Abstract

BACKGROUND: Diabetes mellitus (DM) is a group of metabolic diseases indicated by hyperglycemia. Dietary regulation represents a viable means of controlling blood glucose levels. Porang (Amorphophallus oncophyllus) is a local tuber that has a low glycemic index due to its high glucomannan content. In combination with Strobilanthes crispus (SC), which is rich in antioxidants, porang flour could be a promising treatment approach for DM.

AIM: This study aimed to determine the effect of porang flour macerated with SC on the blood glucose levels of diabetic rats.

METHODS: Thirty-five Wistar (Rattus norvegicus) rats were divided into five groups on the basis of their diets: Normal/negative control (NC) group (non-diabetic, standard AIN-93 diet), positive control (PC) group (streptozotocin [STZ]-induced diabetic, glibenclamide [GB] group (STZ-induced diabetic, medicated with GB 100 mg/200 g body weight [BW]), porang (NP) group (modified AIN-93 diet, fiber substituted with 11% porang flour [equal to 1.1 g/200 g BW]), and SC-macerated porang (SP) group (modified AIN-93 diet, fiber substituted with 11% porang flour macerated with SC [equal to 1.1 g/200 g BW]). The rats’ food intakes, stools, and BWs were recorded throughout the study, while their blood glucose levels were measured before the induction of DM, 3 days after the induction of DM, and at the end of the study (14-day treatment period). The data were statistically analyzed using a one-way analysis of variance combined with Duncan’s multiple range test.

RESULTS: The rats’ feed intakes during the 14-day treatment period were almost the same, which influenced their BWs. After the induction of DM, the rats’ BWs appeared to decrease, albeit not to a statistically significant extent. This weight loss may have been better controlled in the treatment groups because the glucomannan content of the porang led to an improvement in the rats’ glucose metabolism, especially in the NP and SP groups. The rats’ stools appeared normal in consistency and moisture, and it was confirmed that there were no diarrhea incidents. The glucomannan content also decreased the blood glucose levels in the NP and SP groups. The SP group showed the best results in terms of decreased glucose levels due to the addition of SC as a source of antioxidants.

CONCLUSION: Porang exerted an antidiabetic effect that was comparable with the effect of GB (a commercial drug). In combination with SC, it provided a high level of antioxidants. Porang should be further studied to optimize its antidiabetic potency and potential for use as a functional food or nutraceutical.

Introduction

Diabetes mellitus (DM) is a group of metabolic diseases associated with insulin function or secretion disorder and indicated by hyperglycemia [1, 2]. The negative impact of DM is known to result in comorbidities such as multiple secondary micro- and macro-vascular complications and neuropathic disorders [3]. If DM is not taken seriously, it may lead to a significant decrease in quality of life as well as an increase in health-related costs.

In addition to the use of hypoglycemic drugs, dietary regulation represents a means by which patients can control their blood glucose levels. A diet that is rich in foods that have a low glycemic index can have a positive effect in terms of lowering blood glucose levels [4]. Porang (Amorphophallus oncophyllus) is a kind of konjac tuber that is widely cultivated in Indonesia. It has a low glycemic index [5] due to its high glucomannan content. Various studies concerning the health effects [6], [7] and applications of porang have been conducted [8], [9], [10], [11], [12], [13], [14], although the use of raw porang flour remains rare due to the limited availability of calcium-oxalate-free flour.

Porang flour macerated with Strobilanthes crispus (SC) has previously been studied with regard to its safety [15] and low calcium oxalate content [16]. The SC content of porang, which is rich in flavonoid and phenolic acid [17], has shown potential in relation to the
treatment of DM. However, its potency has not yet been adequately studied. The aim of the present study was to determine the effect of porang flour macerated with SC on the blood glucose levels of diabetic rats.

Methods

Plant material

The porang tubers used in this study were obtained from a farmer in Madiun, East Java. The tubers were cleaned of sand, sliced, and dried. They were then ground and sifted through a 40-mesh sieve to make powder/fLOUR. Next, the flour was macerated with SC, as described in Patent Application No. S00202006688 [16].

Experimental animals

The present study was conducted in accordance with the requirements of the Health Research Ethics Committee of Universitas Alma Ata (reference no. KE/AA/VII/273/EC/2017). Thirty-five Wistar (Rattus norvegicus) rats that were 8 weeks of age and had body weights (BWVs) of 121–159 g were used in this study. The rats were divided into five groups on the basis of their diets. Each control group was fed with a standard AIN-93 diet [18]: NC group (normal/negative control [NC], non-diabetic), PC group (positive control [PC], streptozotocin [STZ]-induced diabetic), and glibenclamide (GB) group (STZ-induced diabetic, medicated with GB 100 mg/200 g BW). The two treatment groups were fed with a modified AIN-93 diet, in which the fiber was substituted with 11% (equal to 1.1 g/200 g BW) porang (NP group) or SC-macerated porang (SP group). The rats were individually housed in wire cages at an ambient temperature with a 12-h light-dark cycle. Their food intakes, stools, and BWs were recorded throughout the study, while their blood glucose levels were measured before the induction of DM, 3 days after the induction of DM, and at the end of the study (14-day treatment period).

Induction of diabetes, blood preparation, and biochemical analysis

The intraperitoneal injection of nicotinamide (110 mg/kg BW) was performed before the induction of DM with 8 mg/200 g BW of STZ. The rats were categorized as diabetic when their blood glucose level was more than 126 mg/dL [1]. The blood glucose levels were determined from plasma samples by means of the glucose oxidase–peroxidase aminoantypirin enzymatic method. The plasma was prepared through the centrifugation of blood samples (at 400 rpm for 15 min) that had been drawn from the vena retro-orbital sinus using the microcapillary technique.

Statistical analysis

All data were presented as the mean ± standard deviation. A one-way analysis of variance combined with Duncan’s multiple range test at p < 0.05 was used to compare the data among the groups. A paired T-test analysis was also used to compare the data from before and after the treatment. All the analyses were performed using the Statistical Package for the Social Sciences (SPSS) software (version 16.0; SPSS Inc., Chicago, USA).

Results

Feed intake, BW of rat, and observation of stools

Feed intake, BW, and stool observation of rats during 14 days of treatment periods are shown in Table 1. The intake of rats was almost the same between groups, in the range of 8.84–9.64 g, except NC group. Normal group had significantly lower feed intake than diabetic groups (p < 0.05). Feed intake relates to the BW of rats. During 14 days of the treatment, the BW of rats seemed down, but not statistically different (p > 0.05). The observation of stools showed that the stools in all groups were in normal moisture and consistency.

Blood glucose levels

Table 2 showed blood glucose levels of rats before and after STZ induction and also after 14 days of treatments. The initial blood glucose levels of rats were in the range of 50–135 mg/dL and increased to 217–244 mg/dL after STZ induction. The different intervention between groups gave the different impact on the blood glucose value. The intervention of commercial drug (GB group) and porang flour (NP and SP groups) significantly decreased blood glucose levels (p < 0.05), while PC group showed almost the same value compared to before intervention.

Table 1: Feed intake, body weight, and stool character of rats during 14 day of treatment periods

| Groups | Feed intake (g) | Stools character | Body weight (g) | ∆K |
|--------|----------------|------------------|----------------|----|
|        |                 | Water content (%) | Consistency     | Before intervention | After intervention |    |
| NC     | 6.18 ± 0.8³a   | 39.40 ± 2.2²a    | Slightly hard   | 133.2 ± 7.3       | 130.4 ± 13.0       | –2.8³ |
| PC     | 9.56 ± 1.1¹    | 76.20 ± 5.3³     | Soft           | 134.4 ± 11.8      | 123.4 ± 13.8       | –11.0¹ |
| GB     | 9.56 ± 1.9³a   | 71.40 ± 3.0³     | Soft           | 141.2 ± 9.9       | 133.0 ± 10.3       | –8.2² |

| SP     | 8.84 ± 1.9²a   | 70.20 ± 2.8²     | Soft           | 138.8 ± 13.4      | 132.80 ± 4.1       | –6.0² |

¹Different superscript letter in the same columns indicated significantly different result (p<0.05). NC group (normal/NC, non-diabetic, AIN-93 diets), PC group (PC, STZ-induced diabetic, AIN-93 diets), GB group (STZ-induced diabetic, AIN-93 diets, medicated with GB), NP group (STZ-induced diabetic, AIN-93 modified diets with 11% porang flour), and SP group (STZ-induced diabetic, AIN-93 modified diets with 11% SP flour).
### Table 2: Blood glucose levels of rats in various treatment during 14 days of treatment

| Groups | Blood glucose levels (mg/dL) | Before STZ induction | After STZ induction | After intervention | ΔX |
|--------|-----------------------------|----------------------|---------------------|-------------------|-----|
| NC     | 69.6 ± 0.9*                 | 67.17 ± 1.4          | 67.4 ± 2.0          | 0.67*             |
| PC     | 66.7 ± 1.1                  | 244.4 ± 7.4          | 215.7 ± 6.1         | 1.26*             |
| GB     | 70.4 ± 2.3                  | 217.40 ± 7.8         | 121.8 ± 5.3         | -96.6*            |
| NP     | 68.3 ± 1.11*                | 217.4 ± 9.2          | 156.8 ± 4.3         | -62.9*            |
| SP     | 68.7 ± 1.99*                | 224.5 ± 7.3          | 133.2 ± 1.9         | -91.3*            |

*Different superscript letter in the same columns indicated significantly different result (p<0.05). ΔX showed the different value between 0 and 14 using t-test. NC group (normal; normal blood glucose), PC group (PC: STZ-induced diabetic; AIN-93 diet). GB group (STZ-induced diabetic; AIN-93 diet, medicated with GB), NP group (STZ-induced diabetic; AIN-93 modified diet with 11% porang flour), and SP group (STZ-induced diabetic; AIN-93 modified diet with 11% SP flour).

### Discussion

#### Feed intake, BW of rat, and observation of stools

Feed intake of rats during 14 d of treatment periods is shown in Table 1. The amount of intake was almost the same between groups, NC showed the lowest amount of feed intake and was statistically different from others (p < 0.05). It may be due to NC rats’ behavior that looked more active than other groups. It caused some feeds were fallen or be mixed in the drinking water so that could not be weighed. The feed intake of NC was also statistically different with PC (p < 0.05). It indicated that the inducement of diabetes influenced the feed intake or rat’s appetite.

The BW of rats during the study is shown in Table 1. After 14 days of treatment, the BW of rats was not statistically different (p > 0.05), but there was weight loss after STZ induction that may be caused by insufficient insulin. It led to an inability of glucose to be used as energy; therefore, the availability in the body was provided by fat catabolism. If it was happened continuously, it could lose the BW [19], [20], [21]. However, the BW in treatment groups (GB, NP, and SP) could be controlled by increasing the insulin sensitivity resulting in the improvement of glucose metabolism [22] for GB groups or by the role of glucomannan as fiber in NP and SP groups that fulfilled the intestine and decrease the feed intake [6], [23]. It may also decrease postprandial glucose and improve insulin sensitivity [24], [25]. The previous study has also been studied for the potency of porang glucomannan as a prebiotic that increased short-chain fatty acid in the colon [6], leading to the improvement of glucose and lipid metabolism [23], [26] and resulting in controlling of BW [24].

The inability of BW to increase in this study was also confirmed by the observation of stools that are shown in Table 1, especially to know whether there was diarrhea or other disorder in gastrointestinal. The data showed that stools in all groups were in normal moisture and consistency. It meant that there was no diarrhea, instead, there were also no difficulties in defecating process. The previous study proved that glucomannan absorbed much water and influenced the dry and wet stool weight, the defecation frequency, and colonic flora in stool [27]. The porang consumption and its combination with SC did not affect the gastrointestinal response.

### Blood glucose levels

Table 2 showed that the initial blood glucose levels were in the range of 50–135 mg/dL. It meant that all intervention groups were normal. The measurement of initial blood glucose levels of rats aimed to ensure that the rats was in normal condition. After being induced with STZ, blood glucose levels in diabetic groups increased in the range value between 217 and 244 mg/dL. The rats with blood glucose levels more than 126 mg/dL were included in diabetic groups [1]. STZ-induced diabetes by damaging β-cells through the production of radicals NO that may block the Fe-containing enzymes and the breakdown of secondary radicals caused peroxide of lipids, reduced antioxidant, and led to DNA damage [28], [29].

The intervention of commercial drug (GB group) and porang flour (NP and SP) significantly decreased blood glucose levels (p < 0.05), although they were still above 126 mg/dL, especially for NP and SP (Table 2). GB worked by stimulating the insulin secretion in the pancreas gland through sensitizing of β-cells allowing glucose-induced changes in the synthesis and release of insulin [22]. NP and SP worked as the fiber that has high water absorption and is very viscous [6] that may decrease food absorption in the small intestine and decrease postprandial glucose and insulin secretion leads to the improvement of insulin sensitivity [24], [25]. This was also confirmed by the histopathological study of the pancreas that showed the maintaining of pancreatic structure in diabetic rats treated by konjac glucomannan [24].

This study also presented that SP groups had a similar antihyperglycemic ability with GB. The role of fiber in porang was strengthened by the existence of SC. SC is the source of flavonoids and phenolic acids that possessed anti-diabetic activity in diabetic rats [17]. SC was also useful in decreasing calcium oxalate in porang and had no acute toxicity result [15] which allows its use as a functional food.

### Conclusion

This study concluded that porang had anti-diabetic capacity. This capacity was forced by the presence of SC and proved the comparable result with the GB as a commercial drug. Further study is needed in the optimization of doses to improve the anti-diabetic capacity and probability uses as functional food or nutraceuticals.
