Cyclopeptide Derivatives from the Sponge-Derived Fungus Acremonium persicinum F10

Yingxin Li and Zhiyong Li *

Abstract: Cyclopeptides usually play a pivotal role, either in the viability or virulence of fungi. Two types of cyclopeptides, six new hydroxamate siderophore cyclohexapeptides (1–6), including acromonpeptides E and F, and their complexes with aluminum and ferric ions; one new cyclic pentapeptolide, aselacin D (9); together with a known compound, aselacin C (10), were isolated and characterized from the sponge-derived fungus Acremonium persicinum F10. In addition, two new siderophore analogues chelating gallium ions (Ga^{3+}), Ga (III)-acromonpeptide E (7) and Ga (III)-acromonpeptide F (8), using isolated acromonpeptides E and F, were prepared. The planar structures of 1–10 were elucidated by HRESIMS and (1D and 2D) NMR. The absolute configurations of amino acids were determined by means of the advanced Marfey’s method and X-ray single-crystal diffraction analysis. X-ray fluorescence (XRF) spectrometer was performed to disclose the elements of compound 1, indicating the existence of aluminum (Al). Al (III)-acromonpeptides E (1), Ga (III)-acromonpeptides E (5), Al (III)-acromonpeptide F (7), and Ga (III)-acromonpeptide F (8) displayed high in vitro anti-fungal activities, which are comparable to amphotericin B, against Aspergillus fumigatus and Aspergillus niger.

Keywords: Acremonium persicinum; cyclopeptides; siderophore; acromonpeptides; marine sponge-derived fungus; anti-fungal activity

1. Introduction

Siderophores from bacteria, fungi, and plants [1,2], assembled by non-ribosomal peptide synthetases (NRPSs), are high-affinity iron chelators responsible for iron acquisition and storage. Siderophores usually provide a “Trojan horse” strategy for humans to exploit new antibiotics using a combination a transporter and antibacterial or bactericidal moieties, such as cefiderocol, the recent Food and Drug Administration (FDA)-approved siderophore-conjugated antibiotic [3]. Hydroxamate-based peptidyl siderophores are the major type in fungi, including the extracellular siderophore, the depsipeptides and coprogen family, and the intracellular siderophore, the ferrichrome family, which enable the uptake of iron from surrounding environment [4]. Among them, ASP2397, a previously reported hydroxamate-based peptidyl siderophore, is a novel natural compound from Acremonium persicinum MF-347833, exhibiting potent fungicidal activity against the invasive Aspergillus genus with unique bacteriostatic mechanism [5,6]. Eight naturally occurring derivatives of ASP2397 have been isolated from Acremonium persicinum (Figure S1), some of which exhibit antifungal and antiviral activities, indicating their potentials as drug leads [5,7].

Marine-derived fungi are valuable resources for the exploration of structurally novel and bioactive compounds and drug leads [8–11]. In particular, chemical studies of marine sponge-derived fungi have afforded a variety of bioactive secondary metabolites [12–14]. Here, we report seven new cyclopeptide compounds from Acremonium persicinum F10 derived from marine sponge Phakellia fisca in the South China Sea.

Originally, sponge-derived fungal strains were screened by adopting the OSMAC (one strain many compounds) approach; as a result, we found that Acremonium persicinum F10...
displayed the richest metabolites in the HPLC chemical profiles when statically cultured on rice medium. Consequently, three new cyclopeptide compounds (2, 4, 9), four Al$^{3+}$ and Fe$^{3+}$ complexes of 2 and 4, and a known compound 10 were isolated by scale-up fermentation of A. persicinum F10. In addition, two new chelates (compounds 7 and 8) with Ga$^{3+}$ were synthesized in vitro by two new ligands (compounds 2 and 4) (Figure 1). Compounds 1, 5, 7, and 8 exhibited excellent anti-fungal activities, comparable with positive control amphotericin B (Minimum Inhibitory Concentration, MIC at 1 µM). Meanwhile, all these compounds showed no cytotoxicity to normal cell (human embryonic lung fibroblast, MRC-5) at the concentration of 30 µM.

2. Results and Discussion
2.1. Structure Elucidation of Compounds 1–10

Al (III)-acremonpeptide E (1) was isolated as a white needle-like crystal. The molecular formulation was unable to be deduced by element composition of C, H, O, N, or S from the HRESIMS data $m/z$ 872.4123 [M + H]$^+$. X-ray fluorescence (XRF) spectrometry was performed to check the elements of compound 1, and the existence of aluminum (Al) in 1 was confirmed by comparing with the control (Figure S2).

The molecular formula of 1 was finally deduced as C$_{39}$H$_{58}$N$_{9}$O$_{12}$Al (Calcd. for C$_{39}$H$_{58}$N$_{9}$O$_{12}$Al, $m/z$ 872.4099 [M + H]$^+$). The 1H and 13C spectra (Table 1) displayed resonances for six NH doublets ($\delta_H$ 10.10, 8.95, 8.44, 8.27, 7.49, and 6.28), six $\alpha$-H ($\delta_H$ 3.87-4.79), nine carbonyls ($\delta_C$ 174.6, 172.3, 171.1, 169.6, 169.4, 169.1, 161.7, 161.5, and 161.4), together with six $\alpha$-methylene carbon signals at 57.9, 55.7, 53.8, 52.5, 52.2, and 46.7, indicating at least six amino acid residues in compound 1. A detailed analysis of the total correlation spectroscopy (TOCSY), heteronuclear single quantum coherence (HSQC), and heteronuclear multiple-bond correlation (HMBC) data allowed for the construction of an alanine (Ala), a leucine (Leu), a phenylalanine (Phe), and three ornithine (Orn) residues (Figure 2). HMBC correlations of three methyl signals with the remaining three carbonyls ($\delta_H$ 2.05/$\delta_C$ 161.5, $\delta_H$ 2.09/$\delta_C$ 161.7, and $\delta_H$ 2.09/$\delta_C$ 161.3) together with HMBC correlations of the methylenes in the Orn to these
three carboxyls (δ_1H 3.69/δ_C 161.5, δ_1H 4.02/δ_C 161.7, and δ_1H 3.41/δ_C 161.3) indicated that each Orn was modified by one acetyl group via an amide bond. The remaining three oxygens and aluminum were deduced to be located in 5-N atom of Orn to form N^5-acetyl-N^5-hydroxyornithine, then chelating with aluminum by detailed review of the literature concerning related structures [15]. Given that 12 of the 13 degrees of unsaturation were attributed to nine carbonyl carbons and a benzene ring, the absence degree of unsaturation suggest that 1 might be a cyclopeptide. The amino acid sequence in 1 of AcN(OH)Orn^1-AcN(OH)Orn^2-AcN(OH)Orn^3-Ala-Leu-Phe was established by the HMBC correlations of Phe-NH (δ_1H 8.95)/Leu-CO (δ_C 172.3), Leu-NH (δ_1H 8.27)/Ala-CO (δ_C 171.1), Ala-NH (δ_1H 7.49)/AcN(OH)Orn^3-CO (δ_C 169.4), AcN(OH)Orn^3-NH (δ_1H 6.28)/AcN(OH)Orn^2-CO (δ_C 174.6), and AcN(OH)Orn^2-NH (δ_1H 10.10)/AcN(OH)Orn^1-CO (δ_C 169.1), which was further verified by ESI-MS/MS fragments at m/z 700.3237 [M-AcN(OH)Orn-Ala-Leu-Phe + H]^+, m/z 672.3278 [M-AcN(OH)Orn-Ala + H]^+, m/z 516.2032 [M-AcN(OH)Orn-Ala-Leu + H]^+, and m/z 369.1337 [M-AcN(OH)Orn-Ala-Leu-Phe + H]^+ (Figure 2 and Figure S10). The planar structure of 1 was further confirmed by X-ray diffraction analysis with Cu Ka radiation accompanied by the Flack parameter of -0.10 (5), which also determined the absolute configuration assignments of L-Ala, L-Leu, D-Phe, L-Orn^1, L-Orn^2, and L-Orn^3 in 1. Thus, compound 1 was identified and named Al (III)-acremonpeptide E.

Figure 2. Key COSY and HMBC correlations of compounds 1–10.

Acremonpeptide E (2) was obtained as a faint yellow solid with a molecular formula of C_{39}H_{61}N_{9}O_{12}, on the basis of its high resolution electrospray ionization mass spectroscopy (HRESIMS) data, which suggested 14 degrees of unsaturation. Comparison of the ^1H NMR and ^13C NMR data of compound 2 (Table 1) with those of 1 suggested that both compounds shared similar structural features, except obvious shifts of the three acetyl group carbonyls (from δ_C 161.5, 161.7, and 161.3 in 1 to 170.8 in 2) and methyls (from δ_C 15.9, 16.2, and 15.3 in 1 to 20.8 in 2) in AcN(OH)Orn residues, forming overlapped carbons. These similar shifts were also observed in compound Al(III)-acremonpeptide D and acremonpeptide D or compound ASP2397 and AS2488059, indicating compound 2 was the ligand compound of 1 by deleting Al (III). As expected, detailed analysis of its TOCSY correlations allowed for the construction of an alanine (Ala), a leucine (Leu), a phenylalanine (Phe), and three N^5-acetyl-N^5-hydroxyornithines in 2 (Figure 2). Further, the amino acid sequence in 2
of AcN(OH)Orn$_1$-AcN(OH)Orn$_2$-AcN(OH)Orn$_3$-Ala-Leu-Phe was established by the HMBC correlations as described in compound 1. This assignment was also verified by the HRMS/MS fragment ion series at $m/z$ 676.3670 [M-AcN(OH)Orn + H]$^+$, $m/z$ 605.3288 [M-AcN(OH)Orn-Ala + H]$^+$, and $m/z$ 345.1782 [M-AcN(OH)Orn-Ala-Leu-Phe + H]$^+$ (Figure 3 and Figure S21). The absolute configuration of the amino acid residues in 2 was determined using advanced Marfey’s method. The hydrolysate of 2 were derivatized with 1-fluoro-2,4-dinitrophenyl-5-$\gamma$-leucinamide (L-FDLA) and analyzed by ultra performance liquid chromatography mass spectrometric (UPLC–MS). By comparing L-FDLA derivatives of amino acid from compound 2 with standard amino acid, we determined the L-Ala, L-Leu, and D-Phe residues in 2 (Figure S22), identical to compound 1 (Figure S21). The absolute configuration of AcN(OH)Orn units of compound 2 was deduced as the same as that of compound 1 with L-Orn residues, owing to a shared biosynthetic pathway. On the basis of these data, we established the structure of compound 2, which was the ligand compound of 1, acremonopeptide E.

Fe (III)-acremonopeptide E (3), obtained as orange-red acicular crystal, had the HRES-IMS data $m/z$ 901.3745 [M + H]$^+$ and $m/z$ 923.3516 [M + Na]$^+$. The existence of iron in compound 3 was deduced by disturbed $^1$H and $^{13}$C NMR records (Figures S25 and S26) in combination with conjectural molecular formula C$_{39}$H$_{58}$N$_9$O$_{12}$Fe (Calcd. for C$_{39}$H$_{59}$N$_9$O$_{13}$Al, $m/z$ 901.3633 [M + H]$^+$). The same losing fragment AcN(OH)Orn ($m/z$ 172), Ala ($m/z$ 113), and Phe ($m/z$ 113) in HRMS/MS data of compounds 3 and 1 indicated that they may possess the same ligand (Figure 3 and Figure S28). A high-quality crystal of 3 was subjected to single-crystal X-ray diffraction analysis with Cu Ka (Figure 4) (Flack parameter = 0.04 (8)), suggesting the planar structure and absolute configuration of compound 3 were identical to 1, except the substitution of metal ion Al (III) in 1 by Fe (III) in 3. Accordingly, the structure of compound 3, which was named Fe (III)-acremonopeptide E, was corroborated.

The molecular formula of acremonpeptide F (4), a faint yellow solid, was determined as C_{39}H_{56}N_{12}O_{13} by the molecular ion at m/z 864.4471 [M + H]^+ (Calcd. for 864.4467) in the HRESIMS data. The 1H NMR and 13C NMR data of 4 (Table 2) was similar to that of compound 2 (Table 2). Comparing the 1D NMR data of compound 4 with those of 2, we found that the presence of an oxygen methylene group (δH 3.55 and 3.58, δC 61.0) and the absence of a methyl group (δH 1.24, δC 18.1) in 4 was the major difference. Detailed analysis of TOCSY and HMBC correlations demonstrated that the only discrepancy in compound 4 was a Ser residue for the Ala moiety substitution relative to 2, which was supported by the HRESIMS/MS fragments at m/z 692.3599 [M-AcN(OH)Orn + H]^+ and m/z 605.3245 [M-AcN(OH)Orn-Ser + H]^+ (Figure 2, Figure 3, and Figure S38). The amino acid sequence of 4 was confirmed as AcN(OH)Orn-L-Ala-Leu-Phe on the basis of HMBC corrections of Phe-NH (δH 8.87)/Leu-CO (δC 172.2), Leu-NH (δH 7.07)/Ser-CO (δC 169.6), Ser-NH (δH 7.58)/AcN(OH)Orn-CO (δC 171.7), AcN(OH)Orn-NH (δH 8.31)/AcN(OH)Orn-CO (δC 171.7), and AcN(OH)Orn-NH (δH 7.78)/AcN(OH)Orn-CO (δC 171.8) (Figure 2). The absolute configuration of the amino acid residues in 4 was determined to be L-Ser, L-Leu, D-Phe, and three of L-AcN(OH)Orn according to Marfey’s method and a shared biogenesis. Thus, the structure of 4 was established and named acremonpeptide F.

Al (III)-acremonpeptide F (5), obtained as a white solid with an [M+H]^+ ion at m/z 888.4073, had a molecular formula of C_{39}H_{56}N_{12}O_{13}Al (Calcd. for C_{39}H_{56}N_{12}O_{13}Al, m/z 888.4048 [M + H]^+), as designated by the HRESIMS and 13C NMR data. The 1D NMR and 2D NMR spectra indicated that compound 5 possessed a similar structure to compound 4, except that the overlapped carbon signals in 4 were clearly separated in 5 from the 13C NMR, which was also observed between compounds 1 and 2. Therefore, we speculated that 5 was the siderophore-metal (III) complex of 4. The crystal of compound 5 was obtained by repeated recrystallization from n-hexane-chloroform (1:1) and subjected to single-crystal X-ray diffraction analysis with Cu Kα (Figure 4) (Flack parameter = 0.02 (6)), further confirming its planar structure and absolute configuration as cyclo-(L-Ala-NH)Orn-L-AcN(OH)Orn-L-Leu-D-Phe) chelating with Al (III).

Fe (III)-acremonpeptide F (6) was obtained as an orange-red solid. NMR spectra indicated the possible presence of Fe (III) in compound 6 as compound 3. The HRESIMS data of compound 6 displayed an [M + H]^+ ion at m/z 917.3520, corresponding to a molecular formula of C_{39}H_{56}N_{12}Fe, which indicated that compound 6 may be the complex of 4 by chelating Fe (III). Its planar structure was further verified by the ESIMS/MS fragments of m/z 745.2768 [M-AcN(OH)Orn + H]^+, m/z 658.2411 [M-AcN(OH)Orn-Ser + H]^+, m/z 545.1639 [M-AcN(OH)Orn-Ser-Leu + H]^+, and m/z 398.0899 [M-AcN(OH)Orn-Ser-Leu-Phe + H]^+ (Figure 3). The absolute configuration of the amino acid residues of 6 was established by advanced Marfey’s method and a shared biogenesis, confirming L-Ser, L-Leu, D-Phe, and three L-AcN(OH)Orn residues in 6.

Ga (III)-acremonpeptide E (7) and Ga (III)-acremonpeptide F (8) were obtained as white powders prepared from acremonpeptide E (2) and F (4) with Ga_2(SO_4)_3·H_2O, respectively. The structures of compounds 7 and 8 were further identified under the guidance of HRESIMS and NMR data (Figures S54–S60 for 7 and Figures S63–S69 for 8).

Aaselacin D (9) was isolated as a faint yellow solid, and its molecular formula was assigned as C_{46}H_{66}N_{10}O_{10} on the basis of HRESIMS. The 13C NMR and distortionless enhancement by polarization transfer (DEPT) spectra revealed 46 resonances, including 3 methyl, 17 methylene, 14 methane, 3 quaternary, and 9 carbonyl carbons. The presence of signals in the amide NH and α-amino acid protons in 1H NMR spectrum and carbonyl groups of its 13C NMR data (Table 3) indicated the peptidic nature of this molecule. Interpretation of the TOCSY and HMBC correlations suggested the existence of Gly, Ala, Trp, Thr, and Gln residues, five common amino acid residues. In addition, two methylene groups (δH 2.54, δH 2.28, and δC 34.2/δH 3.47, δH 3.01, and δC 36.5) coupled to the carbonyl carbon δC 171.7 revealed the presence of a β-Ala residue. Whereafter, detailed 1D and 2D NMR data revealed that the remaining proton and carbon signals accounted
for an aliphatic chain containing a diene and two carbonyl groups (Table 3). The HMBC correlations of Gly-NH (δH 7.81)/Ala-CO (δC 172.8), Ala-NH (δH 8.97)/Trp-CO (δC 173.6), Trp-NH (δH 7.91)/β-Ala -CO (δC 171.7), β-Ala-NH (δH 7.34)/Thr-CO (δC 173.0), and Gln-NH (δH 8.45)/fatty acid-CO (δC 173.8) confirmed the sequence of Gly-Ala-Trp-βAla-Thr-Gln in this compound and the connection of aliphatic chain with amino group via the Gln residue. Furthermore, a cyclic depsipeptide, formed between Thr and Gly residues, was supported by the key correlations of Thr-3 (δH 5.40)/Gly (δC 168.2) and Thr-4 (δH 1.05)/Gly (δC 168.2). The absolute configuration of each amino acid residues was confirmed using advanced Marfey’s method. LC–MS analysis of the hydrolysate’s derivatives of each amino acid residue and comparison with the retention times of the standards assigned the L-Ala, L-Thr, D-Trp, and D-Gln (detected as D-Glu) in 9 (Figure S79). Finally, the configuration of E,E-diene in aliphatic chain was established from their proton-proton coupling constants of 15.6 Hz.

Aselacin C (10) was obtained as a faint yellow solid, and its molecular formula C_{46}H_{66}N_{8}O_{11} was suggested by the HRESIMS data at m/z 907.4929 [M + H]^+. 1H and 13C NMR data indicated that compound 10 shared high similar structural features with compound 9, except for an oxygen methylene group (δC 60.4) instead of the methyl (δC 16.2) at Ala, suggesting that the Ala in 9 was displaced by Ser residue in 10. A literature survey indicated 10 to be identical to the known compound aselacin C [16]. The application of advanced Marfey’s analysis supported the absolute configuration as depicted.

Invasive aspergillosis usually leads to a severe life-threatening infection, especially for immunocompromised patients [17,18]. Recently, ASP2397 (also known as VL-2397 under clinical trial), a hydroxamate-containing siderophore isolated from fungus Acremonium persicinum, exhibited potent antifungal activities [6,19]. Hydroxamic acids usually possess a formula RC(O)N(OH)R’ and can be regarded as a type of N-hydroxy amides [20]. Here, elucidation of acremonpeptide E; acremonpeptide F; and their complexes with Al^{3+}, Fe^{3+}, and Ga^{3+} (1–8) further enrich the chemical structural diversity of the hydroxamate siderophore family.

2.2. Biological Evaluation of These Compounds

Hydroxamate-containing compounds 1–8 were evaluated for antifungal activities against *Aspergillus fumigatus* and *Aspergillus niger*. We found that compounds 1, 5, 7, and 8 showed obvious antifungal activities against *A. fumigatus* and *A. niger* with MIC values ranging from 1 to 3 µM, which is comparable to the positive control amphotericin B (Table S1).

In line with the previous report, the free acremonpeptides or Fe (III)-acremonpeptides failed to show antifungal activities in biological evaluation [6]. We speculate that the tested fungi may use the free acremonpeptides or Fe (III)-acremonpeptides as a vector to take in Fe^{3+} for survival, but this could be blocked by acremonpeptides chelating other ions, which will occupy the transport receptor of absorption.

The cytotoxic assays indicated that compounds 1–10 were inactive against non-small cell lung cancer cell line A549, small cell lung cancer cell lines H446 and H1688, and human embryonic lung fibroblast cell MRC-5 at concentrations up to 30 µM. This result is consistent with the deductive mechanism of action for this class of compounds, targeting Sit1 of *Aspergillus* genus, which is lacking in mammalian cells, indicating the potential druggability of these compounds [21]. Aselacins D (9) and C (10) were not tested for the antifungal activity for the usage of samples.
Table 2. $^{13}$C NMR (150 MHz, DMSO-$d_6$) and $^1$H NMR (600 MHz, DMSO-$d_6$) data foracremonpeptide F (4), Al (III)-acremonpeptide F (5), and Ga (III)-acremonpeptide F (8).

3. Experimental Section

3.1. Fungal Material and Fermentation

The fungal strain Acremonium persicinum F10 was isolated from the fresh inner issue of marine sponge Phakellia fusca collected at a depth of 10–20 m near the Yongxin Island (112°20′ E, 16°50′ N) in the South China Sea in June 2013. This fungus was identified as Acremonium persicinum on the basis of morphological characteristics and sequence analysis. The spores of A. persicinum F10 were inoculated into 50 mL of seed medium (PDB) in a 250 mL Erlenmeyer flask and incubated on a rotary shaker at 25 °C (150 rpm) for 7 days. The subfractions Fr.A4 and Fr.A5 were combined and purified by semipreparative HPLC with methanol as eluent, giving fractions (Fr.A4B1-B3) and (Fr.A5B1-B3), respectively. The extract was subjected to MPLC with silica gel column eluted by gradients of ACN/Methanol (Jasco, Japan) with a 1.0 mL cell. IR spectra were recorded on a KBr pellets using a Fourier transform infrared spectrometer (FT-IR) (Nicolet 6700, Thermo Nicolet Co., Waltham, MA, USA). Optical rotations were recorded on a P-2000 digital polarimeter (PerkinElmer, Waltham, MA, USA). XRF spectra were obtained by X-ray fluorescence spectrometer (XRF-1800, Shimadzu, Japan). Mass spectra were measured on a positive ion mode using LC–HRMS (Waters Micromass Q-TOF Premier Mass Spectrometer, which was equipped with an electrospray interface). The NMR data were collected by a Bruker Avance III 600 MHz spectrometer (Bruker Co., Ltd., Karlsruhe, Germany) at 600 MHz for 1H and 13C nuclei. Chemical shifts are expressed in δ (ppm) and referenced to the solvent residual peak.

Al (III)-acrecmonopeptide E (1): white needle crystals; [α]25D + 31.7 (c 0.3, MeOH); UV (MeOH) λmax (log ε): 208 (4.48) nm; IR (KBr) νmax 3425, 2965, 1648, 1401 cm⁻¹; 1H and 13C NMR data, Table 1; HRESIMS m/z 872.4123 [M + H]+ (Calcd. for C39H59N9O12Al, m/z 872.4099 [M + H]+).
Acremonpeptide E (2): light yellow solid; [α]_D^{25} = 14.4 (c 1.0, MeOH); UV (MeOH) λ_{max} (log ε): 212 (4.20) nm; IR (KBr) ν_{max} 3424, 2931, 1643, 1527, 1415, 1007, 832 cm⁻¹; 1H and 13C NMR data, Table 1; HRESIMS m/z 848.4519 [M + H]^+ (Calcd. for C_{39}H_{62}N_{6}O_{12}, m/z 848.4518 [M + H]^+).

Fe (III)-acremonpeptide E (3): orange needle crystals; [α]_D^{25} = +161.0 (c 0.3, MeOH); UV (MeOH) λ_{max} (log ε): 208 (4.12), 428 (2.97) nm; IR (KBr) ν_{max} 3443, 2960, 2934, 1646, 1578, 1518, 1452 cm⁻¹; 1H and 13C NMR data, Table 1; HRESIMS m/z 901.3745 [M + H]^+ (Calcd. for C_{39}H_{59}N_{9}O_{12}Fe, m/z 901.3633 [M + H]^+).

Acremonpeptide F (4): light yellow solid; [α]_D^{25} = -0.60 (c 0.5, MeOH); UV (MeOH) λ_{max} (log ε): 206 (4.11) nm; IR (KBr) ν_{max} 3425, 2960, 2928, 1646, 1519, 1401, 1007, 832 cm⁻¹; 1H and 13C NMR data, Table 2; HRESIMS m/z 864.4471 [M + H]^+ (Calcd. for C_{39}H_{62}N_{6}O_{13}, m/z 864.4677 [M + H]^+).

Al (III)-acremonpeptide F (5): white needle crystals; [α]_D^{25} = +66.6 (c 0.5, MeOH); UV (MeOH) λ_{max} (log ε): 206 (4.19) nm; IR (KBr) ν_{max} 3425, 2960, 2928, 1646, 1519, 1401, 1007, 832 cm⁻¹; 1H and 13C NMR data, Table 2; HRESIMS m/z 888.4073 [M + H]^+ (Calcd. for C_{39}H_{59}N_{9}O_{13}Al, m/z 888.4048 [M + H]^+).

Fe (III)-acremonpeptide F (6): orange solid; [α]_D^{25} = +166.4 (c 0.05, MeOH); UV (MeOH) λ_{max} (log ε): 212 (4.26), 368 (3.86) nm; IR (KBr) ν_{max} 3415, 2928, 1630, 1551, 1401, 1007, 832 cm⁻¹; 1H and 13C NMR data, Table 2; HRESIMS m/z 917.3520 [M + H]^+ (Calcd. for C_{39}H_{59}N_{9}O_{13}Fe, m/z 917.3582 [M + H]^+).

Ga (III)-acremonpeptide F (7): white solid; [α]_D^{25} = +105.8 (c 0.5, MeOH); UV (MeOH) λ_{max} (log ε): 210 (4.15) nm; IR (KBr) ν_{max} 3425, 2961, 1647, 1517, 1401, 1006, 832 cm⁻¹; 1H and 13C NMR data, Table 1; HRESIMS m/z 914.3547 [M + H]^+ (Calcd. for C_{39}H_{59}N_{9}O_{12}Ga, m/z 914.3539 [M + H]^+).

Ga (III)-acremonpeptide F (8): colorless oil; [α]_D^{25} = +123.0 (c 0.5, MeOH); UV (MeOH) λ_{max} (log ε): 206 (4.20) nm; IR (KBr) ν_{max} 3425, 2962, 1646, 1520, 1401, 1007, 832 cm⁻¹; 1H and 13C NMR data, Table 2; HRESIMS m/z 930.3498 [M + H]^+ (Calcd. for C_{39}H_{59}N_{9}O_{13}Ga, 930.3488).

Atelacin D (9): light yellow solid; [α]_D^{25} = -3.0 (c 0.05, MeOH); UV (MeOH) λ_{max} (log ε): 206 (4.25), 274 (4.01) nm; IR (KBr) ν_{max} 3425, 2929, 1633, 1553, 1401, 1007, 832 cm⁻¹; 1H and 13C NMR data, Table 3; HRESIMS m/z 891.4996 [M + H]^+ (Calcd. for C_{46}H_{62}N_{6}O_{10}, m/z 891.4980 [M + H]^+).

### 3.4. In Vitro Chelate Compounds Synthesis

Here, in vitro chelation reactions of ligand compounds 2 and 4 with ferric, gallium, and aluminum ions were carried out. Firstly, 0.5 mL of each aqueous solution (0.01 mmol) of FeCl₃·6H₂O, Ga₂(SO₄)₃·H₂O, and Al₂(SO₄)₃·6H₂O was stirred at 120 rpm. Then, equivalent volume of compounds 2 or 4 were dissolved in methanol and added in previous aqueous solution to continue stirring for 3 h. Finally, the reaction mixtures were analyzed by UPLC-MS.

### 3.5. X-ray Crystallographic Analysis

Colorless crystals of 1, 3, and 5 were obtained by diffusing n-hexane into a chloroform solution. Single-crystal X-ray diffraction data were collected on a Bruker D8 VENTURE diffractometer using graphite-monochromated Cu Ka radiation (λ = 1.54178 Å). The parameters in Common Intermediate Format (CIF) format for 1, 3, and 5 are available from the Cambridge Crystallographic Data Center (CCDC) under the deposition number CCDC 1906911 for 1, 1906910 for 3, and 1906912 for 5, respectively (accessed on April 1, 2019). Copies of the data can be obtained free of charge via the Internet at www.ccdc.cam.ac.uk, accessed on 14 May 2021.

Crystal data for compound 1: The molecular structure comprises one molecule of 1 and two molecules of water. C_{39}H_{58}AlN_{9}O_{12}, 2 (H₂O), M = 903.92, white (block), monoclinic, space group P2₁(1), a = 12.2490 (3) Å, b = 11.9399 (3) Å, c = 16.7735 (5) Å, crystal size: 0.60 × 0.50 × 0.40 mm. V = 2410.97 (11) Å³, Z = 2, μ (Cu Ka) = 0.960 mm⁻¹, and F(000) = 320.0,
36,004 reflections measured, of which 8023 unique (\(R_{\text{int}}\) (R factor for symmetry-equivalent intensities) = 0.0399) were used in all calculations. The final R indices (all data) gave \(R_1 = 0.0419\), \(wR_2 = 0.1176\), and the Flack parameter = \(-0.10\) (5).

Crystal data for compound 3: The molecular structure comprises one molecule of 3 and two molecules of water. \(C_{39}H_{58}FeN_{9}O_{12}, 2\) (\(H_2O\), \(M = 932.79\), orange (block), monoclinic, space group \(P2(1)\), \(a = 12.1986\) (5) \(\AA\), \(b = 11.9950\) (5) \(\AA\), \(c = 16.7889\) (7) \(\AA\), crystal size: \(0.50 \times 0.40 \times 0.30\) mm. \(V = 2419.29\) (17) \(\AA^3\), \(Z = 2\), \(\mu (Cu Ka) = 3.088\) \(\text{mm}^{-1}\), and \(F(000) = 986.0\), 28,046 reflections measured, of which 7271 unique (\(R_{\text{int}}\) (R factor for symmetry-equivalent intensities) = 0.0290) were used in all calculations. The final R indices (all data) gave \(R_1 = 0.0802\), \(wR_2 = 0.2329\), and the Flack parameter = 0.04(8).

Crystal data for compound 5: The molecular structure comprises one molecule of 5. \(C_{59}H_{88}AlN_{6}O_{13}, M = 888.40\), colorless (block), monoclinic, space group \(P2(1)\), \(a = 12.207\) (3) \(\AA\), \(b = 12.049\) (4) \(\AA\), \(c = 16.512\) (7) \(\AA\), crystal size: \(0.22 \times 0.20 \times 0.18\) mm. \(V = 2392.3(14)\) \(\AA^3\), \(Z = 2\), \(\mu (Cu Ka) = 0.942\) \(\text{mm}^{-1}\), and \(F(000) = 944.0\), 17,328 reflections measured, of which 5253 unique (\(R_{\text{int}}\) (R factor for symmetry-equivalent intensities) = 0.0290) were used in all calculations. The final R indices (all data) gave \(R_1 = 0.1164\), \(wR_2 = 0.2371\), and the Flack parameter = 0.02 (6).

3.6. Acid Hydrolysis of Compounds 1–6, and 9

Approximately 0.6 mg of each of compounds 1–6 was hydrolyzed with 6 N HCl (1 mL) for 16 h at 110 °C. For analysis of compound 9, 3.0% \(\nu/\nu\) triisopropylsilane was added, and the mixture was hydrolyzed with 6 N HCl (1 mL) for 2 h at 110 °C. After cooling to room temperature, the hydrolysate mixtures and traces of HCl were evaporated to dryness.

3.7. Absolute Configurations of Amino Acids by the Advanced Marfey’s Analysis

Each acid hydrolysate was resuspended in 100 \(\mu\)L of \(H_2O\). To each half portion (50 \(\mu\)L), we added 1 N NaHCO\(_3\) (20 \(\mu\)L) and 100 \(\mu\)L of \(L\)-FDLA derivatives of amino acid standard and corresponding amino acids from each compound, we established the absolute configuration (Figures S11, S22, S39, and S79).

3.8. Antifungal Activity Assay

Compounds 1–8 were tested for antifungal activities against Aspergillus fumigatus ATCC204305 and Aspergillus niger ATCC16404 using broth microdilution antifungal susceptibility testing, according to previously published protocol [23,24]. In the experiments, the RPMI-1640 medium containing 10.4 g/L of RPMI-1640 medium (R8755; Sigma, St. Louis, MO, USA), 6.7 g/L of Yeast Nitrogen Base (YNB; Becton, Dickinson and Company, Franklin Lakes, NJ, USA), 1.8% (\(\nu/\nu\)) glucose, and 40 mM HEPES (pH = 7.1) was used as culture medium. The inoculum per well for a 96-well microplate was \(2 \times 10^4\) fresh conidia/mL (150 \(\mu\)L/well), which were incubated for 24 h at 37 °C. The minimal inhibitory concentration (MIC) in the assay were performed using resazurin at 0.002% (\(\nu/\nu\)) of final concentration. Amphotericin B was used as the positive control, exhibiting MICs at 1 \(\mu\)g/mL to both tested fungal strains.

3.9. Cytotoxicity Assay

The cytotoxic activity of compounds 1–10 against A549, H466, H1688, and MRC-5 cells (all cell lines were obtained from the Cell Bank of the Chinese Academy of Sciences, Shanghai, China) were evaluated by the MTT assay as described previously [25]. Cisplatin was used as the positive control with IC\(_{50}\) values of 3.8 \(\mu\)M, 1.9 \(\mu\)M, 3.0 \(\mu\)M, and 23.8 \(\mu\)M, respectively.
4. Conclusions

The organic extract of the sponge-derived fungus *Acremonium persicinum* F10 yielded two types of cyclopeptides, including six new hydroxamate siderophore cyclohexapeptides, acremonpeptides E, acremonpeptides F, and their chelates (1–6); a new cyclic pentapeptolide, aselacin D (9); and a known compound, aselacin C (10). Analyses of the spectroscopic data of NMR and HRESIMS elucidated the planar structures of these compounds, while the absolute configurations were confirmed using the advanced Marfey’s method and X-ray single-crystal diffraction analysis.

The differences among the new isolated acremonpeptide analogues 2 and 4 and the previously reported findings were varying amino acid replacements or simply different stereocenters (Figure S1), indicating the substrate tolerance of the biosynthesis pathway of the hydroxamate-based peptidyl siderophore from *Acremonium persicinum*.

The compounds 1, 5, 7, and 8 displayed high anti-fungal activities in vitro against *Aspergillus fumigatus* and *Aspergillus niger*, with MICs at 1 µg/mL. Meanwhile, all these compounds showed no cytotoxicity to normal cell (human embryonic lung fibroblast, MRC-5) at the concentration of 30 µM.
