the proof of proposition (2).  \(\square\)

IV. SOLUTION OF THE DIRAC EQUATION

In this section we give the solution of the Dirac equation (12). We consider the operators \(K_1\) and \(K_2\) satisfying the commutation relation \([K_1, K_2] = 0\) and given by

\[ K_1 = i\gamma^0 \partial_0 - i\gamma^2 k_2 - i\gamma^3 k_3 + i\gamma^3 E t + 9i\omega \gamma^0 - 3\omega_1 - m(1 - \omega t), \]  

(56)

\[ K_2 = -\gamma^1 \partial_1 - i\gamma^2 Bx + m\omega x. \]  

(57)

The equation (12) takes the form \((K_1 + K_2)\psi(t, x) = 0\) and admit separate variables as \(\psi(t, x) = \psi(t)\psi(x)\). For a constant \(\lambda \in \mathbb{C}\), we get the two eigenvalue equations

\[ K_1 \psi(t) = \lambda \psi(t), \]  

(58)

\[ K_2 \psi(t) = \lambda \psi(t), \]  

(59)

Consider the equation (58). We write the four vector \(\psi(t)\) as \(\psi(t) = (\psi_1(t), \psi_2(t))\) and \(\psi_j(t) = (\psi_{ja}(t), \psi_{jb}(t))\), \(j = 1, 2\), and the equation (58) leads to

\[ (L' L + D^2 + CC') \psi_{1a}(t) = 0, \]  

(60)

\[ (LL' + D^2 + CC') \psi_{2a}(t) = 0, \]  

(61)

\[ C \psi_{1b}(t) = L' \psi_{2a}(t) - D \psi_{1a}(t), \]  

(62)

\[ C \psi_{2b}(t) = -L \psi_{1a}(t) - D \psi_{2a}(t) \]  

(63)

where

\[ L = i\partial_0 + 9i\omega - m(1 - \omega t) + \lambda, \]  

\[ L' = -i\partial_0 - 9i\omega + m(1 - \omega t) + \lambda, \]  

\[ C = -3\omega + k_2, \quad C' = -3\omega + k_2, \]  

\[ D = iEt - ik_3. \]

Let

\[ f(t) = \frac{E}{2} t^2 + \left( \frac{m}{E} (m - \lambda) \omega - 9\omega - k_3 \right) t, \]  

(64)

\[ g(t) = (-1)^{\frac{1}{2}} (iE)^{\frac{3}{2}} t \]  

(65)

\[ \delta_k^1 = \frac{m\omega}{2\sqrt{E}} (m - \lambda) \]  

\[ + \frac{1}{2} \left( k_2^2 - (m - \lambda)^2 + im\omega \right) - \frac{1}{2}, \]  

(66)

\[ \delta_k^2 = \frac{(-1)^{\frac{1}{2}}}{(iE)^{\frac{3}{2}}} (E k_3 - (m - \lambda)m\omega). \]  

(67)

The solution of the equations (66) are a linear combination of Hermite and (1,1)-hypergeometric polynomial given by

\[ \psi_{1a}(t) = c_1 e^{f(t)} \mathcal{H} \left[ \delta_k^1, \delta_k^2 + g(t) \right] \]
However, the equation (72) can be split into

\[ \psi_{2a}(t) = c_1 e^{\int_0^t H(\kappa, \frac{1}{2}, 3 (\delta_{E} + g(t))^2) dt} \]

\[ + c_2 e^{\int_0^t H(\kappa, \frac{1}{2}, 3 (\delta_{E} + g(t))^2) dt} \]

the solutions of the equation (62) can be simple obtained using the followings identities:

\[ \frac{d \mathcal{H}(a, b + ct)}{dt} = 2ac \mathcal{H}(-1 + a, b + ct), \]

\[ \frac{d_1 F_1(a, b, ct^2 + dt + e)}{dt} = \frac{a(d + 2ct)}{b} F_1(1 + a, 1 + b, ct^2 + dt + e) \]

Now, consider the equation (59). Using the Dirac matrices (6), we get

\[ - (\sigma_1 \partial_t + i\sigma_2 Bx) \psi_2(x) \right) + (m \bar{\omega}x - \lambda) \psi_2(x) = 0 \]

\[ (\sigma_1 \partial_t + i\sigma_2 Bx) \psi_1(x) \right) + (m \bar{\omega}x - \lambda) \psi_2(x) = 0 \]

where \( \psi(x) = (\psi_1(x), \psi_2(x)) \). Let us define the quantities \( b(B), r(B) \) and \( s(B) \) as

\[ b(B) = \frac{\lambda^2}{2B} \]

\[ r(B) = \frac{2m \bar{\omega} \lambda (-1) \frac{i}{2}}{\sqrt{2}(iB)^{\frac{1}{2}}} \]

\[ s(B) = (-1) \frac{i}{2} \sqrt{2}(iB)^{\frac{1}{2}} \]

For \( \psi_j(x) = (\psi_{ja}(x), \psi_{jb}(x)) \), \( j = 1, 2 \). The solutions of the equation (71) are

\[ \psi_{1a}(x) = c_1 D \left( -b(B), -r(B) + s(B)x \right) \]

\[ + c_2 D \left( -b(B), -ir(B) + is(B)x \right) \]

\[ \psi_{1b}(x) = c_1 D \left( -1 - b(B), -r(B) + s(B)x \right) \]

\[ + c_2 D \left( -1 - b(B), -ir(B) + is(B)x \right) \]

However, the equation (72) can be split into

\[ \left[ \partial^2 - B - B^2 x^2 + \lambda^2 - 2m \bar{\omega}x \right] \psi_{1a}(x) = 0 \]

\[ \left[ \partial^2 + B - B^2 x^2 + \lambda^2 - 2m \bar{\omega}x \right] \psi_{1b}(x) = 0 \]

and the solutions are well given by the following:

\[ \psi_{2a}(x) = \frac{1}{\lambda - m \bar{\omega}x} (\partial_1 + Bx) \psi_{1b}, \]

\[ \psi_{2b}(x) = \frac{1}{\lambda - m \bar{\omega}x} (\partial_1 - Bx) \psi_{1a}. \]

where the identities

\[ \frac{d}{dx} D(a, bx + c) = \frac{b}{2} (bx + c) D(a, bx + c) \]

are useful.

V. CONCLUSION

In this paper, we have computed the probability density of pair production of the fermion particles. The case of vanishing EM fields is scrutinized explicitly. Hereafter we will shed light on the case of non-vanishing EM fields, which has not been entirely considered in this paper. In the other hand, we have solved the Dirac equation coupled with gravitation field, using the separation of variables. The solutions are expressed in terms of hypergeometric functions. The limit where the deformation parameter \( \bar{\omega} \) tends to zero is given.
