Abstract
The convex hull peeling of a point set is obtained by taking the convex hull of the set and repeating iteratively the operation on the interior points until no point remains. The boundary of each hull is called a layer. We study the number of $k$-dimensional faces and the outer defect intrinsic volumes of the first layers of the convex hull peeling of a homogeneous Poisson point process in the unit ball whose intensity goes to infinity. More precisely we provide asymptotic limits for their expectation and variance as well as a central limit theorem. In particular, the growth rates do not depend on the layer.

1 Introduction
1.1 Context

Random polytopes as convex hulls of random points have been extensively studied in stochastic geometry. An overview of the subject can be found in [32] and [37, Chapter 8.2] for instance. Let $\mathcal{P}_\lambda$ be a Poisson point process with intensity measure $\lambda \, dx$ in a convex body $K$ of $\mathbb{R}^d$. The study of the asymptotic behaviour as $\lambda \to \infty$ of $\text{conv}(\mathcal{P}_\lambda)$ started with the work of Rényi and Sulanke in [33, 34], in a binomial setting. They
obtain in particular a different growth rate for the mean number of extreme points when $K$ is a smooth convex body with a $C^2$-regular boundary and when $K$ is a polytope, namely polynomial for the former and logarithmic for the latter. Since then diverse results on the number of $k$-dimensional faces and on the defect intrinsic volumes of $\text{conv}(P_\lambda)$ have been proved for both choices of $K$. We only consider the smooth case in this paper. Asymptotic expectations are shown notably in [2, 31, 36]. In particular, it is known that the mean number of extreme points grows like $\lambda^{\frac{d-1}{d+1}}$ up to a multiplicative constant. First-order results have then been complemented by central limit theorems in [13, 30, 39]. Results on the variance of these quantities go from general bounds in [3, 5] to explicit limits in [13, 14]. In parallel, concentration inequalities have been derived in [23, 40]. The explicit formulas obtained by [11, 25, 26] are worth noting among the very few non-asymptotic results available.

The subject of this paper is a generalization of the study of the convex hull of random points to the so-called convex hull peeling. We start by taking the convex hull of the whole process and then repeatedly take the convex hull of the points that were not extreme at the previous step until no point remains. Let us write $\text{conv}_1(P_\lambda) := \text{conv}(P_\lambda)$ and by induction for any $n \geq 1$, $\text{conv}_{n+1}(P_\lambda) := \text{conv}(\text{int}(\text{conv}_n(P_\lambda))) \cap P_\lambda$). The boundary of the $n$-th convex hull $\partial \text{conv}_n(P_\lambda)$ will be called the $n$-th layer of the convex hull peeling of $P_\lambda$. The words peeling and layers were chosen by analogy with the peeling of an onion, see Fig. 1.

The convex hull peeling was first introduced by Barnett in [7] as a way to order multivariate data and give a meaning to how central a point is with respect to a dataset. Indeed, the layer number of a point can be interpreted as the depth of that point with respect to the input and we expect it to be all the larger the more central the point is. The convex hull peeling has then been used in robust statistics and outlier detection, see [22, 24, 35]. It fits into a list of classical techniques for ordering multivariate data, including half-space depth, simplicial depth or zonoid depth, see e.g. [18] for an overview on these techniques.
However it seems that very few theoretical results exist on the convex hull peeling of a random sample. For instance, the survey [32] devotes a small section on convex hull peeling but does not provide any reference and states that in continuation with the available asymptotic results for the convex hull, investigations concerning expectations and deviation inequalities [for the subsequent layers of the convex hull peeling] are unknown. To the best of our knowledge, there are mostly two papers which deal with the asymptotic properties of the convex hull peeling of random points. The first one due to Dalal [20] states that the mean total number of layers of the convex hull peeling of \( n \) i.i.d. uniform points in any bounded region of \( \mathbb{R}^d \) is lower and upper bounded by multiples of \( n^{2/d} \). Very recently, a breakthrough work by Calder and Smart [12] greatly improves Dalal’s estimate. Let \( \mathcal{P}_{\lambda, f} \) be a Poisson point process of intensity measure \( \lambda f(x) dx \) in \( K \) with \( f \) a continuous and positive function on \( K \). They consider the convex height function \( h_\lambda(x) \) of any point \( x \) in \( \mathbb{R}^d \) as the largest \( n \) such that \( x \in \text{int}(\text{conv}_n(\mathcal{P}_{\lambda, f})) \). Note that Dalal’s work covers the particular problem of estimating the expectation of \( \max h_\lambda \) when \( f = 1 \). Calder and Smart show that \( \lambda^{-2/d} h_\lambda \) converges uniformly in probability with an explicit exponential bound and almost surely to a multiple of a function \( h \) which is the unique viscosity solution of an explicit PDE. In other words, they obtain in particular that when \( \lambda \to \infty \), almost surely

\[
\lambda^{-2/d} h_\lambda \xrightarrow{\text{unif}} \alpha h \tag{1.1}
\]

where \( \alpha \) is a positive constant which depends only on dimension \( d \) and \( h \) is the unique viscosity solution of

\[
\begin{cases}
\langle Dh, \text{cof}(-D^2 h) Dh \rangle = f^2 \text{ in int}(K) \\
h = 0 \text{ on } \partial K
\end{cases}
\]

\( \text{cof}(\cdot) \) being the cofactor matrix. Denoting by \( \mathbb{B}^d \) the unit ball of \( \mathbb{R}^d \), we observe that (1.1) implies in the particular case when \( K = \mathbb{B}^d \) and \( f = 1 \) that the rescaled total number of layers of the peeling satisfies almost surely

\[
\lambda^{-2/d} \max h_\lambda \xrightarrow{\text{as}} \beta_d := \frac{(d + 1)\alpha}{2d^{d-1} \text{Vol}_{d-1}(S^{d-1})} \tag{1.2}
\]

where \( \text{Vol}_{d-1}(S^{d-1}) \) is the surface area of the \((d - 1)\)-dimensional unit sphere \( S^{d-1} \).

Because of the normalization of \( h_\lambda \) in (1.1), this uniform convergence result can only provide information on the regime of the peeling limited to layers numbered \( \lambda^{2/d} \) up to a multiplicative constant. The authors do not investigate any combinatorial or geometric functional of these layers. Nonetheless, they conjecture with a short heuristic argument that the number \( N_{n(\lambda, t), 0, \lambda} \) of Poisson points on a layer numbered \( n(\lambda, t) := \lfloor t \lambda^{2/d} \rfloor \) should satisfy a law of large numbers when \( \lambda \to \infty \), i.e. almost
surely

$$\lambda^{\frac{d-1}{d+1}} N_{n(\lambda, t), 0, \lambda} \longrightarrow \int_{\{\alpha h = t\}} f^{\frac{d-1}{d+1}} \kappa^{\frac{1}{d+1}} dS$$

where $\kappa$ is the Gauss curvature of the level set $\{\alpha h = t\}$ and $dS$ is the Hausdorff measure of that set. In particular, when $K$ is the unit ball and $f = 1$, the conjectured result should read, see [12, displays (1.16)–(1.19)],

$$\lambda^{\frac{d-1}{d+1}} N_{n(\lambda, t), 0, \lambda} \longrightarrow \frac{d + 1}{2\beta_d} \left(1 - \beta_d^{-1} t\right)^{\frac{d+1}{d}}$$

(1.3)

where the constant $\beta_d$ is introduced at (1.2).

In comparison to [12], our approach is different, i.e. we consider the case $K = \mathbb{B}^d$ and $f = 1$, we choose to fix a layer numbered $n$ that does not depend on $\lambda$ and study the geometric properties of $\partial \text{conv}_n(P_\lambda)$ as $\lambda \to \infty$. In other words, we investigate a different regime, namely the regime of the first layers in the context of uniform points in the ball. There are several reasons to do so: when applying the convex hull peeling to outlier detection, we expect the outliers to be located on the first layers of the peeling, which provides some motivation for understanding the cardinality of these particular layers. Moreover, we intend to use a global scaling transformation on the ball which has been introduced in [13] for the study of the convex hull and which is expected to bring exhaustive information on the visible layers after rescaling, namely the first layers.

1.2 Model

Let $P_\lambda$ be a Poisson point process of intensity measure $\lambda dx$ in the unit ball $\mathbb{B}^d$ of $\mathbb{R}^d$. We construct the consecutive hulls $\text{conv}_n(P_\lambda)$, $n \geq 1$, of the peeling of $P_\lambda$. For $n \geq 1$ and $k \in \{0, \ldots, d - 1\}$, we denote by $N_{n,k,\lambda}$ the number of $k$-dimensional faces of the $n$-th layer $\partial \text{conv}_n(P_\lambda)$ and for $k \in \{1, \ldots, d\}$, by $V_{n,k,\lambda}$ the defect $k$-dimensional intrinsic volume of $\text{conv}_n(P_\lambda)$, i.e.

$$V_{n,k,\lambda} = V_k(\mathbb{B}^d) - V_k(\text{conv}_n(P_\lambda))$$

(1.4)

where $V_k$ stands for the $k$-th intrinsic volume, see for example [37, p. 600] for a definition and some properties of the intrinsic volumes.

We focus on these two families of random variables and aim at studying their first and second-order properties.

1.3 Main results

For two non-negative functions $f$ and $g$, we write $f = O(g)$ if there exist a constant $C > 0$ and $\lambda_0 > 0$ such that for any $\lambda \geq \lambda_0$ we have $f(\lambda) \leq C g(\lambda)$. Theorem 1.1
below provides expectation and variance asymptotics as well as a central limit theorem for the variables $N_{n,k,\lambda}$.

**Theorem 1.1** For any $n \geq 1$ and $k \in \{0, \ldots, d-1\}$ there exist $C_{n,k,d}, C'_{n,k,d} \in (0, \infty)$ such that

$$\lim_{\lambda \to +\infty} \lambda^{-\frac{d-1}{d+1}} \mathbb{E}[N_{n,k,\lambda}] = C_{n,k,d}$$

and

$$\lim_{\lambda \to +\infty} \lambda^{-\frac{d-1}{d+1}} \text{Var}[N_{n,k,\lambda}] = C'_{n,k,d}.$$

Moreover, when $\lambda \to \infty$, we have

$$\sup_t \left| \mathbb{P} \left( \frac{N_{n,k,\lambda} - \mathbb{E}[N_{n,k,\lambda}]}{\sqrt{\text{Var}[N_{n,k,\lambda}]}} \leq t \right) - \mathbb{P}(\mathcal{N}(0, 1) \leq t) \right| = O \left( \lambda^{-\frac{d-1}{2(d+1)}} (\log \lambda)^{3d+1} \right).$$

In Theorem 1.2, we derive similar results for the variables $V_{n,k,\lambda}$.

**Theorem 1.2** For any $n \geq 1$ and $k \in \{1, \ldots, d\}$ there exist $C_{V,n,k,d}, C'_{V,n,k,d} \in (0, \infty)$ such that

$$\lim_{\lambda \to +\infty} \lambda^{\frac{2}{d+1}} \mathbb{E}[V_{n,k,\lambda}] = C_{V,n,k,d}$$

and

$$\lim_{\lambda \to +\infty} \lambda^{\frac{d+3}{2(d+1)}} \text{Var}[V_{n,k,\lambda}] = C'_{V,n,k,d}.$$

Moreover, when $\lambda \to \infty$, we have

$$\sup_t \left| \mathbb{P} \left( \frac{V_{n,k,\lambda} - \mathbb{E}[V_{n,k,\lambda}]}{\sqrt{\text{Var}[V_{n,k,\lambda}]}} \leq t \right) - \mathbb{P}(\mathcal{N}(0, 1) \leq t) \right| = O \left( \lambda^{-\frac{d-1}{2(d+1)}} (\log \lambda)^{3d+1} \right).$$

The growth rates of the expectations and variances in Theorems 1.1 and 1.2 are identical to those obtained for the first layer, i.e. the convex hull of $\mathcal{P}_\lambda$, as described in [13]. In particular, the underlying limiting expectations and variances are proved to be different from zero. They have an explicit formulation in terms of a random process derived from a homogeneous Poisson point process in the product space $\mathbb{R}^{d-1} \times \mathbb{R}_+$, see Theorems 2.10–2.13. This solves the conjecture discussed in [12] and along the lines above (1.3) in the particular regime when the layer number does not depend on the size of the input.

Complementary Gaussian limit distributions in Theorems 1.1 and 1.2 are comparable to those in [13] with similar convergence rates. In particular, these rates have been recently improved without the log factor in [28] for the first layer. Nevertheless, the extension of their techniques to subsequent layers is not direct in our opinion, see the remark about optimal Berry-Esseen bounds in Sect. 6.

Our tools are those of stabilization theory that were used in [13] to prove precise variance asymptotics for the first layer. The key idea consists in writing $N_{n,k,\lambda}$ and $V_{n,k,\lambda}$ as a sum $\sum_{x \in \mathcal{P}_\lambda} \xi(x, \mathcal{P}_\lambda)$ for some functional $\xi$ and proving that for a given point $x$ this functional only depends on the process in a neighbourhood of $x$. That is what we call stabilization. The importance of the stabilization can already be seen in the
study of the variance of $N_{n,k,\lambda}$ as it implies that $\xi(x, P_{\lambda})$ and $\xi(y, P_{\lambda})$ are independent when $x$ and $y$ are far enough from each other, which simplifies the calculation of the variance. The stabilization of $\xi$ is in fact used much more extensively for all six results stated in Theorems 1.1 and 1.2 and constitutes the main difficulty of this paper. Indeed, the formation of each layer of the peeling requires a global knowledge of the point set and also of the history of the previously constructed layers. In particular, for a given point $x$, there is no easy local criterion for checking that $x$ is on the $n$-th layer of the peeling. In this regard, the problem is significantly different from the study of the convex hull as done in [13]. The only characterization that we can use is incremental, see Lemma 2.5, and this explains why the proof of stabilization is done by induction on the layer number. Incidentally, this also requires to estimate the position of each layer, see e.g. Lemma 3.2.

The strategy of proof of the expectation and variance asymptotics in Theorem 1.1 is the following.

– Using the decomposition of each variable as a sum over $x \in P_{\lambda}$ of a functional $\xi(x, P_{\lambda})$, we rewrite the expectation and variance of $N_{n,k,\lambda}$ as an integral thanks to Mecke’s formula for Poisson point processes.

– Dealing with this multiple integral, we intend to use Lebesgue’s dominated convergence theorem after applying a suitable change of variables inside the integral. To do so, we need to rescale the model. This leads us to introducing the notions of parabolic hull peeling in the upper half-space, see Sect. 2.

– It then remains to show the convergence and domination of the integrands, rewritten as either an expectation or a covariance of a local functional of the parabolic hull peeling. This requires to show the so-called stabilization of the functionals, see Sect. 3. The stabilization implies in turn general moment bounds and the convergence of the integrands, see Sect. 4.

The proof of the central limit theorem also relies on the stabilization results from Sect. 3 as well as a Gauss approximation result in the particular setting of dependency graphs.

Finally, showing the positivity of the limiting expectations and variances represents another challenge. It requires to introduce a particular configuration where the determination of the layers and the calculation of the considered variables are natural and then to randomize this idealized configuration. This general principle has been used previously for proving the positivity of the limiting variances of $N_{0,k,\lambda}$ and $V_{0,k,\lambda}$, see e.g. [30] and [3]. The construction that we do in the context of the $n$-th layer is partly inspired by [20].

We have chosen to concentrate mainly on the variables $N_{n,k,\lambda}$ throughout the paper and to discuss briefly the adaptations that are needed in the case of the variables $V_{n,k,\lambda}$ at the end of the paper, see Sect. 5.2.

1.4 Outline

The paper is structured as follows.

– In Sect. 2 we introduce the scaling transformation and study its effect on the point process and on the subsequent convex hulls. Incidentally we state a few basic
properties on the peeling. We then define the scores as functionals of a point $x$ and of the point process such that
the variables $N_{n,k,\lambda}$ and $V_{n,k,\lambda}$ can be decomposed as sums of such scores.
We conclude with statements of more refined versions of the expectation and variance asymptotics of Theorem 1.1, with precise limiting constants.

- Section 3 is devoted to proving the stabilization of the rescaled scores, i.e. that
with probability exponentially close to 1 they only depend on the process in the neighbourhood of the point considered.

- In Sect. 4 we use stabilization properties shown to prove $L^p$ bounds and a convergence of in expectation of the rescaled scores.

- Section 5 contains the proofs of our main results.

- Finally, Sect. 6 collects several concluding remarks about possible extensions of our work and open problems.

2 Rescaling and scores

In this section, we introduce an ad hoc scaling procedure originated in [38] and [13].
We then study the image by that scaling transformation of the Poisson point process and of the layers of the underlying convex hull peeling. Next we prove general properties on the construction of the rescaled layers which are analogues of similar properties of the initial convex hull peeling. Finally we introduce functionals that we call scores and we decompose $N_{n,k,\lambda}$ as the sum over every point of the process of these scores. This leads us to write explicit formulas for the constants in Theorem 1.1 and 1.2, where scores are involved.

2.1 Scaling transformation

To describe the scaling transformation that we will use on the point process, we first recall a few definitions. We write $T_{e_d}$ for the tangent space of $S^{d-1}$ at point $e_d = (0, 0, \ldots, 0, 1)$. The exponential map $\exp_{e_d} : T_{e_d} \cong \mathbb{R}^{d-1} \rightarrow S^{d-1}$ maps a vector $v$ of $T_{e_d}$ to the vector $u$ that lies at the end of the geodesic of $S^{d-1}$ of length $\|v\|$ that starts at $e_d$ with direction $v$. The function $\exp_{e_d}$ induces a one-to-one map between $B^d = [0, -e_d]$ and $W_\lambda := \lambda \frac{1}{\pi^{d/2}} B_{d-1}(\pi) \times [0, \lambda \frac{2}{\pi^{d/2}}]$ by

$$T^{(\lambda)}(x) := \left( \frac{1}{\lambda \frac{1}{\pi^{d/2}}} \exp^{-1} \left( \frac{x}{\|x\|} \right), \lambda \frac{2}{\pi^{d/2}} (1 - \|x\|) \right)$$

for all $x \in B^d \setminus [0, -e_d]$. In general we will denote by $w = (v, h)$ with $v \in \mathbb{R}^{d-1}$ and $h \in \mathbb{R}_+$ a generic point in $W_\lambda$. The transformation $T^{(\lambda)}$ was already used in [13] to obtain variance asymptotics of functionals of the convex hull of $\mathcal{P}_\lambda$ that include the number of $k$-faces (short for $k$-dimensional faces) and the $k$-th intrinsic volume. This transformation enjoys two important properties. First, unit volume subsets of $W_\lambda$ near
the hyperplane $\mathbb{R}^{d-1} \times \{0\}$ contain $\Theta(1)$ rescaled points and actually, we can show that the limit point process is Poisson and has intensity 1, see Lemma 2.1. Secondly, the transformation preserves the parabolic shape of both the defect radius-vector function and the defect support function of the random polytope $\text{conv}(\mathcal{P}_\lambda)$, as described in [13, p. 53–54]. These properties have been crucial in the proofs of the results contained in [13] on the convex hull $\text{conv}(\mathcal{P}_\lambda)$. It turns out that $T^{(\lambda)}$ plays a similar role for the first $n$ layers as long as we take a fixed $n$ that does not vary with $\lambda$. Indeed, at the limit, the convex hull is mapped by $T^{(\lambda)}$ to what we call the parabolic hull of the limit rescaled process. In the same way it maps the convex hull peeling to the analogue of the peeling procedure in the parabolic picture that we name parabolic hull peeling of the limit rescaled process. We give more details below, after describing the effect of $T^{(\lambda)}$ on $\mathcal{P}_\lambda$.

Our scaling transformation maps the Poisson point process $\mathcal{P}_\lambda$ to a Poisson point process on $W_\lambda$ that we denote by $\mathcal{P}^{(\lambda)}$. Its intensity has a density with respect to the Lebesgue measure given by

$$
(v, h) \mapsto \sin^{d-2} \frac{\lambda - \frac{1}{\pi + 1} \|v\|}{\|\lambda - \frac{1}{\pi + 1} v\|^{d-2}} \left(1 - \lambda - \frac{2}{\pi + 1} h\right),
$$

(2.1)

see [13, p. 57] for the computation. As proved in [13, p. 71], this point process converges in distribution to a homogeneous Poisson point process of intensity one on $\mathbb{R}^{d-1} \times \mathbb{R}_+$, that we denote by $\mathcal{P}$ or $\mathcal{P}^{(\infty)}$.

**Lemma 2.1** We have $\lim_{\lambda \to +\infty} \mathcal{P}^{(\lambda)} = \mathcal{P}$ in distribution.

Next we recall from [13] the effect of the rescaling on the spherical caps in the ball. This will then allow us to deduce the images of the consecutive layers by the rescaling. Any spherical cap in the unit ball of $\mathbb{R}^d$ can be written

$$
cap(x_0) := \left\{ x \in \mathbb{B}^d : \frac{x_0}{\|x_0\|} > \|x\| \right\}, \quad x_0 \in \mathbb{B}^d.
$$

(2.2)

One can see that $\cap(x_0)$ is the cap orthogonal to $x_0$ at distance $\|x_0\|$ of the origin. Let us write $(v_0, h_0) := T^{(\lambda)}(x_0)$. The cap $\cap(x_0)$ is sent by $T^{(\lambda)}$ to a so-called downward quasi-paraboloid $[\Pi_{\downarrow}^{(\lambda)}(v_0, h_0)]$. Furthermore, the quasi-paraboloids $[\Pi_{\downarrow}^{(\lambda)}(v_0, h_0)]$ converge to a paraboloid

$$
[\Pi_{\downarrow}^{(v_0, h_0)}]^{(\infty)}(v_0, h_0)
$$

$$
= \Pi_{\downarrow}^{(v_0, h_0)} := \left\{(v, h) \in \mathbb{R}^{d-1} \times \mathbb{R}_+ : h < h_0 - \frac{\|v - v_0\|^2}{2} \right\}.
$$

These results are made precise in Lemma 2.2 below, whose proof can be found in [13, p. 72-73] or in [15, Lemma 3.1] up to a small adaptation. Note that in this convergence result, with a slight abuse, we use the notation $\partial[\Pi_{\downarrow}^{(\lambda)}]$ (resp. $\partial[\Pi_{\downarrow}]$) for the function from $\mathbb{R}^{d-1}$ to $\mathbb{R}_+$ whose graph is the boundary of the set $[\Pi_{\downarrow}^{(\lambda)}]$ (resp. $\Pi_{\downarrow}$).
Beforehand, we need to introduce useful notation for several types of cylinders that are used in the rest of the paper. For any \( v \in \mathbb{R}^{d-1} \) and \( r > 0 \), \( C_v(r) \) denotes the vertical cylinder \( B_{d-1}(v, r) \times [0, r] \), with the convention \( C_r = C_0(r) \). We also define the truncated cylinders \( C_v^\pm(t) := C_v(r) \cap \{(v', h') \in \mathbb{R}^d : h' \geq t \}, C_v^\pm(t) := C_v(r) \cap \{(v', h') \in \mathbb{R}^d : h' \leq t \} \) and \( C_v^\pm(t) := C_v(r) \cap \{(v', h') \in \mathbb{R}^d : h' \in I \} \) for any \( t > 0 \) and any interval \( I \subset \mathbb{R}_+ \).

**Lemma 2.2** Let \( \lambda > 0 \) and \( x_0 \in \mathbb{R}^d \). We write \( (v_0, h_0) = T^{(\lambda)}(x_0) \). Then we have

\[
T^{(\lambda)}(\text{cap}(x_0)) = \left[ \Pi \right]^{(\lambda)}(v_0, h_0)
\]

\[
= \left\{ (v, h) \in W_\lambda : h < \lambda^{\frac{2}{d+1}} (1 - \frac{1}{\cos(e_\lambda(v, v_0))}) \right\} \tag{2.3}
\]

where \( e_\lambda(v, v_0) := d_{\mathbb{R}^{d-1}}(\exp_{d-1}(\lambda^{\frac{2}{d+1}} v), \exp_{d-1}(\lambda^{\frac{2}{d+1}} v_0)) \) for \( v, v_0 \in \mathbb{R}^{d-1} \). Additionally, for any \( L \geq 1 \), we have the following convergence result.

\[
\lim_{\lambda \to \infty} \partial \left[ \Pi \right]^{(\lambda)}(v_0, h_0) \cap C(v_0, h_0)(L) = \partial \Pi^{\lambda}(v_0, h_0) \cap C(v_0, h_0)(L). \tag{2.4}
\]

**Remark 2.3** As in [13], when \( \lambda \in (0, \infty) \), we can introduce a dual set

\[
\left[ \Pi \right]^{(\lambda)}(v_0, h_0) := T^{(\lambda)} \left( \partial B \left( \frac{x_0}{2}, \frac{\|x_0\|}{2} \right) \right)
\]

\[
= \left\{ (v, h) \in W_\lambda : h > \lambda^{\frac{2}{d+1}} (1 - (1 - \lambda^{\frac{2}{d+1}} h_0) \cos(e_\lambda(v, v_0))) \right\} \tag{2.5}
\]

that we call the upward quasi-paraboloid with apex \( (v_0, h_0) \). Similarly, we define

\[
\left[ \Pi \right]^{(\lambda)}(v_0, h_0) = \Pi^{\lambda}(v_0, h_0) := \left\{ (v, h) \in \mathbb{R}^{d-1} \times \mathbb{R}_+ : h > h_0 + \frac{\|v - v_0\|^2}{2} \right\}. \tag{2.6}
\]

In particular, for any \( \lambda \in (0, \infty) \) and any \((v_0, h_0), (v_1, h_1) \in W_\lambda\),

\[
((v_1, h_1) \in \left[ \Pi \right]^{(\lambda)}(v_0, h_0)) \iff ((v_0, h_0) \in \left[ \Pi \right]^{(\lambda)}(v_1, h_1)).
\]

This fact will be used on many occasions in the forthcoming proofs.

Recalling that for a locally finite point set \( X \),

\[
\text{conv}(X) = \bigcup_{H^\pm \text{ half-space}} (H^+)^c,
\]

we are led by Lemma 2.2 to the following definition, that corresponds to the analogue of the convex hull in the (quasi-)parabolic setting, where the role of the half-spaces is
played by downward quasi-paraboloids or paraboloids. For \( \lambda \in (0, \infty] \) and a locally finite point set \( Y \) in \( W_\lambda \), we write
\[
\Phi^{(\lambda)}(Y) := \bigcup_{w \in W_\lambda} [\Pi_1^{\downarrow}]^{(\lambda)}(w)^c \quad \text{such that} \quad Y \cap [\Pi_1^{\downarrow}]^{(\lambda)}(w) = \emptyset
\]
that we call the quasi-parabolic hull of \( Y \), or parabolic hull when \( \lambda = \infty \). We will generally write \( \Phi^{(\infty)} \) instead of \( \Phi^{(\infty)}(\lambda) \) for sake of simplicity.

Thanks to Lemma 2.2, we obtain that \( T^{(\lambda)} \) maps the convex hull of a point set to the quasi-parabolic hull of the image of this point set, i.e.
\[
T^{(\lambda)}(\conv(X)) = \Phi^{(\lambda)}(T^{(\lambda)}(X)),
\]
provided that \( \conv(X) \) contains the origin in its interior. In particular, when \( X = P_\lambda \), Wendel’s formula [41] shows that the event \( \{0 \in \int(\conv(P_\lambda))\} \) has a probability going to 1 exponentially fast when \( \lambda \to \infty \) and we implicitly condition on that event when working with \( T^{(\lambda)} \).

We call extreme points of \( Y \) the points of \( Y \cap \partial \Phi^{(\lambda)}_1(\lambda) \). They are naturally images by \( T^{(\lambda)} \) of the extreme points of the convex hull of \( [T^{(\lambda)}]^{-1}(\lambda) \).

When \( \lambda \to \infty \), the intersection \( \partial \Phi^{(\lambda)}_1(P^{(\lambda)}) \cap C(R) \) converges in distribution to \( \partial \Phi(P) \cap C(R) \) where each quasi-parabolic hull is seen as a continuous function over \( C(R) \) and the set of continuous functions on \( C(R) \) is endowed with the topology of the uniform convergence, see [13, Theorem 4.1].

Let us now investigate the action of the transform \( T^{(\lambda)} \) on the convex hull peeling procedure. Quite naturally, it maps the convex hull peeling to a quasi-parabolic hull peeling that will converge in some sense to a parabolic hull peeling. We define the hulls of the quasi-parabolic and parabolic hull peeling recursively with the following formula: for all \( n \geq 2, \lambda \in (0, \infty] \) and a locally finite point set \( Y \subset \mathbb{R}^{d-1} \times \mathbb{R}_+ \), we set
\[
\Phi^{(\lambda)}_n(Y) = \Phi^{(\lambda)}(Y \cap \int(\Phi^{(\lambda)}_{n-1}(Y))).
\]
When \( \lambda = \infty \), we speak of parabolic hull peeling and we write \( \Phi_n \) instead of \( \Phi^{(\infty)}_n \). In the same way as for the the first layer of the convex hull peeling, the subsequent ones are mapped by \( T^{(\lambda)} \) to the corresponding parabolic hulls, i.e.
\[
T^{(\lambda)}(\conv_n(X)) = \Phi^{(\lambda)}_n(T^{(\lambda)}(X)), \tag{2.7}
\]
presented provided that the origin lies in the interior of \( \conv_n(X) \). It is a direct consequence of [12, Theorem 1.2], see also (1.1), and [12, Equation (1.10) for \( x = 0 \)] that the event \( \{0 \in \int(\conv_n(P_\lambda))\} \) has a probability going to 1 exponentially fast when \( \lambda \to \infty \). Henceforth, when dealing with \( \conv_n \), we implicitly condition on that particular event.

We call the sets \( \partial \Phi^{(\lambda)}_n(Y) \) the layers of the quasi-parabolic or parabolic hull peeling of \( Y \).
For any $n \geq 1$, the set $\Phi_n^{(\lambda)}(Y)$ (resp. $\Phi_n(Y)$) is the complement of a union of down quasi-paraboloids (resp. paraboloids). As the quasi-paraboloids converge to paraboloids, see Lemma 2.2, and $W_\lambda$ goes to $\mathbb{R}^{d-1} \times \mathbb{R}_+$ as $\lambda$ goes to infinity, we can extend [13, Theorem 4.1] to the convergence in distribution of the subsequent rescaled layers of the original convex peeling to the corresponding layers of the parabolic peeling associated with the limit Poisson point process. As a side result, we also obtain the convergence of the point process of points of $P^{(\lambda)}$ on the $n$-th layer. This is summarized in Proposition 2.4 below.

**Proposition 2.4** Let $R > 0$ and $n \geq 1$. When $\lambda \to \infty$, we have that

$$\partial \Phi_n^{(\lambda)}(P^{(\lambda)}) \xrightarrow{L} \partial \Phi_n(P)$$

where the set of continuous functions over $\mathbb{R}^{d-1}$ is endowed with the topology of the uniform convergence on every compact set. Moreover,

$$P^{(\lambda)} \cap \partial \Phi_n^{(\lambda)}(P^{(\lambda)}) \xrightarrow{L} P \cap \partial \Phi_n(P).$$

In other words, Proposition 2.4 explains to what extent the parabolic hull peeling is the rescaled limiting model of the convex hull peeling in the ball. Since Proposition 2.4 is a natural analogue of the results stated and proved in [13, Theorem 4.1] and [15, Theorem 1.1] for the (quasi)-parabolic hull process, its proof is omitted. Let us note that when $\lambda = \infty$, the parabolic hull peeling of $P$, as seen in Fig. 2, is also a crucial tool of [12] under the name of semiconvex peeling.

### 2.2 Properties of the rescaled layers

For any $w \in \mathbb{R}^{d-1} \times \mathbb{R}_+$ and $Y \subset \mathbb{R}^{d-1} \times \mathbb{R}_+$, we introduce the number

$$\ell^{(\lambda)}(w, Y) = n \text{ such that } w \in \partial \Phi_n^{(\lambda)}(Y \cup \{w\}).$$

Fig. 2 First layers of a parabolic hull peeling, with the interior of $\Phi_5(P)$ in pink (color figure online)
In particular, for any \( x \in \mathbb{R}^d \), \( \ell(\lambda)(w, Y, X) \) is the number of the layer of \( x \) in the initial convex hull peeling of \( X \cup \{ w \} \). We now aim at proving an explicit criterion for determining \( \ell(\lambda)(w, Y, X) \), see Lemma 2.5, and the monotonicity of \( \ell(\lambda)(w, Y, X) \) with respect to \( Y \), see Lemma 2.6. Both of these properties can be stated for the initial convex hull peeling as well. The non-rescaled versions are not needed for our purpose but for sake of completeness, we provide these statements at the end of this section.

Let us recall, see e.g. [13, pages 66-67], that a point \( w \) in \( \mathbb{R}^d - \mathbb{R}^+ \) is extreme if and only if there exists \( (v_1, h_1) \in \partial \Pi^{\lambda}_{\uparrow}(w) \) such that \( \Pi^{\lambda}_{\downarrow}(v_1, h_1) \cap Y = \emptyset \).

Lemma 2.5 provides a geometric interpretation of the function \( \ell(\lambda) \) that extends the result above and that we will use frequently—and sometimes implicitly—in the rest of the paper, see Fig. 3 for an illustration of this lemma.

**Lemma 2.5** Let \( Y \) be a locally finite subset of \( \mathbb{R}^{d-1} \times \mathbb{R}_+ \), \( w \in Y \), \( \lambda \in (0, \infty) \) and \( n \geq 2 \). Then we have the two following equivalences.

\[
\begin{align*}
(i) \quad & (\ell(\lambda)(w, Y) \geq n) \iff (\forall (v_1, h_1) \in \partial [\Pi_{\uparrow}^{\lambda}](w) : Y \cap [\Pi_{\downarrow}^{\lambda}](v_1, h_1) \nsubseteq \bigcup_{i=1}^{n-1} \partial [\Phi_i^{\lambda}](Y)). \\
(ii) \quad & (\ell(\lambda)(w, Y) \leq n) \iff (\exists (v_1, h_1) \in \partial [\Pi_{\downarrow}^{\lambda}](w) : Y \cap [\Pi_{\uparrow}^{\lambda}](v_1, h_1) \subseteq \bigcup_{i=1}^{n-1} \partial [\Phi_i^{\lambda}](Y)).
\end{align*}
\]

**Proof** (i) Let us assume that \( \ell(\lambda)(w, Y) \geq n \) and take \( (v_1, h_1) \in \partial [\Pi_{\uparrow}^{\lambda}](w) \). If we had \( [\Pi_{\uparrow}^{\lambda}](v_1, h_1) \cap Y \subseteq \bigcup_{i=1}^{n-2} \partial [\Phi_i^{\lambda}](Y) \), this quasi-paraboloid would not intersect...
Y after removing the first \((n - 2)\) layers, meaning that \(w\) would be at most of layer \((n - 1)\) so the first implication holds.

Conversely, let us assume that \([\Pi^\perp]^{(\lambda)}(v_1, h_1) \cap Y \not\subseteq \bigcup_{i=1}^{n-2} \partial[\Phi_i]^{(\lambda)}(Y)\). Then after removing the first \((n - 2)\) layers, any down quasi-paraboloid whose boundary contains \(w\) has to meet \(Y\). This implies that \(w\) is not extreme after removing the first \((n - 2)\) layers and thus \(\ell^{(\lambda)}(w, Y) \geq n\).

(ii) If \(\ell^{(\lambda)}(w, Y) = m \leq n\), \(w\) is extreme when we remove the first \((m - 1)\) layers. Thus let \((v_1, h_1) \in \partial[\Pi^\perp]^{(\lambda)}(w)\) be such that \([\Pi^\perp]^{(\lambda)}(v_1, h_1)\) does not contain any point of \(Y\) after removing the first \((m - 1)\) layers. This implies that

\[
[\Pi^\perp]^{(\lambda)}(v_1, h_1) \cap Y \subseteq \bigcup_{i=1}^{m-1} \partial[\Phi_i]^{(\lambda)}(Y) \subseteq \bigcup_{i=1}^{m-1} \partial[\Phi_i]^{(\lambda)}(Y).
\]

Conversely, if we assume that

\[
\exists (v_1, h_1) \in \partial[\Pi^\perp]^{(\lambda)}(w) : [\Pi^\perp]^{(\lambda)}(v_1, h_1) \cap Y \subseteq \bigcup_{i=1}^{m-1} \partial[\Phi_i]^{(\lambda)}(Y),
\]
either \(w\) belongs to the first \((n - 1)\) layers or it is extreme once the first \((n - 1)\) layers are removed. Thus \(\ell^{(\lambda)}(w, Y) \leq n\).

Lemma 2.6 below, which is of frequent use in our proofs, shows that the variables \(\ell^{(\lambda)}(w, X)\) are increasing with respect to the set \(X\). It slightly rephrases [20, Lemma 3.1] in the context of the parabolic hull peeling and [12, Lemma 2.1]. For sake of completeness, we include a short proof below.

**Lemma 2.6** For \(\lambda \in (0, \infty]\), if \(X \subset Y \subset W_\lambda\), we have for every \(w \in W_\lambda\), \(\ell^{(\lambda)}(w, X) \leq \ell^{(\lambda)}(w, Y)\).

**Proof** We prove the result by induction on \(n = \ell^{(\lambda)}(w, Y)\). When \(n = 1\), \(w\) is extreme for the point set \(Y \cup \{w\}\) so is also extreme for the smaller point set \(X \cup \{w\}\). When \(n > 1\), by Lemma 2.5 (ii), \(w\) lies on the boundary of a down quasi-paraboloid such that each point \(w'\) of \(Y\) in its interior satisfies \(\ell^{(\lambda)}(w', Y \cup \{w\}) \leq (n - 1)\). When \(w' \in X\), the induction hypothesis applied to \(w'\) and the point sets \(X \cup \{w\}\) and \(Y \cup \{w\}\) shows that \(\ell^{(\lambda)}(w', X \cup \{w\}) \leq \ell^{(\lambda)}(w', Y \cup \{w\}) \leq (n - 1)\). Consequently, using again Lemma 2.5 (ii), we obtain that \(\ell^{(\lambda)}(w, X) \leq n\). This completes the proof.

**Remark 2.7** In fact, when \(Y \setminus X\) is finite, we can show by arguments similar to the proof of [20, Lemma 3.1] that \(\ell^{(\lambda)}(w, Y) \leq \ell^{(\lambda)}(w, X) + \#(Y \setminus X)\) where \(\#(\cdot)\) denotes the cardinality, see Fig. 4.

Finally, we state without proof the counterparts of Lemmas 2.5 and 2.6 for the original convex hull peeling. To do so, following (2.8), for any \(X \subset \mathbb{R}^d\) and \(x \in \mathbb{R}^d\), we denote by \(\ell^x\) the number

\[
\ell^x(x, X) = n \text{ such that } x \in \partial \text{conv}_n(X \cup \{x\}).
\]

(2.9)

For any unit vector \(u \in S^{d-1}\) and any point \(x \in \mathbb{R}^d\), we also introduce the following half-space \(H^+_x = \{y \in \mathbb{R}^d : \langle y - x, u \rangle > 0\}\).
Fig. 4  The effect of adding a (red) point to the parabolic hull peeling. The red dashed lines are the changes applied to the layers (color figure online)

\textbf{Lemma 2.8} Let $x \in \mathbb{R}^d$, $X$ a locally finite subset of $\mathbb{R}^d$ and $n \geq 2$. Then we have the two following equivalences.

(i) $(\ell_X(x) \geq n) \iff (\forall u \in S^{d-1}, X \cap H^+_{x,u} \notin \bigcup_{i=1}^{n-2} \partial \text{conv}_i(X))$.

(ii) $(\ell_X(x) \leq n) \iff (\exists u \in S^{d-1} \text{ s.t. } X \cap H^+_{x,u} \subset \bigcup_{i=1}^{n-1} \partial \text{conv}_i(X))$.

\textbf{Lemma 2.9} If $x \in \mathbb{R}^d$ and $X \subset Y$ are two locally finite sets of $\mathbb{R}^d$ then $\ell_X(x) \leq \ell_Y(x)$.

\subsection*{2.3 Scores and correlation functions}

In this subsection we associate to each point of $\mathcal{B}_d$ (resp. $W_\lambda$) a random variable depending on that point and on the Poisson point process which we call a score. We start by defining the score of a point in the initial convex hull peeling before rescaling, i.e. for every $x \in \mathbb{B}_d$, $n \geq 1$ and $k \in \{0, \ldots, d-1\}$, we introduce the r.v.

$$\xi_{n,k}(x, X) := \begin{cases} \frac{1}{k+1} \# \mathcal{F}_{n,k}(x, X) & \text{if } x \in \partial \text{conv}_n(X \cup \{x\}) \\ 0 & \text{otherwise} \end{cases}$$

where $\mathcal{F}_{n,k}(x, X)$ is the set of all $k$-faces containing $x$ of $\partial \text{conv}_n(X \cup \{x\})$. The factor $\frac{1}{k+1}$ is needed to take into account the fact that the faces are counted multiple times since a $k$-face contains a.s. $(k + 1)$ points of $\mathcal{P}_\lambda$. In particular, we get the identity

$$N_{n,k,\lambda} = \sum_{x \in \mathcal{P}_\lambda} \xi_{n,k}(x, \mathcal{P}_\lambda).$$

We now extend this notion of score to the rescaled model. Let $\lambda \in (0, \infty]$, $Y$ be a locally finite subset of $\mathcal{W}_\lambda$, $w \in \mathcal{W}_\lambda$, $n \geq 1$ and $k \in \{0, \ldots, d-1\}$. We denote by $\mathcal{F}^{(\lambda)}_{n,k}(w, Y)$ the set of $k$-faces of $\partial \Phi^{(\lambda)}_{Y,\lambda}(Y \cup \{w\})$ containing $w$, i.e. the image by $T^{(\lambda)}$ of the set of $k$-faces of $\text{conv}_n([T^{(\lambda)}]^{-1}(Y \cup \{w\}))$ containing $[T^{(\lambda)}]^{-1}(w)$ when $\lambda < \infty$. When $\lambda = \infty$, $\mathcal{F}^{(\lambda)}_{n,k}(w, Y)$ is the set of $k$-dimensional parabolic faces of
\( \Phi_{n,k}^\lambda(Y \cup \{w\}) \), as defined in [13, p. 65–66], containing \( w \). For any fixed \( \lambda \in (0, \infty) \), we define the score

\[
\xi_{n,k}^{(\lambda)}(w, Y) := \begin{cases} 
\frac{1}{k+1} \# F_{n,k}^{(\lambda)}(w, Y) & \text{if } w \in \partial \Phi_{n,k}^{(\lambda)}(Y \cup \{w\}) \\
0 & \text{otherwise}
\end{cases}.
\] (2.11)

We deduce from (2.11) and (2.7) that for every \( w \in W_\lambda \),

\[
\xi_{n,k}^{(\lambda)}(w, \mathcal{P}^{(\lambda)}) = \xi_{n,k}^{(\lambda)}([T^{(\lambda)}]^{-1}(w), \mathcal{P}_\lambda).
\] (2.12)

Note that the r.v. \( \xi_{n,k}^{(\lambda)} \) are calibrated such that \( \sum_{w \in \mathcal{P}^{(\lambda)}} \xi_{n,k}^{(\lambda)}(w, \mathcal{P}^{(\lambda)}) \) is a.s. the total number of \( k \)-faces of \( \partial \Phi_{n,k}^{(\lambda)}(\mathcal{P}^{(\lambda)}) \).

We then introduce the two-point correlation function which is crucial for deriving the limiting variance. For any \( \lambda \in (0, \infty) \) let us write

\[
c_{n,k}^{(\lambda)}((0, h_0), (v_1, h_1)) := \mathbb{E}[\xi_{n,k}^{(\lambda)}((0, h_0), \mathcal{P}^{(\lambda)} \cup \{(v_1, h_1)\})\xi_{n,k}^{(\lambda)}((v_1, h_1), \mathcal{P}^{(\lambda)} \cup \{(0, h_0)\})] - \mathbb{E}[\xi_{n,k}^{(\lambda)}((0, h_0), \mathcal{P}^{(\lambda)})]\mathbb{E}[\xi_{n,k}^{(\lambda)}((v_1, h_1), \mathcal{P}^{(\lambda)})].
\] (2.13)

We conclude by giving a more precise statement of Theorem 1.1, as we have now introduced every notation involved in the limiting constants.

**Theorem 2.10** For any \( n \geq 1 \) and \( k \in \{0, \ldots, d-1\} \) we have

\[
\lim_{\lambda \to \infty} \lambda^{-\frac{d-1}{d+1}} \mathbb{E}[N_{n,k,\lambda}] = \text{Vol}_{d-1}(\mathbb{S}^{d-1}) \int_0^{+\infty} \mathbb{E}[\xi_{n,k}^{(\infty)}((0, h), \mathcal{P})]dh \in (0, \infty).
\]

**Theorem 2.11** For any \( n \geq 1 \) and \( k \in \{0, \ldots, d-1\} \) we have

\[
\lim_{\lambda \to \infty} \lambda^{-\frac{d-1}{d+1}} \text{Var}[N_{n,k,\lambda}] = \text{Vol}_{d-1}(\mathbb{S}^{d-1}) \left( I_1 + I_2 \right) \in (0, \infty)
\]

where

\[
I_1 := \int_0^{+\infty} \mathbb{E}[\xi_{n,k}^{(\infty)}((0, h), \mathcal{P})^2]dh
\] (2.14)

and

\[
I_2 := \int_0^{+\infty} \int_0^{+\infty} \int_{\mathbb{S}^{d-1}} c_{n,k}^{(\infty)}((0, h_0), (v_1, h_1))dv_1dh_0dh_1.
\] (2.15)

We restate in a similar way Theorem 1.2 for the intrinsic volumes, using the definitions of \( \xi_{V,n,k}^{(\infty)} \) and \( c_{V,n,k}^{(\infty)} \) introduced at (5.14) and (5.15) respectively.
Theorem 2.12 For any $n \geq 1$ and $k \in \{1, \ldots, d\}$ we have
\[
\lim_{\lambda \to +\infty} \lambda^{2/2d+1} \mathbb{E}[V_{n,k,\lambda}] = \text{Vol}_{d-1}(S^{d-1}) \int_0^{+\infty} \mathbb{E}[\xi_{V,n,k}^{(\infty)}((0,h),\mathcal{P})]dh \in (0, \infty).
\]

Theorem 2.13 For any $n \geq 1$ and $k \in \{1, \ldots, d\}$ we have
\[
\lim_{\lambda \to +\infty} \lambda^{d/2d+1} \text{Var}[V_{n,k,\lambda}] = \text{Vol}_{d-1}(S^{d-1}) (I_1 + I_2) \in (0, \infty)
\]
where
\[
I_1 := \int_0^{+\infty} \mathbb{E}[\xi_{V,n,k}^{(\infty)}((0,h),\mathcal{P})^2]dh
\]
and
\[
I_2 := \int_0^{+\infty} \int_0^{+\infty} \int_{\mathbb{R}^{d-1}} c^{(\infty)}_{V,n,k}((0,h_0),(v_1,h_1))dv_1dh_0dh_1.
\]

3 Stabilization

The aim of this section is to show stabilization results for the considered scores. This means roughly that the score calculated at one particular fixed point requires the knowledge of the Poisson points outside of a lateral neighborhood of that fixed point with an exponentially decreasing probability. This tool is essential to get moment bounds in Lemma 4.1, then the convergence of the mean of one score and of the covariance of the scores and ultimately our main results, i.e Theorems 1.1 and 1.2.

3.1 Local scores and stabilization radius

First we extend the notion of score to a local score in an angular sector around a point in the following way. For $x \in \mathbb{B}^d$ and $r > 0$, we introduce $S(x,r) = \{y \in \mathbb{R}^d : d_{S^{d-1}}(x/\|x\|, y/\|y\|) \leq r\}$ where $d_{S^{d-1}}$ is the geodesic distance along $S^{d-1}$ and
\[
\xi_{n,k,[r]}(x, \mathcal{P}_\lambda) := \xi_{n,k}(x, \mathcal{P}_\lambda \cap S(x,r)).
\]
We define the stabilization radius in the initial model as
\[
R_{n,k}(x, \mathcal{P}_\lambda) := \inf\{R > 0 : \xi_{n,k}(x, \mathcal{P}_\lambda) = \xi_{n,k,[r]}(x, \mathcal{P}_\lambda) \forall r \geq R\}.
\]
In particular, thanks to the rotation invariance of $\mathcal{P}_\lambda$, we get the identity in law
\[
R_{n,k}(x, \mathcal{P}_\lambda) \overset{(d)}{=} R_{n,k}(\|x\|e_d, \mathcal{P}_\lambda).
\]
We formally introduce the stabilization radius in the rescaled model as

\[ R_{n,k}^{(\lambda)}(w, \mathcal{P}^{(\lambda)}) := R_{n,k}([T^{(\lambda)}]^{-1}(w), \mathcal{P}_\lambda). \]  

(3.2)

Combining (3.2) with (3.1), we obtain the invariance under horizontal translation of \( R_{n,k}^{(\lambda)} \), namely for any \((v, h) \in W_\lambda,\):

\[ R_{n,k}^{(\lambda)}((v, h), \mathcal{P}^{(\lambda)}) \equiv R_{n,k}^{(\lambda)}((0, h), \mathcal{P}^{(\lambda)}). \]  

(3.3)

Since the image by \( T^{(\lambda)} \) of \( S(e_d, r) \) for \( r \in (0, \pi) \) is a cylinder, we also extend the notion of score in the rescaled picture to a local score in a cylinder of radius \( r \) around a point in the following way. For any \( r > 0, \lambda \in (0, \infty] \) and \( w = (v, h) \in W_\lambda \) we write

\[ \xi_{n,k,[r]}^{(\lambda)}(w, \mathcal{P}^{(\lambda)}) := \xi_{n,k}^{(\lambda)}(w, \mathcal{P}^{(\lambda)} \cap C_v(r)). \]  

(3.4)

When \( w = (0, h) \), the following equality provides a convenient expression of the stabilization radius, which is the one we use most of the time:

\[ R_{n,k}^{(\lambda)}((0, h), \mathcal{P}^{(\lambda)}) = \inf \{ R > 0 \mid \exists \lambda \xi_{n,k}^{(\lambda)}((0, h), \mathcal{P}^{(\lambda)}) = \xi_{n,k,[r]}^{(\lambda)}((0, h), \mathcal{P}^{(\lambda)}) \forall r \geq R \}. \]

We provide estimates for the distribution tail of \( R_{n,0}^{(\lambda)}(w, \mathcal{P}^{(\lambda)}) \) in Sect. 3.2 and of \( R_{n,k}^{(\lambda)}(w, \mathcal{P}^{(\lambda)}) \) in Sect. 3.3.

### 3.2 Stabilization for points

A prerequisite for Sects. 3.2 and 3.3 is the following geometric lemma that we will use extensively when showing the stabilization property. Though standard, we include its proof below for the reader’s convenience.

**Lemma 3.1** Let \( \lambda \in (0, \infty] \) and \( w_0, w_1 \in H \) such that \( \partial [\Pi^{\perp}(w_1)](w_0) \) goes through \( w_0 \). Then there exists a half-space \( P^+ \) delimited by a hyperplane \( P \) going through \( w_0 \) with direction containing \((0, 0, \ldots, 0, 1)\) such that \( [\Pi^{\perp}](w_0) \cap P^+ \subseteq [\Pi^{\perp}](w_1) \).

**Proof** For finite \( \lambda \), this is a direct consequence of the following fact in the non-rescaled model: for any point \( x_0 = re_d, r \in (0, 1) \) and any point \( x_1 \in \partial B(x_0, \|x_0\|/2) \), the set \( \text{cap}(x_1) \) as defined in (2.2) contains at least half of \( \text{cap}(x_0) \). Using (2.3) and (2.5), we deduce the required result in the rescaled model.

For \( \lambda = \infty \), we proceed along the following lines. An orthogonal transformation allows us to assume that \( w_0 = (0, 0, \ldots, 0, h_0) \) for some \( h_0 > 0 \) and \( w_1 = (a, 0, \ldots, 0, h_1) \) with \( a, h_1 > 0 \). Since \( \partial \Pi^{\perp}(w_1) \) goes through \( w_0 \), we must have \( a = \sqrt{2(h_1 - h_0)} \). Let us show that \( \Pi^{\perp}(w_0) \cap \{(v, h) : (v)_1 > 0\} \subseteq \Pi^{\perp}(w_1) \) where \((v)_1, \ldots, (v)_{d-1}\) denote the consecutive coordinates of \( v \). The equations of both paraboloids are
\[ \Pi^\downarrow(w_0) : (h < h_0 - \frac{1}{2} \sum_{i=1}^{d-1} (v^2) ) \]

and \[ \Pi^\downarrow(w_1) : (h < h_1 - \frac{1}{2} (((v) - a)^2 + \sum_{i=2}^{d-1} (v^2) )) . \]

For \((v, h) \in \Pi^\downarrow(w_0) \cap \{(v, h) : (v)_1 > 0\}\), using \(a = \sqrt{2(h_1 - h)}\), we get

\[
h < h_0 - \frac{1}{2} (((v)_1 - a)^2 + \sum_{i=2}^{d-1} (v^2) ) + \frac{1}{2} \sqrt{2(h_1 - h_0)^2} - a(v)_1
\]

\[
< h_1 - \frac{1}{2} (((v)_1 - a)^2 + \sum_{i=2}^{d-1} (v^2) )
\]

This completes the proof. \(\square\)

In the next lemma we show that the maximal height of the Poisson points on the \(n\)-th layer \(\partial \Phi_1^{(\lambda)}\) of the quasi-parabolic hull peeling inside a cylinder is bounded with a probability going to 1 exponentially fast with respect to the bound. This will be essential for proving the stabilization result in Proposition 3.3 and will also be useful when proving Lemma 3.5 which provides a stabilization in height.

Here and in the sequel we denote by \(c, c_1, c_2, \ldots\) generic positive constants that only depend on \(n, k\) and \(d\) and which may change from line to line.

**Lemma 3.2** For all \(n \geq 1\), there exist \(\lambda_0, c_1, c_2 > 0\) such that for all \(t \geq 0, \lambda \in [\lambda_0, \infty]\) and \(1 \leq r < \pi \lambda \frac{1}{d+1}\), we have

\[
\mathbb{P}\left( \exists (v, h) \in \mathcal{P}^{(\lambda)} \cap \partial \Phi_n^{(\lambda)} \left( \mathcal{P}^{(\lambda)} \cap C(r) \right) \cap C(r/2^n) \text{ with } h \geq t \right) \leq c_1 r^{n(d-1)} e^{-c_2 t(r / \sqrt{t})^{d-1}}
\]

and

\[
\mathbb{P}\left( \exists (v, h) \in \mathcal{P}^{(\lambda)} \cap \partial \Phi_n^{(\lambda)} \left( \mathcal{P}^{(\lambda)} \right) \cap C(r/2^n) \text{ with } h \geq t \right) \leq c_1 r^{n(d-1)} e^{-c_2 t(r / \sqrt{t})^{d-1}}.
\]

**Proof** We only prove the first inequality as the method for getting the second one is very similar.

We begin with the proof for \(\lambda = \infty\) as the case \(\lambda < \infty\) is a bit more technical. We are going to show it by induction on \(n\). We first prove the induction step as it contains the main ideas. Then we describe what needs to be changed to prove the induction step for \(\lambda < \infty\) and finally we explain the slight modifications that are needed to prove the base case.
Proof of the induction step for \( \lambda = \infty \). We assume that the result holds for all \( l < n \) with a fixed \( n > 1 \) and we show that it holds for \( n \).

Let \( w = (v, h) \in C(r/2^n) \) with \( h \geq t \). Our first step is to show that the event

\[
\{w \in \partial \Phi_n ((\mathcal{P} \cup \{w\}) \cap C(r))\} \tag{3.5}
\]

occurs with probability smaller than \( c_1 \exp(-c_2 h (r \wedge \sqrt{h})^{d-1}) \). Here we add \( w \) to the point process because we plan to use Mecke’s formula later to deal with a union over all \( w \).

Let \( (v_1, h_1) \in \mathbb{R}^{d-1} \times \mathbb{R}_+ \) such that \( w \in \partial \Pi^1(v_1, h_1) \) and \( \Pi^1(v_1, h_1) \) only contains points of layer at most \((n-1)\) for \( C(r) \). Lemma 2.5 (ii) guarantees that such a \((v_1, h_1)\) exists.

By Lemma 3.1, this downward paraboloid contains at least half of \( \Pi^1(w) \). Consequently, denoting by \( A_1, \ldots, A_{2^{d-1}} \) the intersections of \( \Pi^1(w) \) with the product of an orthant of \( \mathbb{R}^{d-1} \) translated by \( v \) with \( \mathbb{R}_+ \), we have

\[
\text{Vol}_d(\Pi^1(w) \cap C_{2} \cap (r/2^n)) = \frac{1}{2^n} \text{Vol}_d(\Pi^1(w) \cap C_{2 \wedge h} \cap (r/2^n)) \text{ and } \Pi^1(v_1, h_1) \text{ contains at least one of the } A_i.
\]

Let us write

\[
B_{i,n}(h, r) := A_i \cap \{(v', h') : h' \geq h/2 \} \cap C(r/2^n - 1). \tag{3.6}
\]

From the preceding reasoning we deduce that

\[
\{w \in \partial \Phi_n ((\mathcal{P} \cup \{w\}) \cap C(r))\} \subseteq \{\exists i : \mathcal{P} \cap B_{i,n}(h, r) \subseteq [\Phi_n((\mathcal{P} \cup \{w\}) \cap C(r))]^c\}.
\]

For fixed \( i \), \( B_{i,n}(h, r) \) is either empty, which happens with probability smaller than \( c_1 \exp(-c_2 h (r \wedge \sqrt{h})^{d-1}) \) or it contains a point at height larger than \( h/2 \) on a layer at most \((n-1)\), which happens with probability smaller than \( c_1 r^{(n-1)(d-1)} \exp(-c_2 h (r \wedge \sqrt{h})^{d-1}) \) by the induction hypothesis. Consequently we have

\[
\mathbb{P}(\{w \in \partial \Phi_n ((\mathcal{P} \cup \{w\}) \cap C(r))\} \leq c_1 r^{(n-1)(d-1)} \exp(-c_2 h (r \wedge \sqrt{h})^{d-1}). \tag{3.7}
\]

We can write

\[
\mathbb{P}(\exists(v, h) \in \mathcal{P} \cap \partial \Phi_n (\mathcal{P} \cap C(r)) \cap C(r/2^n) \text{ with } h \geq t) \leq \mathbb{E} \left[ \sum_{w \in \mathcal{P} \cap C(r/2^n)} 1_{w \in \partial \Phi_n (\mathcal{P} \cap C(r))} \right].
\]

We combine this with Mecke’s formula and (3.7) to get

\[
\mathbb{P}(\exists(v, h) \in \mathcal{P} \cap \partial \Phi_n (\mathcal{P} \cap C(r)) \cap C(r/2^n) \text{ with } h \geq t) \leq \int_{\|v\| \leq r/2^n} \int_{h \in [t, +\infty)} \mathbb{P}(\{(v, h) \in \partial \Phi_n ((\mathcal{P} \cup \{(v, h)\}) \cap C(r))\}) \, dh \, dv.
\]

\[
\leq \int_{\|v\| \leq r/2^n} \int_{h \in [t, +\infty)} c_1 r^{(n-1)(d-1)} \exp(-c_2 h (r \wedge \sqrt{h})^{d-1}) \, dh \, dv.
\]
This proves the induction step.

Proof of the induction step for $\lambda < \infty$.

Let us check that the proof above still holds. The only difference here is that the intensity of the process is no longer constant. However let us recall that this intensity has a density given by (2.1) so it is uniformly bounded from below for any $\|v\| \leq \frac{3}{4} \lambda \pi \frac{1}{d+1}$ and $h \leq \frac{3}{4} \lambda \frac{2}{d+1}$ by a constant that does not depend on $\lambda$ and is upper bounded by 1.

The same proof as in the case $\lambda = \infty$ shows that

$$\left\{ w \in \partial \Phi_1^{(\lambda)} \left( (\mathcal{P}^{(\lambda)} \cup \{w\} ) \cap C(r) \right) \right\} \subseteq \left\{ \exists i : \mathcal{P}^{(\lambda)} \cap B_{i,n}(h,r) \subseteq [\Phi_n^{(\lambda)}((\mathcal{P}^{(\lambda)} \cup \{w\}) \cap C(r))]^{c} \right\}.$$ 

with $B_{i,n}(h,r)$ introduced at (3.6). If for a fixed $i$, $B_{i,n}(h,r)$ is empty then in particular the set $B_{i,n}(h,r) \cap \{(v',h') : \frac{1}{2} h \leq h' \leq \frac{3}{4} h \} \cap C(r/2^{n-1})$ is also empty and included in the region $\{(v',h') : \|v\| \leq \frac{3}{4} \lambda \pi \frac{1}{d+1}$ and $h' \leq \frac{3}{4} \lambda \frac{2}{d+1}\}$ on which the density at (2.1) is bounded from below by a constant. Consequently,

$$\mathbb{P}(\mathcal{P}^{(\lambda)} \cap B_{i,n}(h,r) = \emptyset) \leq e^{-c_1 \text{Vol}_d(B_{i,n}(h,r))} \leq e^{-c_2 h(r \wedge \sqrt{h})^{d-1}}.$$ 

The use of the induction hypothesis remains unchanged so we still have (3.7) in the case $\lambda < \infty$. To get the result we then follow the same steps as before except that we upper-bound the intensity density by 1 after the use of Mecke’s formula.

Proof of the base case $n = 1$ for both $\lambda = \infty$ and $\lambda < \infty$.

We define for every $1 \leq i \leq 2^{d-1}$

$$\tilde{B}_{i,1}(h,r) = A_i \cap \left\{ (v',h') : \frac{1}{2} h \leq h' \leq \frac{3}{4} h \right\} \cap C(3r/4).$$

which guarantees that the intensity measure of $\tilde{B}_{i,1}(h,r)$ is lower bounded by its Lebesgue measure up to a multiplicative constant. Using the inclusion

$$\left\{ w \in \partial \Phi_1 \left( (\mathcal{P}^{(\lambda)} \cup \{w\} ) \cap C(r) \right) \right\} \subseteq \left\{ \exists i : \mathcal{P}^{(\lambda)} \cap \tilde{B}_{i,1}(h,r) = \emptyset \right\},$$

we get an analogue of (3.7) which, combined with Mecke’s formula, proves the base case.

This completes the proof of Lemma 3.2. \qed

We are now ready to prove a stabilization result for the $0-$faces, i.e. the extreme points of the $n-$th layer. It is a crucial step towards a general stabilization for $k-$faces.
Proposition 3.3  For all $n \geq 1$, there exist $\lambda_0, c_1, c_2 > 0$ such that for any $h_0 > 0$, $\lambda \in [\lambda_0, +\infty)$ and $1 \leq r < \pi \lambda^{\frac{1}{d+1}}$ we have

$$\mathbb{P}\left(R^{(\lambda)}_{n,0}(0, h_0) \geq r\right) \leq c_1 \exp(-c_2 r^{d+1}). \quad (3.8)$$

Proof  We give a detailed proof for the case $\lambda = \infty$ and briefly describe at the end how to adapt the proof to make it work for finite $\lambda$.

We show this result by induction. The case $n = 1$ corresponds to [13, Lemma 6.1]. We now fix $n \geq 2$ and assume that (3.8) is verified for all $m < n$. Let us show (3.8) for $n$.

We first notice that

$$\{R^{(\lambda)}_{n,0}(0, h_0) \geq r\} = \bigcup_{s \geq r} \left\{ \xi^{(\infty)}_{n,0} ((0, h_0), \mathcal{P} \cap C(s)) \neq \xi^{(\infty)}_{n,0} ((0, h_0), \mathcal{P}) \right\}.$$ 

Let us introduce

$$E_1 := \bigcup_{s \geq r} \bigcup_{l < n} \{(0, h_0) \in \partial \Phi_l (\mathcal{P} \cap C(s)) \cap \partial \Phi_n (\mathcal{P})\},$$

$$E_2 := \bigcup_{s \geq r} \bigcup_{l > n} \{(0, h_0) \in \partial \Phi_n (\mathcal{P} \cap C(s)) \cap \partial \Phi_l (\mathcal{P})\}.$$ 

Since $\{R^{(\lambda)}_{n,0}(0, h_0) \geq r\} = E_1 \cup E_2$, it is enough to prove that for any $r \geq 1$, 

$$\mathbb{P}(E_1) \leq c_1 \exp(-c_2 r^{d+1}) \quad (3.9)$$

and

$$\mathbb{P}(E_2) \leq c_1 \exp(-c_2 r^{d+1}). \quad (3.10)$$

Decomposition of $E_1$. The strategy is the following: we plan to select a down-paraboloid which contains $(0, h_0)$ on its boundary and a point $w$ in its interior to which we can apply the induction hypothesis, recalling (3.3).

To do so, we introduce the two events

$$F_1 := \{ \exists (v_1, h_1) \in \partial \Pi^\dagger (0, h_0), \ h_1 \leq r^2/32 \} : \mathcal{P} \cap C(r) \cap \Pi^\dagger (v_1, h_1) \subseteq [\Phi_{n-1} (\mathcal{P} \cap C(r))]^c \cap \{(0, h_0) \in \partial \Phi_n (\mathcal{P})\},$$

$$F_2 := \{ \exists (v_1, h_1) \in \partial \Pi^\dagger (0, h_0), \ h_1 \geq r^2/32 \} : \mathcal{P} \cap C(r) \cap \Pi^\dagger (v_1, h_1) \subseteq [\Phi_{n-1} (\mathcal{P} \cap C(r))]^c \cap \{(0, h_0) \in \partial \Phi_n (\mathcal{P})\},$$

see Fig. 5.

When $n = 2$, we replace the inclusion $\mathcal{P} \cap C(r) \cap \Pi^\dagger (v_1, h_1) \subseteq [\Phi_{n-1} (\mathcal{P} \cap C(r))]^c$ in the definition of $F_1$ and $F_2$ above by $\mathcal{P} \cap C(r) \cap \Pi^\dagger (v_1, h_1) = \emptyset$. 

\[ Springer \]
In particular, \( E_1 \subseteq F_1 \cup F_2 \). Indeed if one of the events of the union in the definition of \( E_1 \) occurs for fixed \( l < n \) and \( s \geq r \), there exists \((v_1, h_1) \in \partial \Pi^\uparrow(0, h_0)\) such that for every \( w \in \mathcal{P} \cap C(r) \cap \Pi^\uparrow(v_1, h_1)\), \( \ell(\infty)(w, \mathcal{P} \cap C(s)) \leq (l - 1) \). Lemma 2.6 then implies that \( \ell(\infty)(w, \mathcal{P} \cap C(r)) \leq (l - 1) \leq (n - 2) \) for any such \( w \).

Consequently, it suffices to upper bound \( \mathbb{P}(F_1) \) and \( \mathbb{P}(F_2) \) which we do with two different strategies. In the case of \( F_1 \), there is a downward paraboloid \( \Pi^\downarrow(v_1, h_1) \) which is low enough to be contained in a cylinder smaller than \( C(r) \). This implies that we can apply the induction hypothesis to a well chosen point in \( \Pi^\downarrow(v_1, h_1) \).

When on \( F_2 \), the downward paraboloid is high enough so that there is a high point \( w \) with \( \ell(\infty)(w, \mathcal{P} \cap C(r)) \leq n \) and we deduce from Lemma 3.2 that it happens with exponentially small probability.

**Upper bound for \( \mathbb{P}(F_1) \).** Let us fix \((v_1, h_1)\) with \( h_1 \leq r^2/32 \) as in the event \( F_1 \).

Using that \((v_1, h_1) \in \partial \Pi^\uparrow(0, h_0)\), we get

\[
\|v_1\| = \sqrt{2(h_1 - h_0)} \leq \sqrt{2h_1} = r/4.
\]  

(3.11)

Furthermore if we take \((v_2, h_2) \in \Pi^\downarrow(v_1, h_1)\), the norm of \( v_2 \) is smaller than the norm of \( v_1 \) plus half of the width of the paraboloid \( \Pi^\downarrow(v_1, h_1)\), so

\[
\|v_2\| \leq \|v_1\| + \|v_2 - v_1\| \leq \frac{r}{4} + \sqrt{2h_1} \leq r/2.
\]

(3.12)

This implies that \( \Pi^\downarrow(v_1, h_1) \subseteq C(r/2) \). In particular, when \( n = 2 \), we get that \((0, h_0)\) is an extremal point of \( \mathcal{P} \cup \{(0, h_0)\} \) and subsequently that \( F_1 = \emptyset \). In the case \( n > 2 \), we proceed in the following way. Since \( \ell(\infty)((0, h_0), \mathcal{P}) = n \), we can choose a point \( w \in \Pi^\downarrow(v_1, h_1) \) such that \( \ell(\infty)(w, \mathcal{P}) \geq (n - 1) \).
Then because we are on the event $F_1$, we also have $\ell^{(\infty)}(w, \mathcal{P} \cap C(r)) \leq (n - 2)$. By Lemma 2.6, this implies that $\ell^{(\infty)}(w, \mathcal{P} \cap C_w(r/2)) \leq (n - 2)$, which means that

$$\exists m \leq (n - 2) : R_{m,0}^{(\infty)}(w) \geq r/2. \quad (3.13)$$

Using the induction hypothesis

$$\mathbb{P}(R_{m,0}^{(\infty)}(w) \geq r/2) \leq c_1 \exp(-c_2r^{d+1}).$$

Since $w$ belongs to $\mathcal{P} \cap C \lesssim \frac{x}{r^2}(r/2)$, we rewrite

$$\mathbb{P}(F_1) \leq \mathbb{P}\left(\bigcup_{m=1}^{n-2} \bigcup_{w \in \mathcal{P} \cap C \lesssim \frac{x}{r^2}(r/2)} \{R_{m,0}^{(\infty)}(w, \mathcal{P}) \geq r/2\}\right) \leq \mathbb{E}\left[\sum_{m=1}^{n-2} \sum_{w \in \mathcal{P} \cap C \lesssim \frac{x}{r^2}(r/2)} \mathbb{1}_{\{R_{m,0}^{(\infty)}(w, \mathcal{P}) \geq r/2\}}\right].$$

Now we use Mecke’s formula to obtain

$$\mathbb{P}(F_1) \leq \sum_{m \leq n - 2} \int_{C \lesssim \frac{x}{r^2}(r/2)} \mathbb{P}\left(R_{m,0}^{(\infty)}(w, \mathcal{P}) \geq r/2\right) dw \leq c_1 \exp(-c_2r^{d+1}). \quad (3.14)$$

**Decomposition of $F_2$.**

We rewrite $F_2 = G_1 \cup G_2$ where

$$G_1 := \{\exists (v_1, h_1), \ h_1 \geq r^2/32, \ ||v_1|| \leq r/6 : \ \mathcal{P} \cap C(r) \cap \Pi^\perp(v_1, h_1) \subseteq [\Phi_{n-1}(\mathcal{P} \cap C(r))]^c \cap \{(0, h_0) \in \partial \Phi_n(\mathcal{P})\}.$$

$$G_2 := \{\exists (v_1, h_1), \ h_1 \geq r^2/32, \ ||v_1|| \geq r/6 : \ \mathcal{P} \cap C(r) \cap \Pi^\perp(v_1, h_1) \subseteq [\Phi_{n-1}(\mathcal{P} \cap C(r))]^c \cap \{(0, h_0) \in \partial \Phi_n(\mathcal{P})\}.$$

Again, when $n = 2$, we replace the inclusion $\mathcal{P} \cap C(r) \cap \Pi^\perp(v_1, h_1) \subseteq [\Phi_{n-1}(\mathcal{P} \cap C(r))]^c$ in the definition of $F_1$ and $F_2$ above by $\mathcal{P} \cap C(r) \cap \Pi^\perp(v_1, h_1) = \emptyset$.

**Upper bound for $\mathbb{P}(G_1)$.** We fix $(v_1, h_1)$ with $||v_1|| \leq r/6$ and $h_1 \geq r^2/32$ as in the event $G_1$. In particular, we get

$$h_0 = h_1 - \frac{||v_1||^2}{2} \geq \frac{5}{288}r^2. \quad (3.15)$$

By Lemma 3.1, the down-paraboloid $\Pi^\perp(v_1, h_1)$ contains half of $\Pi^\perp(0, h_0) \cap C \lesssim \frac{x}{r^2}(\frac{r^2}{288})$, see Fig. 6 (left). As in the proof of Lemma 3.2, we can find a deterministic
subset $A_i$ of $\Pi(0, h_0)$ for some $1 \leq i \leq 2^{d-1}$ such that $A_i \subseteq \Pi(v_1, h_1)$ and

$$\text{Vol}_d \left( A_i \cap C \left( \frac{r_0}{2n} \right) \right) = \frac{1}{2^{d-1}} \text{Vol}_d \left( \Pi(0, h_0) \cap C \left( \frac{r_0}{2n} \right) \right). \quad (3.16)$$

The set $A_i \cap C \left( \frac{h_0}{2n} \right)$ is empty with probability bounded by $\exp(-cr^{d+1})$ thanks to (3.15) and (3.16). If $A_i \cap C \left( \frac{h_0}{2n} \right)$ is not empty, which happens only when $n \geq 3$, it contains a point $w$ at height at least $\frac{h_0}{2} \geq cr^2$ with $\ell(\infty)(w, \partial C(r)) \leq (n-2)$.

Using Lemma 3.2 this happens with probability smaller than $c_1 \exp(-c_2r^{d+1})$.

A union bound on the finite number of sets $A_1, \ldots, A_{2^{d-1}}$ yields

$$\mathbb{P}(G_1) \leq c_1 \exp(-c_2r^{d+1}). \quad (3.17)$$

**Upper bound for $\mathbb{P}(G_2)$**. We fix $(v_1, h_1)$ with $\|v_1\| \geq r/6$ and $h_1 \geq r^2/32$ as in the event $G_2$. Let $P$ be the vertical plane containing the origin and $(v_1, h_1)$ and let $(v_2, h_2)$ be the highest intersection point between $\Pi(v_1, h_1)$ and $\partial C(r/2n+1)$ in $P$. Using $\|v_1\| = \sqrt{2(h_1 - h_0)}$, we get

$$h_2 = h_1 - \frac{1}{2} \left( \|v_1\| - \frac{r}{2n+1} \right)^2 = h_0 + \frac{r}{2n+1} \sqrt{2(h_1 - h_0)} - \frac{r^2}{2(2n+1)^2} \geq cr^2. \quad (3.18)$$

We claim that $\Pi(v_1, h_1) \cap C \left( \frac{h_2}{2n+1} \right)$ contains a deterministic cylinder $C_0$ with width proportional to $r$ and height proportional to $h_2$. Indeed, for $n \geq 3$, the cylinder inscribed in $C \left( \frac{r}{2n+1} \right)$ of radius $\frac{r}{2n+2}$ between heights $\frac{h_2}{2}$ and $h_2$ and with axis included in $P$ as in Fig. 6 is fully included in $\Pi(v_1, h_1)$, thanks to the inequality $\|v_1\| \geq \frac{r}{6} \geq \frac{h_0}{2n}$. For $n = 2$, the inequality is not satisfied and that is why we take a thinner cylinder inscribed in $C \left( \frac{r}{6} \right)$ instead.
The cylinder $C_0$ constructed above is empty with probability smaller than $\exp(-ch_2r^{d-1})$. If $C_0$ is not empty, which happens only when $n \geq 3$, it contains a point $w$ of height at least $h_2^n$ with $\ell(\infty)(w, \mathcal{P} \cap C(r)) \leq (n-2)$. By Lemma 3.2 combined with (3.18), this happens with probability smaller than $c_1r^{d-1}\exp(-c_2h_2r^{d-1})$.

Finally, discretizing $\partial \Pi(0, h_0)$ for

$$h_1 \geq h_0 + \frac{1}{2} \left(\frac{r}{6}\right)^2,$$

we get

$$\mathbb{P}(G_2) \leq c_1 \int_{h_0+r^2/\sqrt{2}}^{\infty} (h_1 - h_0)^{(d-2)/2} e^{-c_2(h_0 + \frac{r}{2\sqrt{2}} \sqrt{2(h_1-h_0)} - \frac{r^2}{2(2\sqrt{2})^2})} r^{d-1} dh_1$$

$$\leq c_1 \int_{h_0+r^2/\sqrt{2}}^{\infty} (h_1 - h_0)^{(d-2)/2} e^{-c_2 \frac{r}{2\sqrt{2}} \sqrt{2(h_1-h_0)} r^{d-1}} dh_1$$

$$\leq c_1 \exp(-c_2r^{d+1}).$$

**Conclusion for $\lambda = \infty$.** Using the inclusion $E_1 \subset F_1 \cup G_1 \cup G_2$ and the estimates for $\mathbb{P}(F_1)$, $\mathbb{P}(G_1)$ and $\mathbb{P}(G_2)$ obtained above, we deduce (3.9). The estimate (3.10) is obtained in a very similar fashion, where $n$ plays the role of $l$, by considering the decomposition $E_2 \subset F'_1 \cup F'_2$ where

$$F'_1 = \{\exists (v_1, h_1) \in \partial \Pi(0, h_0), h_1 \leq r^2/32 : \mathcal{P} \cap C(r) \cap \Pi(0, h_0) \subseteq [\Phi_n(\mathcal{P} \cap C(r))]^c \cap [\exists l > n, (0, h_0) \in \partial \Phi_l(\mathcal{P})]\},$$

$$F'_2 = \{\exists (v_1, h_1) \in \partial \Pi(0, h_0), h_1 \geq r^2/32 : \mathcal{P} \cap C(r) \cap \Pi(0, h_0) \subseteq [\Phi_n(\mathcal{P} \cap C(r))]^c \cap [\exists l > n, (0, h_0) \in \partial \Phi_l(\mathcal{P})]\}.$$

For the sake of brevity, the proof of (3.10) is omitted. Combining (3.9) and (3.10), we complete the proof of Proposition 3.3 when $\lambda = \infty$.

**Case $\lambda < \infty$.** We recall the two necessary updates for finite $\lambda$.

1. **Density.** The density of the intensity measure of $\mathcal{P}(\lambda)$ is lower bounded by a positive constant in a compact subset of $W_\lambda$ only.

2. **Quasi-paraboloids.** The calculations that have been done with paraboloids are valid for quasi-paraboloids up to a small error.

The second update above implies that for $\lambda$ large enough, (3.11) and (3.12) can be replaced by $\|v_1\| \leq \frac{r}{3}$ and $\|v_2\| \leq \frac{2r}{3}$ respectively. The assertion (3.13) is in turn replaced by $R_n(w) \geq r/3$ for some $m \leq (n-2)$ and we proceed with the same reasoning as before to get (3.14).

Regarding the upper bounds of $\mathbb{P}(G_1)$ and $\mathbb{P}(G_2)$, we make the following modifications.

- Because of the second update, the inequalities (3.15), (3.18) and (3.19) deduced from the actual equation of a paraboloid become $h_0 \geq cr^2$, $h_2 \geq cr^2$ and $h_1 \geq$
\( h_0 + cr^2 \) for \( \lambda \) large enough thanks to (2.4). Moreover, the second equality at (3.18) stays the same up to a multiplicative constant.

- In view of the first update, we replace \( A_i \cap C \geq h_0 \) by \( A_i \cap C^{h_0,3h_0}(r_{2n}) \) in (3.16) and in the rest of the proof of the upper bound for \( \mathbb{P}(G_1) \).

Moreover, the deterministic cylinder \( C_0 \) constructed in the proof of the upper bound for \( \mathbb{P}(G_2) \) on page 22 is replaced by a cylinder included in \( C^{h_2,3h_2}(r_{2n}) \) and with radius \( \frac{r_{2n}}{2n+3} \), say.

We then obtain (3.17) and (3.20) and conclude as in the case \( \lambda = \infty \).

\[ \square \]

Proposition 3.3 is a general stabilization result for the score at one fixed point and this stabilization is lateral, meaning that the point process is intersected with a cylinder. Lemma 3.4 below is a complementary stabilization result in a cylinder and the stabilization there is in height, meaning that the point process is intersected with a horizontal strip. Combining Lemma 3.4 with Proposition 3.3, we can deduce a general stabilization result both in width and height. The stabilization in height is required to restrict the peeling to a cylinder bounded in height later on and use the continuous mapping theorem, see Lemma 4.2. This will ultimately imply in particular a convergence result for the mean of the functional \( \xi(\lambda) \), see Proposition 4.3. An extra refinement contained in Lemma 3.4 is that the stabilization in height is proved to be uniform for all the points inside a small cylinder. This will be needed for getting the stabilization in height of the \( k \)-face score, see Lemma 3.7.

Lemma 3.4. For all \( n \geq 1 \), there exist \( \lambda_0, c_1, c_2 > 0 \) such that for all \( \lambda \in [\lambda_0, \infty) \) and \( 1 \leq r < \pi \lambda^{\frac{1}{2n+1}} \), we have

\[
\mathbb{P} \left( \exists w \in \mathcal{P}(\lambda) \cap C^{\leq lr^2} \left( \frac{r}{2n+1} \right) : \xi_{n,0}(w, \mathcal{P}(\lambda) \cap C(r)) \neq \xi_{n,0}(w, \varnothing \cap C^{\leq lr^2}(r)) \right) \leq c_1 \exp(-c_2 r^{d+1})
\]

with \( l_n = \frac{1}{2n+1} \).

Proof. As in the previous proofs, we proceed in the case \( \lambda = \infty \) and explain at the end how to adapt the arguments in the case \( \lambda < \infty \). For fixed \( n \), we prove by induction on \( m \) that for all \( m \leq n \) there exists \( c_1, c_2 > 0 \) such that for all \( r \geq 1 \) we have

\[
\mathbb{P} \left( \exists w \in \mathcal{P} \cap C^{\leq lr^2} \left( \frac{r}{2m+1} \right) : \xi_{m,0}(w, \mathcal{P} \cap C(r)) \neq \xi_{m,0}(w, \varnothing \cap C^{\leq lr^2}(r)) \right) \leq c_1 \exp(-c_2 r^{d+1}).
\]

(3.21)

Lemma 3.4 is then derived from (3.21) by taking \( m = n \).

Proof of the base case \( m = 1 \) for \( \lambda = \infty \). Let \( w \in C^{\leq lr^2}(\frac{r}{2}) \) and assume that \( \xi_{1,0}(w, \mathcal{P} \cap C(r)) \neq \xi_{1,0}(w, \varnothing \cap C^{\leq lr^2}(r)) \).
Then there exists a downward paraboloid $\Pi^\downarrow(v_1, h_1)$, whose boundary contains $w$, that contains no point of $\mathcal{P} \cap C_{\leq l_n r^2}(r)$ and contains at least one point of $\mathcal{P} \cap C(r)$.

If $h_1 \leq l_n r^2$, we observe that thanks to $l_n = \frac{1}{2^{2n+7}}$ and the fact that $w \in C\left(\frac{r}{4}\right)$, we get for any $(v', h') \in \Pi^\downarrow(v_1, h_1)$,

\[
\|v'\| \leq \|v' - v_1\| + \|v_1\| \leq \sqrt{2h_1} + \|v - v_1\| + \|v\| \leq 2\sqrt{2h_1} + \frac{r}{4} \\
\leq 2\sqrt{2l_n r^2} + \frac{r}{4} \leq r.
\]

The last inequality in (3.22) implies that $\Pi^\downarrow(v_1, h_1)$ is contained in $C_{\leq l_n r^2}(r)$ which is excluded.

If $h_1 > l_n r^2$, we claim that the intersection between $\Pi^\uparrow(w)$ and the vertical plane containing $w$ and $(v_1, h_1)$ contains exactly two points at height equal to $l_n r^2$ and we call $(v_2, h_2)$ the one which is closer to $(v_1, h_1)$, see Fig. 7.

Thanks to Lemma 3.1, the paraboloid $\Pi^\uparrow(v_1, h_1)$ contains half of the down paraboloid with apex at the vertical projection of $(v_2, h_2)$ onto $\partial \Pi^\uparrow(v_1, h_1)$. Consequently, $\Pi^\downarrow(v_1, h_1)$ also contains $\Pi^\downarrow_+(v_2, h_2) \cap C_{\leq l_n r^2}(r)$ where $\Pi^\downarrow_+(v_2, h_2)$ denotes half of $\Pi^\downarrow(v_2, h_2)$. This latter set has volume $cr^{d+1}$ so we can show by using deterministic orthants as in the proof of Lemma 3.2 that

\[
\mathbb{P}(\mathcal{P} \cap \Pi^\downarrow_+(v_2, h_2) \cap C_{\leq l_n r^2}(r) = \emptyset) \leq \exp(-cr^{d+1}).
\]

Denoting by $D$ the set of points of $\partial \Pi^\uparrow(w)$ at height $l_n r^2$ and discretizing $D$, we obtain

\[
\mathbb{P}(\exists (v_2, h_2) \in D : \mathcal{P} \cap \Pi^\downarrow_+(v_2, h_2) \cap C_{\leq l_n r^2}(r) = \emptyset) \leq c_1 \exp(-c_2 r^{d+1}).
\]
Using Mecke’s formula we get
\[
\mathbb{P} \left( \exists w \in \mathcal{P}^{(\lambda)} \cap C_{\leq \ln r^2} \left( \frac{r}{4} \right) : \xi_{1,0}^{(\infty)}(w, \mathcal{P}^{(\lambda)} \cap C(r)) \neq \xi_{1,0}^{(\infty)}(w, \mathcal{P}^{(\lambda)} \cap C_{\leq \ln r^2}(r)) \right) \\
\leq c_1 \operatorname{Vol}_d \left( C_{\leq \ln r^2} \left( \frac{r}{4} \right) \right) \exp(-c_2 r^{d+1}) \leq c_1 \exp(-c_2 r^{d+1}).
\]
This proves the base case for $\lambda = \infty$.

**Proof of the induction step for $\lambda = \infty$.** Now for fixed $2 \leq m \leq n$ we assume that the result holds for any $p < m$ and we show that it remains true for $m$. Let $w \in C_{\leq \ln r^2} \left( \frac{r}{2^{m+1}} \right)$. We denote by $E_w$ the event
\[E_w := \{ \xi_{m,0}^{(\infty)}(w, \mathcal{P} \cap C(r)) \neq \xi_{m,0}^{(\infty)}(w, \mathcal{P} \cap C_{\leq \ln r^2}(r)) \}.
\]
When on $E_w$, we also assume that $\xi_{m,0}^{(\infty)}(w, \mathcal{P} \cap C_{\leq \ln r^2}(r)) = 1$, i.e. $\ell^{(\infty)}(w, \mathcal{P} \cap C_{\leq \ln r^2}(r)) = m$.

Indeed, the case $\xi_{m,0}^{(\infty)}(w, \mathcal{P} \cap C(r)) = 1$ can be treated in a similar way, see what we did when dealing with events $E_1$ and $E_2$ in the proof of Proposition 3.3. In particular, when $\ell^{(\infty)}(w, \mathcal{P} \cap C_{\leq \ln r^2}(r)) = m$, the depth $\ell^{(\infty)}(w, \mathcal{P} \cap C(r))$ is larger than $(m + 1)$ thanks to Lemma 2.6.

In other words, there exists a downward paraboloid $\Pi^+(v_1, h_1)$ whose boundary contains $w$ and that only contains points on a layer of order at most $(m - 1)$ for the peeling in $C_{\leq \ln r^2}(r)$ and at least one point denoted by $(v_3, h_3)$ such that
\[
\ell^{(\infty)}((v_3, h_3), \mathcal{P} \cap C(r)) \geq m \text{ and } \ell^{(\infty)}((v_3, h_3), \mathcal{P} \cap C_{\leq \ln r^2}(r)) \leq m - 1.
\]
(3.24)

If $h_1 \leq \ln r^2$, then for $(v', h') \in \Pi^+(v_1, h_1)$, we obtain by the same method as in (3.22) that
\[
\|v'\| \leq 2\sqrt{2h_1} + \frac{r}{2^{m+1}} \leq 2\sqrt{2\ln r^2} + \frac{r}{2^{m+1}} \leq \frac{r}{2^{m+1}}.
\]
(3.25)

We notice that the last inequality in (3.25) still holds when $l_n$ is replaced by $\frac{1}{\sqrt{\ln n}}$, which means that our current calibration takes into account the case $\lambda < \infty$ which is discussed at the end of the proof. The estimate (3.25) shows that the paraboloid $\Pi^+(v_1, h_1)$ stays in $C_{\leq \ln r^2} \left( \frac{r}{2^{m+1}} \right)$. Consequently the point $(v_3, h_3)$ introduced above belongs to $C_{\leq \ln r^2} \left( \frac{r}{2^{m+1}} \right)$ and by (3.24), it satisfies $\xi_{p,0}^{(\infty)}((v_3, h_3), \mathcal{P} \cap C_{\leq \ln r^2}(r)) \neq \xi_{p,0}^{(\infty)}((v_3, h_3), \mathcal{P} \cap C(r))$ for $p = \ell^{(\infty)}((v_3, h_3), \mathcal{P} \cap C_{\leq \ln r^2}(r)) < m$. Using the induction hypothesis, this happens with probability smaller than $c_1 \exp(-c_2 r^{d+1})$.

If $h_1 > \ln r^2$ we proceed as in the case $m = 1$ by using the construction described in Fig. 7. Namely, we show that there exists half of a paraboloid whose apex is on $\partial \Pi^+(w)$ at height $\ln r^2$ and that only contains points on a layer of order at most $(m - 1)$ for the
peeling of $\mathcal{P} \cap C^{\leq lr^2}(r)$. Let us denote by $A$ this half-paraboloid. Thanks to (3.25), the set $A$ is included in $C\left(\frac{r}{2m}\right)$ which implies that

$$
\mathbb{P}\left(\mathcal{P} \cap A \cap C^{\leq lnr^2/2}\left(\frac{r}{2m}\right) = \emptyset\right) \leq \exp(-cr^d+1).
$$

(3.26)

If $\mathcal{P} \cap A \cap C^{\leq lnr^2/2}\left(\frac{r}{2m}\right) \neq \emptyset$, we choose $(v_4, h_4)$ in that set and two cases arise.

If $\ell^{(\infty)}((v_4, h_4), \mathcal{P} \cap C(r)) = \ell^{(\infty)}((v_4, h_4), \mathcal{P} \cap C^{\leq lnr^2}(r))$, then $\ell^{(\infty)}((v_4, h_4), \mathcal{P} \cap C(r)) \leq (m - 1)$ and $h_4 \geq lnr^2/2 = cr^2$. Using Lemma 3.2, this happens with probability smaller than $c_1 \exp(-c_2r^d+1)$.

If $\ell^{(\infty)}((v_4, h_4), \mathcal{P} \cap C(r)) \neq \ell^{(\infty)}((v_4, h_4), \mathcal{P} \cap C^{\leq lnr^2}(r))$, we can use the induction hypothesis and a union bound for $p < m$ to prove that this happens with probability smaller than $c_1 \exp(-c_2r^d+1)$.

To sum up, we have shown that for any $w \in C^{\leq lnr^2}\left(\frac{r}{2m}\right)$

$$
\mathbb{P}(E_w) \leq c_1 r^{(m-1)(d+1)} \exp(-c_2r^d+1).
$$

Using Mecke’s formula, we finally obtain

$$
\mathbb{P}\left(\exists w \in C^{\leq lnr^2}\left(\frac{r}{2m+1}\right) : \xi^{(\infty)}(w, \mathcal{P}^{(\lambda)} \cap C(r)) \neq \xi^{(\infty)}(w, \mathcal{P}^{(\lambda)} \cap C^{\leq lnr^2}(r))\right) \leq c_1 r^{m(d+1)} \exp(-c_2r^d+1).
$$

Case $\lambda < \infty$. We have to adapt the arguments where either the actual equation of a paraboloid or a lower bound of the intensity measure of $\mathcal{P}$ is used, namely (3.22), (3.23), (3.25) and (3.26). Thanks to (2.4), for $\lambda$ large enough, the series of estimates leading to (3.22) can be replaced by

$$
\|v’\| \leq \cdots \leq 4\sqrt{2}h_1 + \frac{r}{4} \leq 4\sqrt{2}lnr^2 + \frac{r}{4} \leq r.
$$

(3.27)

The adaptation of (3.25) is identical.

In order to show (3.23) for $\lambda < \infty$, we use (3.27) to show that $[\Pi^1]^{(\lambda)}(v_2, h_2)$ is included in $C(\xi)$ for $\lambda$ large enough. In particular, the set $[\Pi^1]^{(\lambda)}(v_2, h_2) \cap C^{\leq lnr^2}(r)$ is contained in $C^{<\lambda,\frac{2}{\pi+1}}/(\frac{1}{2}\lambda, \frac{1}{\pi+1}r)$ which is a domain where the intensity measure of $\mathcal{P}^{(\lambda)}$ is bounded from below. Consequently, (3.23) occurs for $\lambda < \infty$ as well. In the same way, the estimate (3.26) holds for $\lambda < \infty$ as well because $A \cap C^{\leq lnr^2/2}\left(\frac{r}{2m}\right)$ is included in $C^{<\lambda,\frac{2}{\pi+1}}/(\frac{1}{2}\lambda, \frac{1}{\pi+1}r)$.

3.3 Stabilization for k-faces

Henceforth, we fix $n \geq 1$ and $k \in \{0, \ldots, d-1\}$. We aim at proving Proposition 3.6 which states a stabilization result for the quantities $\xi^{(\lambda)}_{n,k}$ introduced at (2.11).
do so, we start with an intermediary lemma on the distribution tail of the height of the parabolic facets containing a fixed point from the \( n \)-th layer.

Let us recall the definition of the set \( \mathcal{F}_{n,d-1}^{(\lambda)}(w, Y) \) given on page 13. For any locally finite set \( Y \subset \mathbb{R}^{d-1} \times \mathbb{R}^+ \) and \( w = (v, h) \in \mathbb{R}^{d-1} \times \mathbb{R}^+ \), we introduce the maximal height of the facets from \( \mathcal{F}_{n,d-1}^{(\lambda)}(w, Y) \), i.e. \( H_n^{(\lambda)}(w, Y) = 0 \) if \( w \notin \partial \Phi_n(Y) \) and otherwise,

\[
H_n^{(\lambda)}(w, Y) = \sup\{h_1 > 0 : \exists v_1 \in \mathbb{R}^{d-1}, F \in \mathcal{F}_{n,d-1}^{(\lambda)}(w, Y) \text{ s.t. } F \subset \partial[\Pi_r^{(\lambda)}(v_1, h_1)]\}.
\]

(3.28)

**Lemma 3.5** For all \( n \geq 1 \) there exist \( \lambda_0, c_1, c_2 > 0 \) such that for all \( \lambda \in [\lambda_0, +\infty) \), \( h_0 \in (0, \frac{2}{\pi \lambda^{\frac{1}{2}}}) \), \( t > 0 \) and \( 1 \leq r < \pi \lambda^{\frac{1}{2}} \), we have

\[
\mathbb{P}(\exists s \geq r : H_n^{(\lambda)}((0, h_0), \mathcal{P}^{(\lambda)} \cap C(s)) \geq t) \leq c_1 \exp(-c_2 \sqrt{t}(r \wedge \sqrt{t})^d)
\]

and

\[
\mathbb{P}(H_n^{(\lambda)}((0, h_0), \mathcal{P}^{(\lambda)}) \geq t) \leq c_1 \exp(-c_2 t^{\frac{d+1}{2}}).
\]

(3.29) (3.30)

**Proof** We only prove (3.29) as the proof of (3.30) is almost identical.

**Case** \( \lambda = \infty \). For \( (v_1, h_1) \in \mathbb{R}^{d-1} \times \mathbb{R}^+ \), we introduce the events

\[
E_{(v_1,h_1)} = \{\exists s \geq r, F \in \mathcal{F}_{n,d-1}((0, h_0), \mathcal{P} \cap C(s)), F \subset \partial[\Pi_r^{(\lambda)}(v_1, h_1)]\}
\]

and

\[
E = E(t) := \bigcup_{(v_1,h_1) \in \Pi_r^{(\lambda)}(0, h_0), h_1 \geq t} E_{(v_1,h_1)}.
\]

It is enough to prove that

\[
\mathbb{P}(E) \leq c_1 \exp(-c_2 \sqrt{t}(r \wedge \sqrt{t})^d).
\]

(3.31)

In the same spirit as in the proof of Proposition 3.3, we consider two cases depending on the value of \( h_0 \). The left- (resp. right-) hand side of Fig. 6 reflects the first case \( h_0 \geq t/2 \) (resp. \( h_0 \leq t/2 \)).

**Case** \( h_0 \geq t/2 \). As in the proof of Lemma 3.2, we start by decomposing \( \Pi_r^{(\lambda)}(0, h_0) \) into \( 2^{d-1} \) deterministic subparts \( A_1, \ldots, A_{2^{d-1}} \) such that

\[
\text{Vol}_d(A_i \cap C^{h_0/2}((r \wedge \sqrt{t})/2^n)) = \frac{1}{2^{d-1}} \text{Vol}_d(\Pi_r^{(\lambda)}((0, h_0)) \cap C^{h_0/2}((r \wedge \sqrt{t})/2^n)) \geq c t (r \wedge \sqrt{t})^{d-1}.
\]

(3.32)

Let \( (v_1, h_1) \in \Pi_r^{(\lambda)}(0, h_0) \) such that \( h_1 \geq t \) and \( \partial \Pi_r^{(\lambda)}(v_1, h_1) \) contains a facet of \( \partial \Phi_n(\mathcal{P} \cap C(s)) \) going through \( (0, h_0) \) for some \( s \geq r \). By Lemma 3.1, \( \Pi_r^{(\lambda)}(v_1, h_1) \)
contains half of $\Pi^\downarrow(0, h_0)$, which implies that it contains a set $A_i \cap C^{\geq h_0/2}((r \land \sqrt{t})/2^n)$ for some $i$. Consequently,

$$
\mathbb{P}(E) = \mathbb{P}\left( \bigcup_{(v_1, h_1) \in \Pi^\downarrow(0, h_0), h_1 > t} E_{(v_1, h_1)} \right)
\leq \mathbb{P}\left( \bigcup_{s \geq r} \bigcup_{i = 1}^{2d-1} \{ \mathcal{P} \cap A_i \cap C^{\geq h_0/2}((r \land \sqrt{t})/2^n) \subset [\Phi_n(\mathcal{P} \cap C(s))]^c \} \right)
\leq \mathbb{P}\left( \bigcup_{i = 1}^{2d-1} \{ \mathcal{P} \cap A_i \cap C^{\geq h_0/2}((r \land \sqrt{t})/2^n) \subset [\Phi_n(\mathcal{P} \cap C(r))]^c \} \right)
\leq 2^{d-1}\mathbb{P}(\mathcal{P} \cap A_1 \cap C^{\geq h_0/2}((r \land \sqrt{t})/2^n) \subset [\Phi_n(\mathcal{P} \cap C(r))]^c).
$$

(3.33)

where the inclusion $\Phi_n(\mathcal{P} \cap C(r)) \subset \Phi_n(\mathcal{P} \cap C(s))$ is due to Lemma 2.6. By (3.32), $\mathcal{P}$ does not meet $A_1 \cap C^{\geq h_0/2}((r \land \sqrt{t})/2^n)$ with probability smaller than $\exp(-ct(r \land \sqrt{t})^{d-1})$. Otherwise it contains a point $(v_3, h_3)$ with $h_3 \geq h_0/2 \geq t/4$ and such that $\ell^{(\infty)}((v_3, h_3), \mathcal{P} \cap C(r)) \leq (n - 1)$. Using Lemma 3.2, we obtain that

$$
\mathbb{P}(\mathcal{P} \cap A_1 \cap C^{\geq h_0/2}((r \land \sqrt{t})/2^n) \subset \Phi_n^c(\mathcal{P} \cap C(r))) \leq c_1 \exp(-c_2 t(r \land \sqrt{t})^{d-1}),
$$

which implies (3.31) thanks to (3.33) and the inequality $t(r \land \sqrt{t})^{d-1} \geq \sqrt{t}(r \land \sqrt{t})^d$.

Case $h_0 \leq t/2$. Let $(v_1, h_1) \in \partial \Pi^\downarrow(0, h_0)$ such that $h_1 \geq t$ and $\partial \Pi^\downarrow(v_1, h_1)$ contains a facet of $\partial \Phi_n(\mathcal{P} \cap C(s))$ going through $(0, h_0)$ for some $s \geq r$. For $u > 0$, the height of the highest point of intersection between $\Pi^\downarrow(v_1, h_1)$ and $C(u/2^{n+1})$ in the vertical plane containing $(v_1, h_1)$ and the origin is

$$
h_2 := h_0 + \sqrt{2(h_1 - h_0) \frac{u}{2n+1} - \frac{u^2}{2^{2n+3}}}. 
$$

(3.34)

We take $u = \sqrt{2(h_1 - h_0) \land r}$ and fit a cylinder $C_0$ of radius $\frac{u}{2n+1}$ between height $h_2/2$ and $h_2$ in $C(\frac{u}{2n+1}) \cap \Pi^\downarrow(v_1, h_1)$, see the right-hand side of Fig. 6 with $r$ replaced by $u$.

Either the point process $\mathcal{P}$ does not meet the cylinder $C_0$ which happens with probability $\exp(-ch_2u^{d-1})$ or it contains a point $(v_3, h_3)$ with $h_3 \geq h_2/2$ and such that

$$
\ell^{(\infty)}((v_3, h_3), \mathcal{P} \cap C(r)) \leq \ell^{(\infty)}((v_3, h_3), \mathcal{P} \cap C(s)) \leq (n - 1).
$$

Using Lemma 3.2, this happens with probability smaller than $c_1 \exp(-c_2 h_2(u \land \sqrt{h_2})^{d-1})$. Consequently, we get

$$
\mathbb{P}(E_{(v_1, h_1)}) \leq c_1 u^{d-1} \exp\left(-c_2 h_2(u \land \sqrt{h_2})^{d-1}\right).
$$

(3.35)
It remains to make explicit the right-hand side of (3.35) in the two cases \( u = \sqrt{2(h_1 - h_0)} \) and \( u = r \).

When \( u = \sqrt{2(h_1 - h_0)} \leq r \), we deduce from (3.34) and the fact that \( h_1 \geq t \) that

\[
h_2 = h_0 + \frac{h_1 - h_0}{2^n} - \frac{h_1 - h_0}{2^{2(n+1)}} \geq c(h_1 - h_0) \geq c't.
\] (3.36)

Combining (3.35) with (3.36), we obtain

\[
\mathbb{P}(E_{(v_1,h_1)}) \leq c_1 \exp(-c_2(h_1 - h_0)\sqrt{r}^{d-1}).
\] (3.37)

When \( u = r \leq \sqrt{2(h_1 - h_0)} \), we obtain in the same way

\[
\mathbb{P}(E_{(v_1,h_1)}) \leq c_1 \exp(-c_2(h_1 - h_0)r^d).
\] (3.38)

Discretizing and integrating the right-hand sides of (3.37) and (3.38) over the set \( \{(v_1,h_1) \in \Pi^+(0, h_0) : h_1 \geq t \} \), we deduce (3.31) when \( h_0 \leq t/2 \).

This completes the proof of (3.29) in the case \( \lambda = \infty \).

Case \( \lambda < \infty \). In the case \( h_0 \geq t/2 \), we need to replace \( A_i \cap C^{h_0/2}/((r \wedge \sqrt{r})/2^n) \) with \( A_i \cap C^{(h_0/2, 3h_2/2)}((r \wedge \sqrt{r})/2^n) \) which is included in \( C^{\left\lceil \frac{\lambda}{2} \frac{1}{2^n} \right\rceil}((r \wedge \sqrt{r})/2^n) \) so that we can lower bound by a constant the density of the intensity measure of \( \mathcal{P}(\lambda) \) when on that particular set. We adapt the case \( h_0 \leq t/2 \) in the exact same way as in the proof of Proposition 3.3 by replacing the equality (3.34) by an inequality up to a multiplicative constant and reducing the cylinder \( C_0 \) so that it is included in \( C^{(h_2/2, \lambda h_2/2)}((r \wedge \sqrt{r})/2^n) \), which makes it possible to lower bound by a constant the density of the intensity measure of \( \mathcal{P}(\lambda) \) on \( C_0 \).

**Proposition 3.6** For any \( n \geq 1 \) there exists \( \lambda_0, c_1, c_2 > 0 \) such that for any \( h_0 > 0, \lambda \in [\lambda_0, +\infty] \) and \( 1 \leq r < \frac{\lambda}{2^n} \), we have

\[
\mathbb{P}\left(R_{n,k}^{(\lambda)}(0, h_0) \geq r \right) \leq c_1 \exp\left(-c_2 r^{d+1}\right).
\]

**Proof** Let us assume that \( R_{n,k}^{(\lambda)}(0, h_0) > r \).

First, we can also assume that \( R_{n,0}^{(\lambda)}(0, h_0) < r \) since the complement occurs with probability smaller than \( c_1 \exp\left(-c_2 r^{d+1}\right) \) by Proposition 3.3. In particular we have \( \xi_{n,0}^{(\lambda)}((0, h_0), \mathcal{P}(\lambda)) = \xi_{n,0}^{(\lambda)}((0, h_0), \mathcal{P}(\lambda) \cap C(s)) \) for every \( s \geq r \). We can also assume that both are different from 0, or equivalently that \( (0, h_0) \) is on the n-th layer for both peelings because otherwise we would have \( R_{n,k}^{(\lambda)}(0, h_0) \leq r \).

Thanks to Lemma 3.5, we have \( \min(H_n((0, h_0), \mathcal{P}(\lambda)), \max_{s \geq r} H_n((0, h_0), \mathcal{P}(\lambda) \cap C(s))) > r^2/32 \) with probability smaller than \( c_1 \exp\left(-c_2 r^{d+1}\right) \). Consequently, we can assume that for any \( s \in [r, \infty], H_n((0, h_0), \mathcal{P}(\lambda) \cap C(s)) \leq r^2/32 \).
Let
\[ \mathcal{U} = \mathcal{U}(h_0, r^2/32) := \bigcup_{(v_1, h_1) \in \partial [\Pi^1(\lambda)](0, h_0), h_1 \leq r^2/32} \Pi^1(v_1, h_1). \] (3.39)

When \( \lambda = \infty \), a point \((v, h) \in \mathcal{U}\) verifies \( \|v\| \leq \sqrt{2(r^2/32 - h_0)} + \sqrt{2r^2/32} \leq 2\sqrt{2r^2/32} \leq r/2\). By (2.4), this implies that for \( \lambda \) large enough, a point \((v, h) \in \mathcal{U}\) satisfies \( \|v\| \leq \frac{3}{4} r \).

The set \( \mathcal{U} \) is designed to include all points of \( \mathcal{P}^{(\lambda)} \) which lie on a common \( k \)-face of \( \partial \Phi_n(\mathcal{P}^{(\lambda)} \cap C(s)) \) with \((0, h_0)\) for every \( s \in [r, \infty] \). We assert that
\[ \{ R^{(\lambda)}_{n,k}((0, h_0), \mathcal{P}^{(\lambda)}) \geq r \} \subset \{ \exists w \in \mathcal{P}^{(\lambda)} \cap \mathcal{U} : R^{(\lambda)}_{n,0}(w, \mathcal{P}^{(\lambda)}) \geq r/4 \}. \] (3.40)

Indeed, if every point \( w \in \mathcal{P}^{(\lambda)} \cap \mathcal{U} \) verifies \( R^{(\lambda)}_{n,0}(w, \mathcal{P}^{(\lambda)}) \leq r/4 \), then the status of these points with respect to the \( n \)-th layer is the same for both \( \mathcal{P}^{(\lambda)} \) and \( \mathcal{P}^{(\lambda)} \cap C(s) \), for any \( s \geq r \). Consequently, the \( k \)-faces of the \( n \)-th layer containing \((0, h_0)\) are the same for the peeling of any \( \mathcal{P}^{(\lambda)} \cap C(s), s \geq r \), which implies that \( R^{(\lambda)}_{n,k}((0, h_0), \mathcal{P}^{(\lambda)}) \leq r \). Using consecutively (3.40), Mecke’s formula and the fact that the density of the intensity measure of \( \mathcal{P}^{(\lambda)} \) is upper bounded by 1, we have
\[
\mathbb{P}(R^{(\lambda)}_{n,k}(0, h_0)) \geq r \leq \mathbb{E} \left[ \sum_{x \in \mathcal{U} \cap \mathcal{P}^{(\lambda)}} 1_{R^{(\lambda)}_{n,0}(x) \geq r/4} \right] \\
\leq \int_{\mathcal{U}} \mathbb{P}(R^{(\lambda)}_{n,0}(x) \geq r/4)dx \\
\leq \text{Vol}_d(\mathcal{U}) c_1 \exp(-c_2 r^{d+1})dx. \\
\leq c_1 \exp(-c_2 r^{d+1}).
\]

This yields the result. \( \square \)

The final result of this section is a slight analogue of Proposition 3.6 for the stabilization in height, i.e. we prove that with high probability the calculation of the score of \((0, h_0)\) inside the cylinder \( C(r) \) does not depend on the points of the point process which are higher than \( r^2 \) up to a multiplicative constant. The statement of that result uses the following notation: for \( w = (v, h) \in W_k, r, h > 0, n \geq 1 \) and \( k \in \{0, \ldots, d - 1\} \), we denote by \( \xi^{(\lambda)}_{n,k,[r,h]}(w) \) the quantity
\[ \xi^{(\lambda)}_{n,k,[r,h]}(w, \mathcal{P}^{(\lambda)}) = \xi^{(\lambda)}_{n,k}(w, \mathcal{P}^{(\lambda)} \cap C_v \leq h(r)). \]

Let us also recall the notation \( \xi^{(\lambda)}_{n,k,[r]}(w, \mathcal{P}^{(\lambda)}) \) introduced at (3.4).
Lemma 3.7 For all $n \geq 1$ and there exists $\lambda_0, c > 0$ such that for all $h_0 > 0$, $\lambda \in [\lambda_0, +\infty]$ and $1 \leq r < \pi \lambda^{\frac{1}{d+1}}$, we have

$$
P \left( \xi_{n,k,[r]}^{(\lambda)}((0, h_0), \mathcal{P}^{(\lambda)}) \neq \xi_{n,k,[r,l_n r^2]}^{(\lambda)}((0, h_0), \mathcal{P}^{(\lambda)}) \right) \leq c_1 \exp(-c_2 r^{d+1})$$

with $l_n = \frac{1}{2^{d+1}r}$.

Proof We denote by $A$ the event $\{H_n((0, h_0), \mathcal{P}^{(\lambda)} \cap C(r) > l_n r^2)\}$. Using Lemma 3.5 with the choice $r$ for $t$ and $l_n r^2$ for $r$, we get

$$
P(A) \leq c_1 \exp(-c_2 r^{d+1}). \quad (3.41)$$

On the event $A^c$, every paraboloid containing a facet going through $(0, h_0)$ of $\partial \Phi_n(\mathcal{P}^{(\lambda)} \cap C(r))$ has height smaller than $l_n r^2$. This implies that every point that shares a facet of $\partial \Phi_n(\mathcal{P}^{(\lambda)} \cap C(r))$ with $(0, h_0)$ is on the boundary of such a paraboloid and is consequently included in $C^{\leq l_n r^2} \left( \frac{r}{2^{d+1}} \right)$ by the same method as in (3.23). Using Lemma 3.4, we obtain that with probability larger than $1 - c_1 \exp(-c_2 r^{d+1})$, any $w \in C^{\leq l_n r^2} \left( \frac{r}{2^{d+1}} \right)$ verifies $\xi_{n,0,[r]}^{(\lambda)}(w, \mathcal{P}^{(\lambda)}) = \xi_{n,0,[r,l_n r^2]}^{(\lambda)}(w, \mathcal{P}^{(\lambda)})$.

Thus we deduce that with probability larger than $1 - c_1 \exp(-c_2 r^{d+1})$, the $k$–faces containing $w$ of $\partial \Phi_n(\mathcal{P}^{(\lambda)} \cap C(r))$ coincide with those of $\partial \Phi_n(\mathcal{P}^{(\lambda)} \cap C^{\leq l_n r^2}(r))$. In other terms we have proved that

$$
P \left( \left\{ \xi_{n,k,[r]}^{(\lambda)}((0, h_0), \mathcal{P}^{(\lambda)}) \neq \xi_{n,k,[r,l_n r^2]}^{(\lambda)}((0, h_0), \mathcal{P}^{(\lambda)}) \right\} \cap A^c \right) \leq c_1 \exp(-c_2 r^{d+1}). \quad (3.42)$$

Combining (3.41) and (3.42), we obtain the result. $\square$

4 $L^p$ bounds and pointwise convergences

In this section, we prove intermediary results on the functionals $\xi_{n,k}^{(\lambda)}$ and their variations which depend on the stabilization properties of Sect. 3 and pave the way to the proofs of Theorems 2.10 and 2.11. More precisely, Lemma 4.1 states some moment bounds, Lemma 4.2 and Proposition 4.3 show in two steps the convergence of the expectation of $\xi_{n,k}^{(\lambda)}$ to the expectation of $\xi_{n,k}^{(\infty)}$. We then deduce similar results for covariances of scores in Proposition 4.4 and Lemma 4.5.

Lemma 4.1 For any $p \in [1, +\infty)$, there exist constants $\lambda_0, c > 0$ such that for any $(v, h) \in \mathbb{R}^{d-1} \times \mathbb{R}_+, \lambda \in [\lambda_0, \infty]$ and $1 \leq r < \pi \lambda^{\frac{1}{d+1}}$

$$
\mathbb{E} \left[ \xi_{n,k}^{(\lambda)}((v, h), \mathcal{P}^{(\lambda)})^p \right] \leq c_1 h^{pk} \exp(-c_2 h^{\frac{d+1}{2}}) \quad (4.1)
$$

$$
\mathbb{E} \left[ \xi_{n,k,[r]}^{(\lambda)}((v, h), \mathcal{P}^{(\lambda)})^p \right] \leq cr^{pk(d-1)+1}(h \lor r^2)^{pk} \quad (4.2)
$$
\[ \mathbb{E} \left[ \xi_{n, k, [r, l n r^2]}^{(\lambda)}((v, h), \mathcal{P}^{(\lambda)})^p \right] \leq c r^{p k(d+1)+1}. \quad (4.3) \]

with \( l_n = \frac{1}{2d\pi r}. \)

**Proof** The method is almost identical to [15, Lemma 4.4]. For the sake of completeness and because the variants at (4.2) and (4.3) are new in comparison to [15], we provide an example the proof of (4.2).

We assert that \( \xi_{n, k, [r]}^{(\lambda)}((v, h), \mathcal{P}^{(\lambda)}) \leq \xi_{n, k, [r]}^{(\lambda)}((0, h), \mathcal{P}^{(\lambda)}) \) because of the rotation-invariance of the initial model in the unit ball.

We introduce the variables \( H := H_n^{(\lambda)}((0, h), \mathcal{P}^{(\lambda)} \cap C(r))) \) as defined at (3.28) and \( R \) as the smallest \( s > 0 \) such that \( C(s) \) contains \( \bigcup_{(v_1, h_1) \in \mathcal{P}^{(\lambda)} \cap \mathcal{P}(h, H)} C_{v_1} \left( R_n^{(\lambda)}(v_1, h_1) \right) \) where \( \mathcal{P}(h, \cdot) \) has been introduced at (3.39).

We assert that the proof of Proposition 3.6 implies that

\[ \mathbb{P}(R \geq r) \leq c_1 e^{-c_2 r^{d+1}}. \quad (4.4) \]

In particular, only the points in \( C^{\leq H}(R) \) can be part of a potential facet containing \((0, h)\) on \( \partial \Phi_n^{(\lambda)}(\mathcal{P}^{(\lambda)}) \). This implies that

\[ \mathbb{E}[N^{pk}] \leq c r^{p k(d+1)+1} (h \lor r^2)^{pk}. \quad (4.5) \]

We decompose the expectation in the following way:

\[
\begin{align*}
\mathbb{E}[N^{pk}] = & \sum_{i=1}^{[r]} \sum_{j=[h]+1}^{\infty} \mathbb{E}[N^{pk} \mathbbm{1}_{(i-1) \leq R \leq i} \mathbbm{1}_{(j-1) \leq H \leq j}] \\
\leq & \sum_{i=1}^{[r]} \sum_{j=[h]+1}^{\infty} \mathbb{E}[\text{card}(C^{\leq j}(i) \cap \mathcal{P}^{(\lambda)})^{pk} \mathbbm{1}_{(i-1) \leq R \leq i} \mathbbm{1}_{(j-1) \leq H \leq j}] \\
\leq & \sum_{i=1}^{[r]} \sum_{j=[h]+1}^{\infty} \mathbb{E}[\text{card}(C^{\leq j}(i) \cap \mathcal{P}^{(\lambda)})^{3pk} 1^{1/3} \mathbb{P}(R \geq i - 1) 1^{1/3} \mathbb{P}(H \geq j - 1) 1^{1/3}]
\end{align*}
\]

where the last line is a consequence of Hölder’s inequality. For any \( i, j \geq 0 \), we observe that \( C^{\leq j}(i) \) has volume \( c i^{d-1} j \) and thanks to (2.1), the \( d \mathcal{P}^{(\lambda)} \)-measure of \( C^{\leq j}(i) \) is bounded by its volume. Consequently, the variable \( \text{card}(\mathcal{P} \cap C^{\leq j}(i)) \) is stochastically dominated by a Poisson variable \( \text{Po}(c i^{d-1} j) \). Combining this fact, the moment bound \( \mathbb{E}[\text{Po}(\lambda)^r] \leq c \lambda^r \) for any \( r \geq 1 \) and (4.6), we obtain

\[ \mathbb{E}[N^{pk}] \leq c r^{p k(d+1)+1} (h \lor r^2)^{pk}. \]
\[
\mathbb{E}[N_{pk}] \leq \sum_{i=1}^{[r]} \sum_{j=[h]+1}^{\infty} c_i p^{k(d-1)} j^{pk-1} \mathbb{P}(R \geq (i-1))^{1/3} \mathbb{P}(H \geq (j-1)^{1/3}.
\]

Let us assume that \( h \leq r^2 \). We can now use Lemma 3.5 and (4.4) to get
\[
\mathbb{E}[N_{pk}] \leq \sum_{i=1}^{[r]} c_i p^{k(d-1)} e^{-c_2 d^{1/2}} \left( \sum_{j=[h]+1}^{[r^2]} j^{pk-1} e^{-c_3 j^{d^{1/2}}} + \sum_{j=[r^2]+1}^{\infty} j^{pk-1} e^{-c_4 \sqrt{jr^d}} \right)
\leq c_1 r^{pk(d-1)+1} r^{pk} \left( e^{-c_2 h^{d^{1/2}}} + e^{-c_3 r^{d^{1/2}}} \right).
\]

This shows (4.5) and consequently (4.2). We proceed in the same way when \( h \geq r^2 \).

\[ \square \]

The next lemma is a first step towards the convergence of the expectation of \( \xi_{n,k} \) stated in Proposition 4.3. It relies on the application of the continuous mapping theorem to the intersection of the point process \( \mathcal{P}(\lambda) \) with the compact set \( C_{\leq l_n r^2}(r) \).

**Lemma 4.2** There exists \( c > 0 \) such that for all \( h_0 \geq 0 \) and \( r \geq 1 \) we have
\[
\lim_{\lambda \to +\infty} \mathbb{E}[\xi_{n,k,(r)}((0, h_0), \mathcal{P}(\lambda))] - \mathbb{E}[\xi_{n,k,(r)}((0, h_0), \mathcal{P})] \leq c_1 r^{k(d-1)+1/2} (h_0 + r^2)^k e^{-c_2 r^{d^{1/2}}}.
\]

**Proof** For sake of simplicity, we use the following abbreviations:
\[
\xi_{n,k,(r)} := \xi_{n,k,(r)}((0, h_0), \mathcal{P}(\lambda)) \quad \text{and} \quad \xi_{n,k,(r)} := \xi_{n,k,(r)}((0, h_0), \mathcal{P}).
\]
Recalling \( l_n = \frac{1}{2^{n+7}} \), we use similar notations \( \xi_{n,k,(r,l_n r^2)}^{(\lambda)} \) and \( \xi_{n,k,(r,l_n r^2)}^{(\infty)} \) and obtain
\[
\mathbb{E}[\xi_{n,k,(r)}] - \mathbb{E}[\xi_{n,k,(r)}] = \left| \mathbb{E}[\xi_{n,k,(r),(l_n r^2)}] - \mathbb{E}[\xi_{n,k,(r),(l_n r^2)}] \right|
\leq \left| \mathbb{E}[\xi_{n,k,(r)}] - \mathbb{E}[\xi_{n,k,(r),(l_n r^2)}] \right| + \left| \mathbb{E}[\xi_{n,k,(r),(l_n r^2)}] - \mathbb{E}[\xi_{n,k,(r),(l_n r^2)}] \right| + \left| \mathbb{E}[\xi_{n,k,(r),(l_n r^2)}] - \mathbb{E}[\xi_{n,k,(r),(l_n r^2)}] \right|.
\]

We start by bounding the first term in the rhs of (4.7). Using the Cauchy-Schwarz inequality, we get
\[
\left| \mathbb{E}[\xi_{n,k,(r)}] - \mathbb{E}[\xi_{n,k,(r),(l_n r^2)}] \right| \leq \mathbb{E}[\mathbf{1}_{\{\xi_{n,k,(r)} \neq \xi_{n,k,(r),(l_n r^2)}\}}] \leq \mathbb{E}[\mathbf{1}_{\{\xi_{n,k,(r)} \neq \xi_{n,k,(r),(l_n r^2)}\}}]^{1/2} \mathbb{P}(\xi_{n,k,(r)} \neq \xi_{n,k,(r),(l_n r^2)})^{1/2}.
\]

Combining Lemma 3.7 and Lemma 4.1, we obtain for \( \lambda \) large enough
\[
\mathbb{E}[\xi_{n,k,(r)}] - \mathbb{E}[\xi_{n,k,(r),(l_n r^2)}] \leq c_1 r^{k(d-1)+1/2} (h_0 + r^2)^k \exp(-c_2 r^{d^{1/2}}). \quad (4.8)
\]
In the same way, we bound the third term in the rhs of (4.7) to get
\[
\left| \mathbb{E}[\xi^{(\infty)}_{n,k,[r,l_n r^2]} - \xi^{(\infty)}_{n,k,[r,l_n r^2]}] \right| \leq c_1 r^{k(d-1)+1/2} (h_0 \vee r^2)^k \exp(-c_2 r^{d+1}). \tag{4.9}
\]
Let us now prove that
\[
\lim_{\lambda \to +\infty} \mathbb{E}[\xi^{(\lambda)}_{n,k,[r,l_n r^2]}] = \mathbb{E}[\xi^{(\infty)}_{n,k,[r,l_n r^2]}]. \tag{4.10}
\]
To do so, we first prove the convergence in distribution of \(\xi^{(\lambda)}_{n,k,[r,l_n r^2]}\) to \(\xi^{(\infty)}_{n,k,[r,l_n r^2]}\).

We denote by \(\mathcal{X}(r, l_n r^2)\) the set of finite points sets in \(C^{l_n r^2}(r)\) and we endow it with the discrete topology. A sequence of point sets \((\eta_i)\) of \(\mathcal{X}(r, l_n r^2)\) converges to a point \(\eta\) if \(\eta_i = \eta\) for all \(i \geq i_0\) for some \(i_0 \in \mathbb{N}\).

We define for all \(w \in W_\lambda\) and \(\eta \in \mathcal{X}(r, l_n r^2)\)
\[g_{n,\lambda}(w, \eta) := \xi^{(\lambda)}_{n,k,[r,l_n r^2]}(w, \eta).\]

Considering that \(\mathcal{P}^{(\lambda)} \to \mathcal{P}\) in distribution in \(C^{l_n r^2}(r)\) by Lemma 2.1, we intend to show the convergence in distribution \(g_{n,\lambda}(w_0, \mathcal{P}^{(\lambda)}) \to g_{n,\infty}(w_0, \mathcal{P})\) by using [9, Theorem 5.5, p. 34]. To do so, we observe that since \(\mathcal{P}\) is in general position with probability 1, it is enough to prove that for any \(\eta \in \mathcal{X}(r, l)\) in general position, \(g_{n,\lambda}(w_0, \eta) = g_{n,\infty}(w_0, \eta)\) for all \(\lambda\) large enough.

Let \(\eta \in \mathcal{X}(r, l_n r^2)\) be in general position. We explain here why for each point \(w_1\) of \(\eta\), the number of the layer containing \(w_1\) and the local structure of that layer around \(w_1\) are fixed for \(\lambda\) large enough. We start by considering an extreme point \(w_1\) for the parabolic hull peeling of \(\eta\). We choose a \((d - 1)\)-dimensional parabolic face containing \(w_1\) which is generated by the extreme points \(w_1, w_2, \ldots, w_d\) and we also denote by \(\Pi^\perp(v, h)\) the downward paraboloid containing that face on its boundary.

For \(\varepsilon > 0\) small enough, the intersection of \(\Pi^\perp(v, h + \varepsilon)\) with \(\eta\) is \(\{w_1, \ldots, w_d\}\). Since the quasi-paraboloids converge to the real paraboloids as \(\lambda\) goes to infinity, for \(\lambda\) large enough the quasi-paraboloid with \(w_1, \ldots, w_d\) on its boundary is contained in \(\Pi^\perp(v, h + \varepsilon)\) and does not contain any point of \(\eta\) in its interior. This means that for \(\lambda\) large enough, \(w_1\) is extreme and the facets containing it are generated by the same points. Applying this to every extreme point, we deduce that the first layer is stable for \(\lambda\) large enough. By induction on the number of the layer, we prove similarly that the subsequent layers of the quasi-parabolic hull peeling of \(\eta\) are stable for \(\lambda\) large enough.

This means that \(g_{n,\lambda}(w_0, \eta) = g_{n,\infty}(w_0, \eta)\) for all \(\lambda\) large enough and as a consequence completes the proof of the convergence in distribution of \(\xi^{(\lambda)}_{n,k,[r,l_n r^2]}(w_0, \mathcal{P}^{(\lambda)})\) to \(\xi^{(\infty)}_{n,k,[r,l_n r^2]}(w_0, \mathcal{P})\). This extends to (4.10) by [9, Theorem 5.4] since the considered sequence is bounded in \(L^p\) with \(p > 1\) thanks to Lemma 4.1.

Inserting the results (4.8), (4.9) and (4.10) into (4.7), we deduce Lemma 4.2. □

We are now ready to state the required convergence in expectation in Proposition 4.3 below.
Proposition 4.3  For any $n \geq 1$ and all $h_0 > 0$ we have

$$\lim_{\lambda \to +\infty} \mathbb{E} \left[ \xi_{n,k}^{(\lambda)}((0,h_0),P^{(\lambda)}) \right] = \mathbb{E} \left[ \xi_{n,k}^{(\infty)}((0,h_0),P) \right].$$

Proof  With the same notation as in the proof of Lemma 4.2, we get from the triangle inequality that

$$\left| \mathbb{E}[\xi_{n,k}] - \mathbb{E}[\xi_{n,k}^{(\infty)}] \right| \leq \left| \mathbb{E}[\xi_{n,k}] - \mathbb{E}[\xi_{n,k,[r]}] \right| + \left| \mathbb{E}[\xi_{n,k,[r]}] - \mathbb{E}[\xi_{n,k}^{(\infty)}] \right| + \left| \mathbb{E}[\xi_{n,k}^{(\infty)}] - \mathbb{E}[\xi_{n,k}^{(\lambda)}] \right|.$$  \hspace{1cm} (4.11)

Using the same method as in the proof of (4.8), we obtain thanks to Proposition 3.6 and Lemma 4.1 that for $r$ large enough,

$$\max(|\mathbb{E}[\xi_{n,k}] - \mathbb{E}[\xi_{n,k,[r]}]|, |\mathbb{E}[\xi_{n,k}^{(\infty)}] - \mathbb{E}[\xi_{n,k}^{(\lambda)}]|) \leq r^{(d-1)/2} + 2k \epsilon^{-cr} d^{2}.$$  \hspace{1cm} (4.12)

Inserting (4.12) and the result of Lemma 4.2 into (4.11), we obtain that for any $\epsilon > 0$, there exists $r$ large enough such that $\lim_{\lambda \to +\infty} \left| \mathbb{E}[\xi_{n,k}] - \mathbb{E}[\xi_{n,k}^{(\lambda)}] \right| \leq \epsilon$. This completes the proof of Proposition 4.3. $\square$

In view of the required variance estimates, we now aim at extending Proposition 4.3 when the expectation of a score is replaced by the covariance of two scores $\xi_{n,k}^{(\lambda)}((0,h_0),P^{(\lambda)})$ and $\xi_{n,k}^{(\lambda)}((v_1,h_1),P^{(\lambda)})$ at two points $(0,h_0)$ and $(v_1,h_1)$ belonging to $W_{\lambda}$. To do so, we study the two-point correlation function defined at (2.13).

Proposition 4.4  For all $h_0 \geq 0$ and $(v_1,h_1) \in \mathbb{R}^{d-1} \times \mathbb{R}_+$ we have

$$\lim_{\lambda \to +\infty} c_{n,k}^{(\lambda)}((0,h_0),(v_1,h_1)) = c_{n,k}^{(\infty)}((0,h_0),(v_1,h_1)).$$

Proof  For sake of simplicity, let us use the following reduced notation for $\lambda \in [\lambda_0, \infty)$:

$$\xi_{n,k}^{(\lambda)}(0) := \xi_{n,k}^{(\lambda)}((0,h_0),P^{(\lambda)} \cup \{(v_1,h_1)\}), \xi_{n,k}^{(\lambda)}(1) := \xi_{n,k}^{(\lambda)}((v_1,h_1),P \cup \{(0,h_0)\}).$$  \hspace{1cm} (4.13)

By Proposition 4.3, we get

$$\lim_{\lambda \to +\infty} \mathbb{E} \left[ \xi_{n,k}^{(\lambda)}((0,h_0),P^{(\lambda)}) \right] \mathbb{E} \left[ \xi_{n,k}^{(\lambda)}((v_1,h_1),P^{(\lambda)}) \right] = \mathbb{E} \left[ \xi_{n,k}^{(\infty)}((0,h_0),P) \right] \mathbb{E} \left[ \xi_{n,k}^{(\infty)}((v_1,h_1),P) \right]$$

so we only need to prove

$$\lim_{\lambda \to +\infty} \mathbb{E} \left[ \xi_{n,k}^{(\lambda)}(0) \xi_{n,k}^{(\lambda)}(1) \right] = \mathbb{E} \left[ \xi_{n,k}^{(\infty)}(0) \xi_{n,k}^{(\infty)}(1) \right].$$  \hspace{1cm} (4.14)
Let us fix $\varepsilon > 0$. We can show that for $r$ large enough
\[
\lim_{\lambda \to \infty} \left| \mathbb{E} \left[ \xi(\lambda) (0) \xi(\lambda) (1) \right] - \mathbb{E} \left[ \xi(\lambda) (0) \xi(\lambda) (1) \right] \right| \leq \varepsilon, \quad (4.15)
\]
\[
\lim_{\lambda \to \infty} \left| \mathbb{E} \left[ \xi(\lambda) ([0,r]) \xi(\lambda) ([0,r]) \right] - \mathbb{E} \left[ \xi(\lambda) ([0,r]) \xi(\lambda) ([0,r]) \right] \right| \leq \varepsilon, \quad (4.16)
\]
\[
\lim_{\lambda \to \infty} \left| \mathbb{E} \left[ \xi(\lambda) ([0,r]) \xi(\lambda) ([0,r]) \right] - \mathbb{E} \left[ \xi(\lambda) ([0,r]) \xi(\lambda) ([0,r]) \right] \right| = 0, \quad (4.17)
\]
\[
\left| \mathbb{E} \left[ \xi(\lambda) (0) \xi(\lambda) (0) \right] - \mathbb{E} \left[ \xi(\lambda) (0) \xi(\lambda) (0) \right] \right| \leq \varepsilon, \quad (4.18)
\]
\[
\left| \mathbb{E} \left[ \xi(\lambda) (0) \xi(\lambda) (0) \right] - \mathbb{E} \left[ \xi(\lambda) (0) \xi(\lambda) (0) \right] \right| \leq \varepsilon \quad (4.19)
\]
where we have used the reduced notation for $\xi^{(\lambda)}_{n,k,r}$ and $\xi^{(\lambda)}_{n,k,[0,r]}$ and their counterparts in the limit model similar to the one introduced at (4.13). These five assertions imply (4.14) so it is enough to show each of them. We claim that (4.15), (4.16), (4.18) and (4.19) are obtained by similar methods. Consequently we omit the proofs of (4.16), (4.18) and (4.19) and concentrate on getting (4.15).
\[
\left| \mathbb{E} \left[ \xi(\lambda) (0) \xi(\lambda) (1) \right] - \mathbb{E} \left[ \xi(\lambda) (0) \xi(\lambda) (1) \right] \right| \leq \left| \mathbb{E} \left[ (\xi(\lambda) (0) - \xi^{(\lambda)}_{[0,r]} (0)) \xi(\lambda) (1) \right] \right| + \left| \mathbb{E} \left[ \xi^{(\lambda)}_{[r,r]} (0) (\xi(\lambda) (1) - \xi^{(\lambda)}_{[0,r]} (1)) \right] \right|. \quad (4.20)
\]
We derive an upper bound for the first term in the rhs of (4.20), the second term being treated identically. Using Hölder’s inequality, we obtain
\[
\left| \mathbb{E} \left[ (\xi(\lambda) (0) - \xi^{(\lambda)}_{[r,r]} (0)) \xi(\lambda) (1) \right] \right| = \left| \mathbb{E} \left[ (\xi(\lambda) (0) - \xi^{(\lambda)}_{[r,r]} (0)) \xi(\lambda) (1) \mathbb{1}_{[\xi(\lambda) (0) \neq \xi^{(\lambda)}_{[r,r]} (0)]} \right] \right| \leq \mathbb{E} \left[ |\xi(\lambda) (0) - \xi^{(\lambda)}_{[r,r]} (0)|^3 \right]^{1/3} \mathbb{E} \left[ |\xi(\lambda) (1)|^3 \right]^{1/3} \mathbb{P} (\xi(\lambda) (0) \neq \xi^{(\lambda)}_{[r,r]} (0))^{1/3}.
\]
The convergence (4.15) is then a consequence of Proposition 3.6 and Lemma 4.1. The convergence (4.17) is derived analogously to (4.10) by using [9, Theorem 5.4] and Lemma 4.1. This proves Proposition 4.4.

Lemma 4.5 below asserts that the correlation function $c^{(\lambda)}_{n,k}$ decays exponentially fast as a function of the heights of the two points and of the distance between them. This means in particular that the scores get closer to being independent as the distance between the points increases. The proof of Lemma 4.5 relies on Proposition 3.6 and Lemma 4.1 and is identical to the proof of [15, Lemma 4.8]. For that reason, it is omitted.

**Lemma 4.5** For all $n \geq 1$, there exist $c_1, \ldots, c_4 > 0$ such that for any $h > 0$, $(v_1, h_1) \in \mathbb{R}^{d-1} \times \mathbb{R}_+$, $p \geq 1$ and $\lambda \in [1, \infty]$ we have
\[
|c^{(\lambda)}_{n,k}((0,h_0),(v_1,h_1))| \leq c_1 h_0^{c_2} h_1^{c_3} \exp \left( -c_4 \left( \|v_1\|^{d+1} + h_0^{d+1} + h_1^{d+1} \right) \right).
\]
5 Proofs of the main results

In this section, Theorems 2.10–2.13 are proved. We recall that they include the statements on the limiting expectations and variances of Theorems 1.1 and 1.2. We emphasize here that the central limit theorems from Theorems 1.1 and 1.2 are also consequences of the stabilization technique. Indeed, stabilization properties lead to the construction of a dependency graph after discretization of the space and after conditioning on a high probability event. The dependency graph structure combined with moment bounds induces a Gauss approximation thanks to Chen and Shao’s work [19]. Nevertheless, we have chosen to omit the proof of the central limit theorems as it is the exact replicate line by line of [13, pages 93–98] when the convex hull is replaced by the \( n \)-th layer of the peeling.

5.1 Results on \( k \)-dimensional faces

Proof of Theorem 2.10
Proof of the convergence of the normalized expectation. The first step consists in taking the expectation in (2.10) and using the Mecke formula to get

\[
\mathbb{E}[N_{n,k,\lambda}] = \lambda \int_{\mathbb{R}^d} \mathbb{E}[\xi_{n,k}(x, \mathcal{P}_\lambda)] dx.
\]

Let us introduce \( e_d = (0, \ldots, 0, 1) \). By rotation-invariance of \( \mathbb{E}[\xi_{n,k}(x, \mathcal{P}_\lambda)] \), we obtain

\[
\mathbb{E}[\xi_{n,k}(x, \mathcal{P}_\lambda)] = \mathbb{E}[\xi_{n,k}(|x|e_d, \mathcal{P}_\lambda)].
\]

Then we apply a change of coordinates in spherical coordinates to get

\[
\mathbb{E}[N_{n,k,\lambda}] = \lambda \int_{\mathbb{S}^{d-1}} \int_0^1 \mathbb{E}[\xi_{n,k}(re_d, \mathcal{P}_\lambda)] r^{d-1} dr d\sigma_{d-1}(u), \tag{5.1}
\]

where \( \sigma_{d-1} \) is the unnormalized area measure on \( \mathbb{S}^{d-1} \).

Recall that for every \( h > 0 \), \( \xi_{n,k}((0, h), \mathcal{P}^{(\lambda)}) = \xi_{n,k}([T^{(\lambda)}]^{-1}((0, h)), \mathcal{P}_\lambda) \), see (2.12). Consequently, an application of the change of variables \( h = \lambda^{-\frac{2}{d+1}}(1 - r) \) in (5.1) leads to

\[
\mathbb{E}[N_{n,k,\lambda}] = \lambda^{\frac{d+2}{d+1}} \int_{\mathbb{S}^{d-1}} \int_0^{\lambda^{-\frac{2}{d+1}}} \mathbb{E}[\xi_{n,k}^{(\lambda)}((0, h), \mathcal{P}^{(\lambda)})] \lambda^{-\frac{2}{d+1}} (1 - \lambda^{-\frac{2}{d+1}} h)^{d-1} dh d\sigma_{d-1}(u) \\
= \lambda^{\frac{d+1}{d+1}} \int_{\mathbb{S}^{d-1}} \int_0^{\lambda^{-\frac{2}{d+1}}} \mathbb{E}[\xi_{n,k}^{(\lambda)}((0, h), \mathcal{P}^{(\lambda)})] (1 - \lambda^{-\frac{2}{d+1}} h)^{d-1} dh d\sigma_{d-1}(u). \tag{5.2}
\]
We now wish to use the dominated convergence theorem. Lemma 4.3 implies that for any $h > 0$

$$\mathbb{E}[\xi^{(\lambda)}_{n,k}((0, h), \mathcal{P}^{(\lambda)})](1 - \lambda^{-\frac{2}{d+1}})h^{d-1} \mathbb{1}_{0 \leq h \leq \lambda^{rac{2}{d+1}}} \xrightarrow{\lambda \to +\infty} \mathbb{E}[\xi^{(\infty)}_{n,k}((0, h), \mathcal{P})].$$

Thanks to Lemma 4.1, the integrand in the rhs of (5.2) is bounded from above by an integrable function of $h$, i.e.

$$\mathbb{E}[\xi^{(\lambda)}_{n,k}((0, h), \mathcal{P}^{(\lambda)})](1 - \lambda^{-\frac{2}{d+1}})h^{d-1} \mathbb{1}_{0 \leq h \leq \lambda^{rac{2}{d+1}}} \leq c_1 \exp(-c_2 h^{\frac{d+1}{2}}).$$

Applying the dominated convergence theorem in (5.2) shows that

$$\lim_{\lambda \to \infty} \lambda^{-\frac{d-1}{d+1}} \mathbb{E}[N_{n,k,\lambda}] = \text{Vol}_{d-1}(\mathbb{S}^{d-1}) \int_{0}^{\infty} \mathbb{E}[\xi^{(\infty)}_{n,k}((0, h), \mathcal{P})]dh < \infty. \quad (5.3)$$

**Proof of the positivity of the limiting expectation.** Noticing that

$$\mathbb{E}[\xi^{(\infty)}_{n,k}((0, h), \mathcal{P})] \geq \frac{1}{k+1} \mathbb{P}\left((0, h_0) \in \partial \Phi_n^{(\infty)}(\mathcal{P} \cup \{(0, h_0))\right),$$

we deduce that the positivity of the rhs of (5.3) is a consequence of Lemma 5.1 below.

\[ \Box \]

**Lemma 5.1** For any $(0, h_0)$ with $h_0 > 0$ and any $n \geq 1$:

$$\mathbb{P}\left((0, h_0) \in \partial \Phi_n^{(\infty)}(\mathcal{P} \cup \{(0, h_0))\right) \neq 0.$$

**Proof** Let us write $w_0 := (0, h_0)$ and put $\mathcal{T}_0 := \{w_0\}$. Our first step is purely deterministic and consists in constructing for $n = 2$ an idealized point configuration which puts $w_0$ on the second layer. We then extend the procedure for every $n > 2$ to get a point set which puts $w_0$ on the $n$-th layer. In a second step, we introduce randomness and show that this property is stable with respect to a small random perturbation of the configuration.

For each $i \in \{1, \ldots, d - 1\}$, we write $w_{(i,+)} = (\sqrt{n-1} e_i, \frac{h_0}{\sqrt{n-1}})$ and $w_{(i,-)} = (-\sqrt{n-1} e_i, \frac{h_0}{\sqrt{n-1}})$. A direct calculation shows that for any $i$, $\Pi^\perp(w_{(i,+)}) \subseteq \Pi^\perp(0, h_0)$, $\Pi^\perp(w_{(i,-)}) \subseteq \Pi^\perp(0, h_0)$ and $\Pi^\perp(w_{(i,s)}) \cap \Pi^\perp(w_{(j,s)}) = \emptyset$ for any $i, j \in \{1, \ldots, d - 1\}$, $s \in \{+, -\}$ such that $(i, s) \neq (j, s)$.

Let us consider the deterministic point set $\mathcal{T}_1 := \{w_0\} \cup \{w_{(i,s)} : i \in \{1, \ldots, d - 1\}, s \in \{+, -\}\}$ and describe the peeling of $\mathcal{T}_1$. The points $w_{(i,s)}$ are on the first layer because each $\Pi^\perp(w_{(i,s)})$ is empty. Any downward paraboloid whose boundary goes through $w_0$ contains at least half of $\Pi^\perp(w_0)$ by Lemma 3.1 so it contains at least one of the $w_{(i,s)}$. This implies in turn that $w_0$ is not on the first layer. Furthermore $\Pi^\perp(w_0)$ only contains points on the first layer so $w_0$ is on the second layer.

We are going to iterate this construction by induction to obtain for every $n > 2$ an extended deterministic point configuration $\mathcal{T}_{n-1} = \{w_a : a \in \cup_{i=0}^{n-1}(\{1, \ldots, d - 1\} \times... \}. \quad \square
{+,-})^l$, with the convention $(\cdot)^0 = \{0\}$, which guarantees that $w_0$ is on the $n$-th layer of the peeling of $T_{n-1}$ and that for any $1 \leq l \leq (n-1)$, $T_l \setminus T_{l-1}$ is included on its $(n-l)$-th layer. To do so, let us assume that we have constructed $T_{n-2}$ with that property. Let us fix $a \in (\{1, \ldots, d-1\} \times \{+,-\})^{n-2}$ and write $w_a = (v, h)$. We define $w_a, (i, +) := (v + \frac{1}{2}\sqrt{\frac{h_0}{8^{n-2}}} e_i, \frac{h}{8^{n-1}})$ and $w_a, (i, -) := (v - \frac{1}{2}\sqrt{\frac{h_0}{8^{n-2}}} e_i, \frac{h}{8^{n-1}})$.

The construction is just a rescaling of the situation described for the case $n = 2$ with $w_a$ playing the role of $w_0$ and $w_a, (i, s)$ that of $w(i, s)$. Consequently, we get the same properties, i.e. for any $(i, s)$

$$\Pi^\perp(w_a, (i, s)) \subseteq \Pi^\perp(w_a) \quad (5.4)$$

and for $(i, s_1) \neq (j, s_2)$

$$\Pi^\perp(w_a, (i, s_1)) \cap \Pi^\perp(w_a, (j, s_2)) = \emptyset. \quad (5.5)$$

If we put an edge from $w_a$ to each $w_a, (i, s)$ then we endow $T_{n-1}$ with a structure of tree with root $w_0$, see Fig. 8 in the case $n = 3$ in dimension 2 and 3. We also take the convention $T_{-1} = \emptyset$.

The construction has been done such that for every $l \in \{0, \ldots, (n-1)\}$, each point $w_a \in (T_l \setminus T_{l-1})$ is on the $(n-l)$-th layer of the peeling of $T_{n-1}$.

We prove now by downward induction the stability of the property above when the idealized point set is subject to a small random perturbation. Let us fix $\varepsilon > 0$ and consider the event

$$A_n = \cap_{w_a \in T_{n-1}\setminus\{w_0\}} \{(\mathcal{P} \cap B(w_a, \varepsilon) = 1) \cap \{\mathcal{P} \cap (\Pi^\perp(w_0) \cup \cup_{w_a \in T_{n-1}} B(w_a, \varepsilon)) = \emptyset\} \}.$$

On the event $A_n$, for every $w_a \in T_{n-1}$ we denote by $\tilde{w}_a$ the unique point belonging to $\mathcal{P} \cap B(w_a, \varepsilon)$ and call it a perturbed point from the tree (with same depth as the original point $w_a$). We then assert and prove below that the stability occurs, i.e. that the perturbed point $\tilde{w}_a$ is on the $(n-l)$-th layer of the peeling of $\mathcal{P} \cup \{w_0\}$ as soon as the original point $w_a$ is at depth $l$ in $T_{n-1}$.
We make the following preliminary observation: the calibrations in the construction of the tree $T_{n-1}$ allow us to strengthen (5.4) and (5.5) by claiming that for $\varepsilon$ small enough, the $\varepsilon$-neighborhood of $\Pi^\downarrow(w_a)$ is included in $\Pi^\downarrow(w_b)$ for any $w_a \in T_{n-1}$ with parent $w_b$ and that the $\varepsilon$-neighborhoods of the downward parabolas associated with two distinct perturbed points at same depth do not meet.

We start with our base case, which is depth $(n-1)$. For any $a \in (\{1, \ldots, d - 1\} \times \{+, -\})^{n-1}$, thanks to the observation above, the perturbed point $\tilde{w}_a$ satisfies that $\Pi^\downarrow(\tilde{w}_a)$ does not intersect $P$ when $\varepsilon$ is small enough. This shows that all perturbed points at depth $(n-1)$ are extreme.

Now we assume that for some $l \in \{1, \ldots, n-1\}$, each perturbed point at depth $k$ is on the $(n-k)$-th layer for every $l \leq k \leq (n-1)$. We consider a perturbed point $\tilde{w}_a$ at depth $(l-1)$, which means $a \in (\{1, \ldots, d - 1\} \times \{+, -\})^{l-1}$. Because of the preliminary observation, for $\varepsilon$ small enough, the downward paraboloid $\Pi^\downarrow(\tilde{w}_a)$ only contains points that can be written $\tilde{w}_{a,b}$ for some $b \in (\{1, \ldots, d - 1\} \times \{+, -\})^p$ and $1 \leq p \leq (n-l)$. Thus $\tilde{w}_a$ is at most on the $(n-l+1)$-th layer.

Moreover, noticing that any downward paraboloid whose boundary goes through $\tilde{w}_a$ contains at least one of the $\tilde{w}_{a,(i,s)}$, which are on the $(n-l)$-th layer. This shows that $\tilde{w}_a$ is on the $(n-l+1)-st$ layer. A finite induction on $l$ thus gives us that on the event $A_n$, $w_0$ is on the $n$-th layer.

It remains to show that $\mathbb{P}(A_n) > 0$. Using the Poisson property and (5.4)–(5.5), we get

$$
\mathbb{P}(A_n) = \mathbb{P}(P \cap (\Pi^\downarrow(w_0) \setminus \cup_{w_a \in T_{n-1}} B(w_a, \varepsilon)) = \emptyset ) 
\prod_{w_a \in T_{n-1} \setminus \{w_0\}} \mathbb{P}(\#(P \cap B(w_a, \varepsilon)) = 1) > 0.
$$

\[\Box\]

**Proof of Theorem 2.11** Proof of the convergence of the normalized variance. In the same way as for the expectation asymptotics, the first idea consists in using Mecke’s formula. Combining it with Fubini’s theorem and writing $\xi'_{n,k,\lambda}(x, \mathcal{P}_\lambda)$ for the same functional as $\xi_{n,k,\lambda}(x, \mathcal{P}_\lambda)$ save for the fact that $x$ is not added to the process, we get

\[\text{Var}(N_{n,k,\lambda}) = \mathbb{E}\left[\left(\sum_{x \in \mathcal{P}_\lambda} \xi'_{n,k,\lambda}(x, \mathcal{P}_\lambda)\right)^2\right] - \mathbb{E}\left[\sum_{x \in \mathcal{P}_\lambda} \xi'_{n,k,\lambda}(x, \mathcal{P}_\lambda)\right]^2 = \mathbb{E}\left[\sum_{x \in \mathcal{P}_\lambda} \xi'_{n,k,\lambda}(x, \mathcal{P}_\lambda)^2\right] + \mathbb{E}\left[\sum_{x,y \in \mathcal{P}_\lambda, x \neq y} \xi'_{n,k,\lambda}(x, \mathcal{P}_\lambda)\xi'_{n,k,\lambda}(y, \mathcal{P}_\lambda)\right] - \mathbb{E}\left[\sum_{x \in \mathcal{P}_\lambda} \xi'_{n,k,\lambda}(x, \mathcal{P}_\lambda)^2\right] = I_1(\lambda) + I_2(\lambda)
\]
where

\[ I_1(\lambda) := \lambda \int_{\mathbb{R}^d} \mathbb{E} \left[ \xi_{n,k,\lambda}(x, \mathcal{P}_\lambda)^2 \right] dx \quad \text{and} \quad I_2(\lambda) := \lambda^2 \int_{(\mathbb{R}^d)^2} c_{n,k,\lambda}(x, y) dxdy. \]

with

\[ c_{n,k,\lambda}(x, y) = \mathbb{E} \left[ \xi_{n,k,\lambda}(x, \mathcal{P}_\lambda \cup \{y\}) \xi_{n,k,\lambda}(y, \mathcal{P}_\lambda \cup \{x\}) \right] \]

\[ - \mathbb{E} \left[ \xi_{n,k,\lambda}(x, \mathcal{P}_\lambda) \right] \mathbb{E} \left[ \xi_{n,k,\lambda}(y, \mathcal{P}_\lambda) \right]. \]

We treat \( I_1(\lambda) \) as in the proof of Theorem 2.10 to get

\[ \lim_{\lambda \to +\infty} \lambda^{-\frac{d}{d+1}} I_1(\lambda) = I_1 \]

where we recall the definition of \( I_1 \) at (2.14). We now prove the convergence of \( \lambda^{-\frac{d}{d+1}} I_2(\lambda) \). We follow line by line the method used in [13, calculation of II on pages 92-93], i.e. rewriting in spherical coordinates, then use of a change of variables provided by the scaling transformation \( T^{(\lambda)} \), to obtain that

\[ I_2(\lambda) = \lambda^{\frac{d-1}{2}} \int_{\mathbb{S}^{d-1}} \int_0^{\frac{\lambda}{\sqrt{\tau+1}}} \int_{\mathbb{S}^{d-1}} f^{(\lambda)}(u_0, h_0, v_1, h_1) dv_1 dh_1 dh_0 d\sigma_{d-1}(u_0) \]

where

\[ f^{(\lambda)}(u_0, h_0, v_1, h_1) := (1 - \lambda^{-\frac{2}{d+1}} h_0)^{d-1} \]

\[ \sin^{d-2} \left( \lambda^{-\frac{1}{d+1}} |v_1| \right) (1 - \lambda^{-\frac{2}{d+1}} h_1)^{d-1} c_{n,k}^{(\lambda)}((0, h_0), (v_1, h_1)), \]

with \( c_{n,k}^{(\lambda)} \) defined at (2.13).

It remains to apply the dominated convergence theorem. Using Lemma 4.5, we obtain

\[ |f^{(\lambda)}(u_0, h_0, v_1, h_1)| \leq c_1 h_0^{c_2} h_1^{c_3} \exp \left( -c_4 \left( \|v_1\|^{d+1} + h_0^{d+1} + h_1^{d+1} \right) \right) \]

which is integrable on \( \mathbb{S}^{d-1} \times \mathbb{R}_+ \times \mathbb{R}^{d-1} \times \mathbb{R}_+ \). We deduce from Proposition 4.4 that

\[ \lim_{\lambda \to \infty} f^{(\lambda)}(u_0, h_0, v_1, h_1) = c_{n,k}^{(\infty)}((0, h_0), (v_1, h_1)). \]

This implies that

\[ \lim_{\lambda \to \infty} \lambda^{-\frac{d}{d+1}} I_2(\lambda) = I_2, \]
where \( I_2 \) has been defined at (2.15).

**Proof of the positivity of the limiting variance.** This proof is essentially adapted from [17, Section 4.5]. The main difference is that we make sure that our points are on the \( n \)-th layer instead of being extremal.

Similarly to what is done in [13, Lemma 7.6], we can use the same arguments as in the proof of Theorem 2.11 to show that

\[
\lim_{\lambda \to \infty} \lambda^{-\frac{d-1}{d+1}} \text{Var}[N_{n,k,\lambda}] = \lim_{\lambda \to \infty} \lambda^{-\frac{d-1}{d+1}} \text{Var}[\tilde{N}_{n,k,\lambda}] \quad (5.6)
\]

where we write \( \tilde{N}_{n,k,\lambda} := \sum_{w \in P \cap W_{\lambda}} \xi^{(\infty)}(w, P) \).

Our strategy to prove that the limit in the rhs of (5.6) is positive is the following: we start by discretizing \( W_{\lambda} \) and construct in each parallelepiped of that discretization two different configurations, said to be good, which have a positive probability to occur and which give birth to two different values for the local number of \( k \)-faces of the \( n \)-th layer. Then we check that this counting is not affected by the external configuration and finally, we find a lower bound for the total variance conditional on the intersection of the point process with the outside of the parallelepipeds which contain one of the two good configurations.

**Step 1. Construction of a good configuration in a thin parallelepiped.** First, we consider a cube \( Q \subseteq \mathbb{R}^{d-1} \) and we take \( \rho \in (0, \infty) \) smaller than the diameter of \( Q \). We take \( \delta > 0 \) sufficiently small such that the paraboloids \( \Pi^+(w) \) are pairwise disjoint for \( w \) belonging to the grid \( (\rho \mathbb{Z}^{d-1} \cap Q) \times \{\delta\} \). For each \( w \in (\rho \mathbb{Z}^{d-1} \cap Q) \times \{\delta\} \), we make the same tree construction as in the proof of Lemma 5.1 inside \( \Pi^+(w) \). We obtain a forest that we call \( T_{n,\rho} \). In particular, the construction ensures that all points \( w \in (\rho \mathbb{Z}^{d-1} \cap Q) \times \{\delta\} \) belong to the \( n \)-th layer of \( T_{n,\rho} \). Let us write \( F_{n,k}(Q, \rho, \delta) \) for the number of \( k \)-faces of the \( n \)-th layer of \( (P \setminus (Q \times [0, \infty))) \cup T_{n,\rho} \) going through any \( w \in (\rho \mathbb{Z}^{d-1} \cap Q) \times \{\delta\} \). If we ignore the points of \( P \setminus (Q \times [0, \infty)) \), as the diameter of \( Q \) gets large compared to \( \rho \), boundary effects become negligible and we get

\[
F_{n,k}(Q, \rho/2, \delta) \sim 2^{d-1} F_{n,k}(Q, \rho, \delta).
\]

Then we consider \( \varepsilon > 0 \) such that

\[
\delta + \varepsilon \leq \frac{\rho^2}{8}. \quad (5.7)
\]

This guarantees in particular that for any \( w = (v, \delta + \varepsilon) \) and \( w' = (v', \delta + \varepsilon) \) with \(|v - v'| \geq \rho\), we have \( \Pi^+(w) \cap \Pi^+(w') = \emptyset \). As in the proof of the positivity of the expectation, we consider a random perturbation of the points of \( T_{n,\rho} \) by at most \( \varepsilon \) for the Euclidean distance, i.e. we assume that \( P \cap B(w, \varepsilon) \) consists of one point for each \( w \in T_{n,\rho} \). We notice that the obtained perturbed points have a height at most equal to \( \delta + \varepsilon \) and are distant by at most \( 2\rho \) when \( \varepsilon < \rho/2 \). Consequently, for \( \varepsilon \) small enough, the maximal height of \( (Q \times [0, \infty)) \setminus \bigcup_{w' \in P \cap w \in T_{n,\rho} B(w, \varepsilon)} \Pi^+(w') \) is smaller than \( \alpha \) where \( \alpha \) is the maximal height of a point in \( (Q \times [0, \infty)) \setminus \bigcup_{w \in (Q \cap 2\rho \mathbb{Z}^{d-1}) \times [\delta + \varepsilon]} \Pi^+(w) \). In particular,
we claim that there is a constant $c_\alpha > 1$ depending only on dimension $d$ such that
\[
\alpha \leq c_\alpha \rho^2. \tag{5.8}
\]
Indeed, up to boundary effects, the set of apices of down paraboloids which contain $2^{d-1}$ points of $Q \cap 2\rho \mathbb{Z}^{d-1} \times \{\delta + \epsilon\}$ is located on a translated dual grid at height $((d-1)\frac{\rho^2}{2} + \delta + \epsilon)$, see Fig. 9.

Consequently, let us consider the event
\[
A_{n,\rho} = \cap_{w \in T_{n,\rho}} \{\#(\mathcal{P} \cap B(w, \epsilon)) = 1\} \cap \{(\mathcal{P} \cap ((Q \times [0, \alpha]) \setminus \cup_{w \in T_{n,\rho}} B(w, \epsilon)) = \emptyset\}. 
\]
Let us write $F_{n,k}(Q, \rho, \delta, \epsilon)$ for the total number of $k$-faces of the $n$-th layer of $\mathcal{P}$ going through at least one point in $\mathcal{P} \cap \cup_{w \in (\rho \mathbb{Z}^{d-1} \cap Q) \times \{\delta\}} B(w, \epsilon)$. Conditional on $A_{n,\rho}$ and when the points of $\mathcal{P} \cap (Q \times [0, \alpha])$ are ignored, for $\epsilon$ small enough, this quantity is in fact equal to $F_{n,k}(Q, \rho, \delta, \epsilon)$ and we keep the relation
\[
F_{n,k}(Q, \rho/2, \delta, \epsilon) \sim 2^{d-1} F_{n,k}(Q, \rho, \delta, \epsilon). \tag{5.9}
\]

**Step 2. Influence of the points outside of the thin parallelepiped $Q \times [0, \alpha]$.** For any closed set $C \subseteq \mathbb{R}^{d-1}$, we define for any $\gamma > 0$, $C^{(\gamma)} := \{x \in C : d(x, \partial C) > \gamma\}$. We claim that on $A_{n,\rho}$, for any $w \in \mathcal{P} \cap (Q^{(\rho)} \times [0, \alpha])$, the status of $w$ does not depend on points outside $Q \times [0, \alpha]$, i.e.
\[
\ell^{(\infty)}(w, \mathcal{P} \cap (Q \times [0, \alpha])) = \ell^{(\infty)}(w, \mathcal{P}).
\]
This is due to the fact that the condition (5.7) guarantees that the down paraboloids with apices at points from $\mathcal{P} \cap (Q^{(\rho)} \times [0, \alpha])$ are included in $Q \times [0, \alpha]$.

Moreover, for $c = \sqrt{2c_\alpha} + 2$, we assert that the facial structure around any point inside $\mathcal{P} \cap (Q^{(c\rho)} \times [0, \alpha])$ which belongs to the $n$-th layer of the peeling of $\mathcal{P}$ does not depend on points outside $Q \times [0, \alpha]$. Indeed, let us consider $w \in \mathcal{P} \cap (Q^{(c\rho)} \times [0, \alpha])$. We choose $(d-1)$ points from $\mathcal{P} \cap (Q^{(\sqrt{2c_\alpha} \rho)} \times [0, \alpha])$ which share a common facet of.
the $n$-th layer of the peeling of $P \cap (Q \times [0, \alpha])$. The down paraboloid which contains this facet has an apex in $Q(\sqrt{2\pi n \rho}) \times [0, \alpha]$. Consequently, thanks to (5.8), that down paraboloid is included in $Q \times [0, \alpha]$, which implies that the facet containing $w$ and the $(d - 1)$ other points is a facet of the $n$-th layer of the peeling of $P$.

Step 3. Discretization of $W_\lambda$ and lower bound for the variance. We are now ready to discretize $W_\lambda$ and isolate the good parallelepipeds from the discretization, according to the two previous steps. We choose $\delta$ and $\varepsilon$ which satisfy (5.7) with the choice $\rho = 1$.

We take a large positive number $M$ and we partition $\left[ -\frac{\lambda}{M}, \frac{\lambda}{M} \right]^{d-1}$ into $L := \left[ \frac{\lambda}{M}, \frac{\lambda}{M} \right]^{d-1}$ cubes $Q_1, \ldots, Q_L$. We consider the cubes $Q_i$ satisfying the following properties:

(a) For each $z \in (\mathbb{Z}^{d-1} \cap (Q_i \setminus Q_i^{(e)})) \times \{\delta\}$, $P \cap B(z, \varepsilon)$ is a singleton and is put on the $n$-th layer using the tree construction associated with $\mathcal{T}_{n,1}$ and the perturbation of each point by at most $\varepsilon$ as in Step 1.

(b) One of these two conditions holds:

1. For each $z \in (\mathbb{Z}^{d-1} \cap Q_i^{(e)}) \times \{\delta\}$, $P \cap B(z, \varepsilon)$ is a singleton and this point is put on the $n$-th layer as in property (a).

2. For each $z \in (\frac{1}{2}\mathbb{Z}^{d-1} \cap Q_i^{(e)}) \times \{\delta\}$, $P \cap B(z, \varepsilon)$ is a singleton and this point is put on the $n$-th layer as before.

(c) Aside from the points described above, $P$ has no point in $Q_i \times [0, \alpha]$.

After a possible relabeling, let $I := \{1, \ldots, K\}$ be the indices of cubes partitioning $\left[ -\frac{\lambda}{2}, \frac{\lambda}{2} \right]^{d-1}$ that verify properties (a) to (c). Since any cube has a positive probability to verify these properties, we have

$$\mathbb{E}[K] \geq c\lambda^{\frac{d-1}{2}}.$$ (5.10)

Let $\mathcal{F}_\lambda$ be the $\sigma$-algebra generated by $I$, the positions of points in $W_\lambda \setminus (\bigcup_{i \in I} Q_i^{(e)} \times [0, \alpha])$ and the scores $\hat{\xi}_{n,k}^{(\infty)}(x, P)$ at these points. For each $i \in I$ we claim that

$$\text{Var} \left[ \sum_{x \in P \cap (Q_i \times [0, \alpha])} \hat{\xi}_{n,k}^{(\infty)}(x, P) \bigg| \mathcal{F}_\lambda \right] = \text{Var} \left[ \sum_{x \in P \cap (Q_i^{(e)} \times [0, \alpha])} \hat{\xi}_{n,k}^{(\infty)}(x, P) \bigg| \mathcal{F}_\lambda \right] \geq c_0.$$ (5.11)

Indeed, either condition (b1) or condition (b2) occurs in $Q_i^{(e)} \times [0, \alpha]$, each with positive probability. Moreover, we observe that $\sum_{x \in P \cap (Q_i \times [0, \alpha])} \hat{\xi}_{n,k}^{(\infty)}(x, P)$ is larger when (b2) is satisfied. This is due to the scaling result (5.9) which implies that the contribution of points inside $Q_i^{(e)} \times [0, \alpha]$ provides a quantity almost $2^{d-1}$ times larger when (b2) is satisfied.
Since only scores in $\bigcup_{i \in I} Q_i \times [0, \alpha]$ have any variability conditional on $\mathcal{F}_\lambda$ we get

$$\text{Var}[\tilde{N}_{n,k,\lambda}] = \text{Var}[\mathbb{E}[\tilde{N}_{n,k,\lambda}|\mathcal{F}_\lambda]] + \mathbb{E}[\text{Var}[\tilde{N}_{n,k,\lambda}|\mathcal{F}_\lambda]]$$

$$\geq \mathbb{E}\left[\text{Var}\left[\tilde{N}_{n,k,\lambda}|\mathcal{F}_\lambda\right]\right]$$

$$= \mathbb{E}\left[\text{Var}\left[\sum_{i \in I} \sum_{x \in P \cap (Q_i^{(c)} \times [0,\alpha])} \xi_{n,k}^{(\infty)}(x, P)|\mathcal{F}_\lambda\right]\right].$$

Then the sums of scores in $Q_i^{(c)} \times [0, \alpha]$ and $Q_j^{(c)} \times [0, \alpha]$ for $i \neq j$ are independent conditional on $\mathcal{F}_\lambda$ since the scores in $Q_i^{(c)} \times [0, \alpha]$ only depend on points in $Q_i \times [0, \alpha]$. Thus we can write

$$\text{Var}[\tilde{N}_{n,k,\lambda}] \geq \sum_{i \in I} \mathbb{E}\left[\text{Var}\left[\sum_{x \in P \cap (Q_i \times [0,\alpha])} \xi_{n,k}^{(\infty)}(x, P)|\mathcal{F}_\lambda\right]\right]$$

$$\geq c_0 \mathbb{E}[K]$$

$$\geq c\lambda^{-\frac{d-1}{d+1}}.$$

where the second inequality comes from (5.11) applied to each $Q_i$ and the last inequality comes from (5.10). Thanks to (5.6), this proves the positivity of the limiting variance. \square

### 5.2 Results on intrinsic volumes

We define the score and two-point correlation function in the case of intrinsic volumes by following closely the method of [13, pp. 54–55], which relies on Kubota’s formula, see [37, equation (6.11)]. For convenience, let us write $\text{conv}_{n,\lambda} := \text{conv}_{n}(P_\lambda)$ and let us denote by $\kappa_m$ the volume of the $m$-dimensional unit ball. By Kubota’s formula applied to $\text{conv}_{n,\lambda}$, we get

$$V_k(\text{conv}_{n,\lambda}) = \frac{d! \kappa_d}{k! \kappa_k (d-k)! \kappa_{d-k}} \int_{G(d,k)} \text{Vol}_k(\text{conv}_{n,\lambda}|L) d\nu_k(L) \tag{5.12}$$

where $\nu_k$ is the normalized Haar measure on the $k$-th Grassmanian $G(d,k)$ of $\mathbb{R}^d$ and $\text{conv}_{n,\lambda}|L$ is the orthogonal projection of $\text{conv}_{n,\lambda}$ onto $L$. For every $x \in \mathbb{R}^d \setminus \{0\}$ we define $\vartheta_L(x, \text{conv}_{n,\lambda}) := 1_{\{x \notin \text{conv}_{n,\lambda}|L\}}$ and the projection avoidance functionals

$$\vartheta_k(x, \text{conv}_{n,\lambda}) := \int_{G(\text{lin}[x],k)} \vartheta_L(x, \text{conv}_{n,\lambda}) d\nu^{\text{lin}[x]}_k(L)$$

where $\text{lin}[x]$ is the linear space spanned by $x$, $G(\text{lin}[x], k)$ is the set of all $k$-dimensional linear subspaces of $\mathbb{R}^d$ containing $\text{lin}[x]$ and $\nu^{\text{lin}[x]}_k$ is the normalized Haar measure on $\mathbb{R}^d$. 

Springer
Combining (5.12) and Fubini’s theorem we can rewrite the defect $k$-th intrinsic volume of $\text{conv}_{n,\lambda}$ as

$$V_{n,k,\lambda} = \frac{(d-1)}{\kappa_{d-k}} \int_{\mathbb{R}^d} \vartheta_k(x, \text{conv}_{n,\lambda}) \frac{dx}{|x|^{d-k}}.$$

The functional $V_{n,k,\lambda}$ can then be written as a sum of scores, i.e.

$$V_{n,k,\lambda} = \sum_{x \in \mathcal{P}_\lambda} \xi_{V,n,k}(x, \mathcal{P}_\lambda)$$

with

$$\xi_{V,n,k}(x, \mathcal{P}_\lambda) := \begin{cases} \frac{(d-1)}{d\kappa_{d-k}} \int_{\text{cone}_n(x, \mathcal{P}_\lambda)} \vartheta_k(y, \text{conv}_{n}(\mathcal{P}_\lambda \cup \{x\})) \frac{dy}{|y|^{d-k}} & \text{if } x \in \partial \text{conv}_{n,\lambda} \\ 0 & \text{otherwise} \end{cases}$$

where $\text{cone}_n(x, \mathcal{P}_\lambda) := \{ry : r > 0 \text{ and } y \in \mathcal{F}_{n,d-1}(x, \mathcal{P}_\lambda)\}$. We denote by

$$\xi^{(\lambda)}_{V,n,k}(x, \mathcal{P}^{(\lambda)}) := \lambda \xi_{V,n,k,\lambda}([T^{(\lambda)}]^{-1}(x), \mathcal{P}_\lambda)$$

(5.13)

their rescaled counterparts, see [13, page 84] for an explanation on the factor $\lambda$. Let us explain how to define the limit versions of the rescaled scores. For a point $w = (v, h) \in \mathbb{R}^{d-1} \times \mathbb{R}_+$ we write $w^\perp$ for the set $\{v\} \times \mathbb{R}_+$. We denote by $A(w^\perp, k)$ the set of all $k$-dimensional affine spaces in $\mathbb{R}^{d-1} \times \mathbb{R}_+$ containing $w^\perp$. For any $k$ and any affine space $L \in A(w^\perp, k)$ we define the orthogonal parabolic volume

$$\Pi^\perp(w, L) := (w \oplus L^\perp) \cap \Pi^\perp(w).$$

We put $\vartheta^{(\infty)}_{n,L}(w) = 1$ if $\Pi^\perp(w, L) \cap \Phi_n(\mathcal{P}) = \emptyset$ and 0 otherwise. Then we define

$$\vartheta^{(\infty)}_{n,k}(w) := \int_{A(w^\perp, k)} \vartheta^{(\infty)}_{n,L}(w) d\mu_k^{w^\perp}(L)$$

where $\mu_k^{w^\perp}$ is the normalized Haar measure on $A(w^\perp, k)$. We are finally able to define the limit score

$$\xi^{(\infty)}_{V,n,k}(w, \mathcal{P}) := \frac{(d-1)}{d\kappa_{d-k}} \int_{\text{v-cone}(\mathcal{F}^{(\infty)}_{n,d-1}(w, \mathcal{P}))} \vartheta^{(\infty)}_{n,k}(w') dw'$$

(5.14)

where $\text{v-cone}(\mathcal{F}^{(\infty)}_{n,d-1}(w, \mathcal{P})) := \{(w', h'), \exists h'' (w', h'') \in \mathcal{F}^{(\infty)}_{n,d-1}(w)\}$.

For any $\lambda \in (0, \infty]$, the corresponding two-point correlation function is then defined by the identity...
\[ c_{V,n,k}^{(\lambda)}((0, h_0), (v_1, h_1)) := \mathbb{E}[\xi_{V,n,k}^{(\lambda)}((0, h_0), \mathcal{P}^{(\lambda)} \cup \{(v_1, h_1)\})\xi_{V,n,k}^{(\lambda)}((v_1, h_1), \mathcal{P}^{(\lambda)} \cup \{(0, h_0)\})] - \mathbb{E}[\xi_{V,n,k}^{(\lambda)}((0, h_0), \mathcal{P}^{(\lambda)})] \mathbb{E}[\xi_{V,n,k}^{(\lambda)}((v_1, h_1), \mathcal{P}^{(\lambda)})]. \quad (5.15) \]

**Proof of Theorems 2.12 and 2.13** Proof of the convergence of the normalized expectation and variance. The proofs of Theorems 2.12 and 2.13 go along the same lines as the proofs of Theorems 2.10 and 2.11: after application of Mecke’s formula and a suitable change of variables in the integral, we need to apply Lebesgue’s dominated convergence theorem which requires the convergence of formula and a suitable change of variables in the integral, we need to apply The proofs of Theorems 2.12 and 2.13 go along the same conation and variance.

As an example, we explain how to adapt Proposition 3.6, Lemma 4.1 and Proposition 4.3 to get the convergence of the expectation of \( \xi_{V,n,k}^{(\lambda)} \).

We claim that as soon as \( H_{\lambda}^{(\lambda)}((0, h_0), \mathcal{P}^{(\lambda)}) \leq \frac{r^2}{32} \), the calculation of \( \xi_{V,n,k}^{(\lambda)} \) only depends on the set \( \mathcal{U} \) defined at (3.39). Consequently, the radius of stabilization for \( \xi_{V,n,k}^{(\lambda)}((0, h), \mathcal{P}^{(\lambda)}) \) is the same as the one considered in Proposition 3.6.

To prove the moment bounds for \( \xi_{V,n,k}^{(\lambda)} \), we notice that \( \xi_{V,n,k}^{(\lambda)}(0, h) \) is smaller than the volume of \( C^{\leq H}(R) \) where \( R \) is the stabilization radius of \( \xi_{V,n,k}^{(\lambda)}((0, h), \mathcal{P}^{(\lambda)}) \) and \( H = H_{\lambda}^{(\lambda)}((0, h), \mathcal{P}^{(\lambda)}) \). Using Lemmas 3.5 and 3.6 as in the proof of Lemma 4.1, we deduce that for some \( c_1, c_2 > 0 \),

\[ \mathbb{E}[\xi_{V,n,k}^{(\lambda)}((0, h), \mathcal{P}^{(\lambda)})^p] \leq c_1 h^p \exp(-c_2 h^{d+1 \over 2}). \]

These two ingredients allow us to prove the convergence of \( \mathbb{E}[\xi_{V,n,k}^{(\lambda)}(w, \mathcal{P}^{(\lambda)})] \) with the help of the continuous mapping theorem as in Lemmas 4.2 and 4.3.

**Proof of the positivity of the limiting constants for the intrinsic volumes.** The defect intrinsic volumes are increasing with respect to set inclusion. As the limiting constant is positive for \( \text{conv}_1(\mathcal{P}^{(\lambda)}) \) [1, Theorem 3], it remains true for \( \text{conv}_n(\mathcal{P}_\lambda) \).

It remains to prove that the limiting constant for the variance is positive. The strategy is the same as the one that we used in the case of the k-faces. Because of the renormalization by \( \lambda \) in the definition of \( \xi_{V,n,k}^{(\lambda)} \), see (5.13), the equality (5.6) in the case of the volume scores becomes

\[ \lim_{\lambda \to \infty} \lambda^{d+3 \over 2d+7} \text{Var}[V_{n,k,\lambda}] = \lim_{\lambda \to \infty} \lambda^{-d+1 \over 2d+7} \text{Var}[	ilde{V}_{n,k,\lambda}], \]

where \( \tilde{V}_{n,k,\lambda} := \sum_{w \in \mathcal{P} \cap \mathcal{W}_\lambda} \xi_{V,n,k}^{(\infty)}(w, \mathcal{P}) \). The paragraph right after (5.6) details the rest of our strategy. We repeat word for word the first two steps of the proof of the positivity of the limiting variance on page 39, save for all the statements regarding \( F_{n,k} \). In the sequel we use the notations of the aforementioned proof and go directly to Step 3, i.e. the choice of the good configurations.
We discretize $W_\lambda$ by decomposing it into parallelepipeds and isolate the good parallelepipeds from the discretization as we have done for the $k$-faces. We choose $\delta$ and $\varepsilon$ which satisfy (5.7) with the choice $\rho = 1$. We take a large positive number $M$ and we partition $\left[-\frac{\lambda}{M} \frac{\pi_T}{2}, \frac{\lambda}{M} \frac{\pi_T}{2}\right]^{d-1}$ into $L := \left[\frac{\lambda}{M} \frac{\pi_T}{2}\right]^{d-1}$ cubes $Q_1, \ldots, Q_L$. We consider the cubes $Q_i$ satisfying the following properties, note that the main difference is the content of conditions b)1) and b)2):

(a) For each $z \in (\mathbb{Z}^{d-1} \cap \left(Q_i^{(\varepsilon)}\right) \times \{\delta\}, \mathcal{P} \cap B(z, \varepsilon)$ is a singleton and is put on the $n$-th layer using the tree construction associated with $\mathcal{T}_{n,1}$ and the perturbation of each point by at most $\varepsilon$ as in Step 1.

(b) One of these two conditions holds:

1. For each $z \in (\mathbb{Z}^{d-1} \cap \left(Q_i^{(\varepsilon)}\right) \times \{\delta\}, \mathcal{P} \cap B(z, \varepsilon)$ is a singleton and this point is put on the $n$-th layer in property (a).

2. For each $z \in (\mathbb{Z}^{d-1} \cap \left(Q_i^{(\varepsilon)}\right) \times \{\delta/2\}, \mathcal{P} \cap B(z, \varepsilon)$ is a singleton and this point is put on the $n$-th layer as before.

(c) Aside from the points described above, $\mathcal{P}$ has no point in $Q_i \times [0, \alpha]$.

After a possible relabeling, let $I := \{1, \ldots, K\}$ be the indices of cubes partitioning $\left[-\frac{\lambda}{M} \frac{\pi_T}{2}, \frac{\lambda}{M} \frac{\pi_T}{2}\right]^{d-1}$ that verify properties (a) to (c) and it remains true that

$$\mathbb{E}[K] \geq c \lambda^{\frac{d-1}{\pi_T}}. \quad (5.16)$$

Let $\mathcal{F}_\lambda$ be the $\sigma$-algebra generated by $I$, the positions of points in $W_\lambda \setminus (\bigcup_{i \in I} Q_i^{(\varepsilon)} \times [0, \alpha])$ and the scores $\hat{\xi}_{V, n, k}^{(\infty)}(x, \mathcal{P})$ at these points. For each $i \in I$ we claim that

$$\text{Var} \left[ \sum_{x \in \mathcal{P} \cap (Q_i \times [0, \alpha])} \xi_{V, n, k}^{(\infty)}(x, \mathcal{P}) \Big| \mathcal{F}_\lambda \right] = \text{Var} \left[ \sum_{x \in \mathcal{P} \cap (Q_i^{(\varepsilon)} \times [0, \alpha])} \xi_{V, n, k}^{(\infty)}(x, \mathcal{P}) \Big| \mathcal{F}_\lambda \right] \geq c_0. \quad (5.17)$$

Again, either condition (b1) or condition (b2) occurs in $Q_i^{(\varepsilon)} \times [0, \alpha]$, each with positive probability. To ensure that the remaining part of the proof for the $k$-faces works here as well, it remains to prove that $\sum_{x \in \mathcal{P} \cap (Q_i \times [0, \alpha])} \xi_{V, n, k}^{(\infty)}(x, \mathcal{P})$ is larger when (b1) is satisfied. We do it when $k = d$, i.e. in the case of the volume, as it contains all the ingredients needed to prove it for any intrinsic volume but with slightly less technicality that would only obfuscate the ideas.

If each point $z$ were deterministic in $(\mathbb{Z}^{d-1} \cap Q_i^{(\varepsilon)} \times \{\delta\} \text{ or } (\mathbb{Z}^{d-1} \cap Q_i^{(\varepsilon)} \times \{\delta/2\}$ then the $n$-th layer in case (b2) would be a copy of the $n$-th layer in case (b1) at a lower height. The difference of volume between the two cases (b1) and (b2) would thus be a constant times the difference of height, i.e. $c\delta$. In the general case when the points are random, since we can choose $\varepsilon > 0$ as small as we want, we can make the difference of volume as close as needed to this deterministic situation. Thus we can make sure.
that there exists a constant $c > 0$ such that $\sum_{x \in \mathcal{P} \cap (Q_i \times [0, \alpha])} \xi_{n,k}^{(\infty)}(x, \mathcal{P})$ in situation (b2) is smaller than $c$ times $\sum_{x \in \mathcal{P} \cap (Q_i \times [0, \alpha])} \xi_{n,k}^{(\infty)}(x, \mathcal{P})$ in situation (b1). Thus we have proved (5.17).

The end of the proof follows along the same lines as in the case of the $k$-faces.

\[ \square \]

6 Concluding remarks

Let us conclude with a list of possible extensions of our results and related open problems.

– Other intensity measures. In [15], the convex hull of a Poisson point process with a Gaussian intensity measure is studied. While the intensity of the process and therefore the rescaling are different, the techniques that are used are very similar so these results should extend to the $n$-th layer as we did in this paper for the uniform measure in the unit ball. We also expect that our results extend to a stationary Poisson point process in any smooth convex body as in [14] where the case of the first layer is treated. The $n$-th layer should have the same behaviour as the first one in this case as well. However, [14] uses a sandwiching result stating that with high probability the first layer lies between two floating bodies, see [30]. Such a result has not been proved for the $n$-th layer and would be interesting on its own.

The same kind of problem arises in [16] about the convex hull of the peeling of a uniform point set in a polytope. Again, an argument on the sandwiching of the first layer is needed, see [6]. An extension to the $n$-th layer inside a polytope will be the subject of a future work.

Finally, in [4] asymptotic results on the expected number of vertices of the convex hull of an i.i.d. sample of an arbitrary non atomic probability distribution on $\mathbb{R}^d$ are derived from an approximation of the convex hull with floating bodies. We may hope that an approximation of the same kind should be possible for the $n$-th layer.

– Invariance principles. Let us consider the processes defined as the integrated versions of the defect support function and radius support function of each of the first layers. It is proved in [13, Theorem 8.3] that in the case of the first layer, such processes when properly rescaled and centered converge to a Brownian sheet process. We expect to get analogous functional central limit theorems for subsequent layers as we think that the arguments, for both the convergence of the finite-dimensional distributions and the tightness, should translate well to the case of the $n$-th layer. This would certainly be more challenging to do so when the number of the layer depends on $\lambda$, see below.

– Depoissonization. We left aside the case where we have a fixed number of i.i.d. random points uniformly distributed in the unit ball, i.e. a binomial point process instead of a Poisson point process. We expect a result of depoissonization in the spirit of [14, Theorem 1.2] and [17, Theorem 1.1] to occur.
Optimal Berry-Esseen bounds. Recently, a method to derive central limit theorems for stabilizing functionals has been derived in [28]. The case of the number of $k$-faces of a convex hull of Poisson point processes in a smooth convex body is given as an application with an improved rate of convergence, i.e. $O\left(\lambda^{-\frac{d-1}{2(d+1)}}\right)$ instead of $O\left(\lambda^{-\frac{d-1}{2d+1}} \left(\log \lambda\right)^{d+1}\right)$ as in Theorem 1.1. We conjecture that the same rate of convergence should hold for the $n$-th layer but extending the method from [28, Theorem 3.5] seems somehow challenging.

Monotonicity. A monotonicity problem arises naturally from Theorem 1.1. Denoting by $C_{n,k,d}$ the limit obtained for the expectation in Theorem 1.1, we might wonder how the constants $C_{n,0,d}$ evolve with $n$. For $k = 0$, we expect that the sequence $(C_{n,0,d})_n$ decreases with $n$. This is what our simulations suggest. In general, monotonicity problems in random polytopes are difficult. For instance, it has been justified that in most cases, the mean volume of the convex hull of a uniform point set in a convex body $K$ is not a monotone function of $K$ with respect to set inclusion, see [29] and [27]. Nevertheless, some insightful results on the monotonicity of the number of $k$-faces of the convex hull when the number of points increases can be found in [21], [8] and [10].

Other regimes. Until now we have only considered a fixed layer number $n$ that does not depend $\lambda$ which means that we have only studied the first layers. It would be interesting to study different regimes, where $n$ would vary with $\lambda$. Thanks to [20] and [12] we know that the expected number of layers is equivalent to $\lambda^{\frac{1}{2d+1}}$ up to a constant. Thus a natural regime to study would be the case where $n = c\lambda^{\frac{1}{2d+1}}$. Calder and Smart conjecture in [12] that the mean number of points in this regime is still equivalent to $\lambda^{\frac{1}{2d+1}}$ up to an explicit constant. They provide in particular a heuristic argument and simulations that we were able to reproduce.
