BRIEF REPORT

Smoking cessation in primary care: Implementation of a proactive telephone intervention

Abstract

Purpose: To perform a smoking cessation intervention by a nurse practitioner in a primary care setting and assess its effectiveness.

Data sources: The intervention developed was an operationalization of the five As from the U.S. Department of Health and Human Services’ updated Clinical Practice Guideline: Treating Tobacco Use and Dependence. Data were generated from a two-group controlled intervention that compared adult smokers who either received or did not receive an intensive proactive telephone intervention focused on cessation.

Conclusions: The intervention group showed movement across the stages of change, lower nicotine dependence, and increased confidence to quit. Also, 19% quit smoking and were abstinent at the end of study; none in the control group achieved abstinence. Quit rates were similar to those of other studies. The statistically necessary sample size was not attained, highlighting recruitment difficulties in smoking cessation studies. For a pilot study, the sample size was acceptable.

Implications for practice: Measuring stage of change and nicotine dependence can assist clinicians in implementing cessation strategies. Although effective, a provider may find the intervention too intensive to employ with more than one patient at a time. This intervention should be evaluated with smokers ready to make a quit attempt.

Introduction

Despite detrimental health effects of smoking and the existence of effective cessation strategies, health professionals are hesitant to discuss smoking cessation because of insufficient time, concern about offending patients, and low confidence in delivering an effective message (Garg et al., 2007; Tong, Strouse, Hall, Kovac, & Schroeder, 2010). Clinicians assess smoking status but are not comfortable implementing cessation and do not consistently utilize proven guidelines (Fiore et al., 2008; Tong et al., 2010).

The 2008 updated Clinical Practice Guideline for Tobacco Cessation recommends undertaking research to evaluate cessation interventions given by nurse practitioners (NPs), readiness to change, using the telephone as an intervention, and implementing the five As (Ask about smoking; Advise the patient to quit in a strong, clear, and personalized manner; Assess willingness to attempt quitting; Assist in making a quit attempt, offering support if willing; and Arrange follow-up contact the week after the quit date; Fiore et al., 2008).

The 2008 Clinical Practice Guideline recommends intensive proactive telephone counseling, problem solving, and support as effective cessation strategies (Fiore et al., 2008). Telephone interventions applied in a variety of health-related situations increased quit rates and were acceptable to patients (Stead, Perera, & Lancaster, 2009; Tzelepis, Paul, Walsh, McElduff, & Knight, 2011). is described an evaluation of a proactive telephone intervention that was developed using the five As.

This study took place over a 3-month period and entailed maintaining contact with adult smokers, focusing on whether or not the intervention moved smokers along the stages of change, increased smoking cessation, and increased quit attempts. Two groups were compared (a control and an intervention group) and incorporated the idea that smoking cessation involves two distinct processes: making a quit attempt and maintaining cessation (Brunnhuber, Cummings, Feit, Sherman, & Woodcock, 2007). The transtheoretical model was the theoretical basis for the study, postulating that behavior change occurs as a nonlinear process, in a series of stages, over time (Prochaska, Wright, & Velicer, 2008). Two constructs central to this model are decisional balance (weighting benefits and costs of changing behavior) and self-efficacy (confidence in ability to change). There are five transtheoretical stages as follows: precontemplation (no plan to quit in the next 6 months), contemplation (seriously thinking about quitting in the next 6 months or no prior quit attempt and decided to quit in next 30 days), preparation (prior quit attempt in past 12 months and decided to quit in next 30 days), action (quit smoking less than 6 months ago), and maintenance (quit smoking greater than 6 months ago; Prochaska et al., 2008).

The research question

Are adult patients who smoke more likely to move through the stages of change toward an attempt at smoking cessation when they receive an intensive proactive telephone intervention and written cessation materials in comparison to receiving written cessation materials alone?

Methods

Study population

The study population participated in a previous study of adult smokers (n = 169). A power analysis was performed (α < .05, β = .80) with effect size of 0.30 (medium effect), yielding that a sample size of 90 would sufficiently power the study. The participant recruitment target was set at 100 to account for attrition. However, this proved to be an unattainable goal despite participants having agreed to participate in the prior study that included a telephone call. This underscores the challenge in recruiting willing participants in smoking cessation research. This size was acceptable for a pilot study.

Study design

This was a two-group controlled intervention pilot study with blinded group assignment. This pilot study compared an evidence-based telephone intervention plus printed smoking cessation guide (intervention group) to printed smoking cessation guide alone (control group) (U.S. Department of Health and Human Services, 2006). Human subject approval was received from the University of Illinois at Chicago College of Medicine at Rockford’s IRB.

Initial contact with subjects was made through the mail. All subjects received an introductory letter explaining the study; smoking cessation guide; consent form; and an addressed, stamped envelope. Two weeks after the initial contact, the primary investigator (PI), an NP, attempted telephone contact with all of the target population to ascertain willingness to participate. People were asked to sign and return the consent form that had to be received before beginning the intervention.

Intervention

TheTelephone Intervention Guide, implemented by the PI, was drawn from the five As (Fiore et al., 2008). Three members of the 2008 Clinical Practice Guideline Panel established content and face validity. The intervention focused on engaging the study participant in reflecting on reasons for smoking, harms inherent in continuing to smoke, challenges faced in quitting, and the choice that each cigarette presents of quitting or continuing to smoke. The telephone intervention was delivered by four telephone calls (baseline, 4, 8, and 12 weeks), while the control group received two calls (baseline and 12 weeks) where smoking status and stage of change were measured. For those who elected to make a quit attempt, problem solving and social support were offered as part of the continued intervention. Social support was operationalized as daily text messaging or telephone calls during the week of the quit attempt.

Outcome measures

The primary outcome measures were stage of change and smoking cessation. Secondary outcome measures included quit attempts, self-rating of confidence and motivation to quit, and change in Heaviness of Smoking Index (HSI; Borland, Yong, O’Connor, Hyland, & Thompson, 2010). Smoking cessation was defined as continuous abstinence for more than 7 days and a quit attempt was defined as 24-h abstinence (Sutton & Gilbert, 2007).
Table 1  Open-ended questions asked of intervention participants at each call

1. What do you think helped you quit smoking the last time?
2. What do you think got you started smoking again?
3. Do you currently have any health concerns related to your smoking?
4. If yes, what are some of your health concerns related to your smoking?
5. What do you like about your smoking?
6. What don’t you like about your smoking?
7. How do you think quitting might help you?
8. What will be hard about quitting?

Measurement tools

Three measurement tools were used in the study. The HSI measures nicotine dependence and includes daily cigarette consumption and time to first cigarette (≤2 = low; 2–4 = medium; 5–6 = high nicotine dependence; Borland et al., 2010). Stages of change survey measure the current stage of and readiness to change (Wolf et al., 2008). Motivational and self-efficacy scales measure motivation and confidence in quitting on a scale of 1–10 determined by answers given to two questions: On a scale of 1 (low) to 10 (high), how motivated are you to quit and how confident are you that you would succeed (Halterman, Borrelli, Conn, Tremblay, & Blaakman, 2010)? Additionally, open-ended questions were asked to encourage problem solving (Table 1) as recommended by the Guideline (Fiore et al., 2008).

Table 2  Description of study participants by group assignment

| Variables and Factors       | Control N (%) | Intervention N (%) |
|-----------------------------|---------------|--------------------|
| Gender                      |               |                    |
| Female                      | 10 (55.6%)    | 19 (90.5%)         |
| Male                        | 8 (44.4%)     | 2 (9.5%)           |
| Age                         |               |                    |
| 50 and younger              | 9 (50.0%)     | 11 (52.4%)         |
| Older than 50               | 9 (50.0%)     | 10 (47.6%)         |
| Self-defined health status  |               |                    |
| Excellent to very good health | 5 (27.8%)   | 6 (28.6%)          |
| Good to fair health         | 13 (72.2%)    | 15 (71.4%)         |
| Partner status              |               |                    |
| Partnered                   | 13 (72.2%)    | 12 (57.1%)         |
| Not partnered               | 5 (27.8%)     | 9 (42.9%)          |
| Education                   |               |                    |
| At least high school        | 12 (66.7%)    | 14 (66.7%)         |
| More than high school       | 6 (33.3%)     | 7 (33.3%)          |
| Annual household income     |               |                    |
| $39,999 or less             | 11 (61.1%)    | 9 (42.9%)          |
| $40,000 or more             | 7 (38.9%)     | 12 (57.1%)         |

Table 3  Smoking history of control and intervention study participants

| Variables Factors | Control N (%) | Intervention N (%) |
|-------------------|---------------|--------------------|
| How long smoked   |               |                    |
| ≤20 years         | 4 (22.2%)     | 6 (28.6%)          |
| >20 years         | 14 (77.8%)    | 15 (71.4%)         |
| Ever tried quitting |             |                    |
| Yes               | 18 (100.0%)   | 21 (100.0%)        |
| Longest time quit |               |                    |
| <6 months         | 6 (33.3%)     | 8 (38.1%)          |
| ≥6 months         | 12 (66.7%)    | 13 (61.9%)         |
| Last quit attempt |               |                    |
| <6 months ago     | 4 (22.2%)     | 1 (4.8%)           |
| ≥6 months ago     | 14 (77.8%)    | 20 (95.2%)         |

Results

Data were analyzed descriptively due to small sample size. Out of a possible 169 participants, 72 were not reachable. Thirty-nine people agreed to participate and were randomly assigned to intervention (21) and control (18) groups (Table 2) for a 40.0% participation rate. Table 2 describes the study participants by group assignment (intervention or control) and covariates (sex, age, self-defined health status, partner status, education, and annual household income).

Smoking history (Table 3) revealed a larger proportion of both groups had been smokers for >20 years. Everyone had tried to quit smoking at least once. For the majority of both groups, the longest quit attempt was ≥6 months with the last quit attempt made six or more months ago.

At call one, 19% of the intervention group was highly nicotine-dependent; by call four, none of the intervention group described themselves as highly nicotine-dependent (Table 4). Among controls, there was an increase in those who described themselves as low nicotine-dependent between calls one and four.

There was movement across all stages of change in the intervention group between the first and last telephone call (Table 4). At the time of the initial call, 38.1% of the intervention group was in the precontemplation stage, which decreased to 19.0% by the final call. For the intervention group at call one, 52.4% were in the contemplation stage, while at call four this had been reduced to 42.9%. Further, those in the preparation stage increased from 9.5% to 14.3% by the last call. Finally, none of the intervention participants were in the action stage at call one, while 19.0% were in the action stage at call four.

Among controls, the same proportion stayed in the maintenance stage across all phone calls.

A Likert scale was used to assess motivation and confidence giving up smoking (1 = not at all motivated or confident and 10 = 100% motivated and confident; Table 5). The responses were recoded into bifurcated categories, with seven or below recoded as “less motivated to quit” and
### Table 4 Comparison between Call 1 and Call 4 of nicotine dependence and stages of change by group status

| Measure             | Scale Items                  | Group Call 1 | Group Call 4 |

### Table 5 Comparison of intervention group motivation and confidence to quit by number of call

| Scale of Motivation | Motivated to Quit | Call 1 N (%) | More Motivated to Quit | Call 2 N (%) | Less Motivated to Quit | Call 3 N (%) | More Motivated to Quit | Call 4 N (%) | Less Motivated to Quit | Call 4 N (%) |
|---------------------|-------------------|--------------|-------------------------|--------------|-------------------------|--------------|-------------------------|--------------|-------------------------|--------------|
| N                   | 14                | 66.7         | 7                       | 33.3         | 16                      | 88.9         | 2                       | 11.1         | 14                      | 87.5         |
| Confidence Scale    | N                 | N            | N                       | N            | N                       | N            | N                       | N            | N                       | N            |

### Table 6 Comparison of quitters by initial and final call

| Variables and Factors | First Call N (%) | Final Call N (%) |
|-----------------------|------------------|------------------|
| HSI score             | 1 (25)           | 4 (100)          |
| Medium nicotine       | 3 (75)           |                  |
| Contemplation         | 2 (50)           | 4 (100)          |
| Preparation           | 2 (50)           | 2 (50)           |
| Action                |                  |                  |
| More confidence in quitting | 1 (25) | 2 (50) |
| Less confidence in quitting | 3 (75) | 2 (50) |
| More motivated to quit | 3 (75) | 4 (100) |
| Less motivated to quit | 1 (25) |            |

Eight or above recoded as “more motivated to quit.” The confidence scale was similarly recoded.

The motivation and confidence responses indicated that one third of the group was more motivated to quit at call one, and by call four, only one fourth of the group was more motivated to quit. However, four people quit smoking between calls one and four (Table 8). There was an increase in confidence, with 28.6% of the participants gave a number that reflected more confidence at call one and over 50% of the participants gave a number that reflected more confidence in quitting at call four.

The study participants were asked a number of the problem-solving questions for generating coding themes (Table 7). Four themes emerged from the reasons given for smoking relapse, which are as follows: coping with stress, craving, exposure to smoker, and weight control. The majority of respondents from both the groups gave reasons that corresponded with the theme “coping with stress” to describe their smoking relapse. Health concerns, such as breathing problems, were acknowledged by 50.0% of the control group, while 33.3% of the intervention group cited diagnosed disease. A small proportion of each group (22.2% control, 23.8% intervention) stated that they had no health concerns.

When describing what they liked about smoking, the control group in almost equal proportions stated habit (38.9%), stress relief (33.3%), and nothing (27.8%), while the majority of the intervention group (57.1%) cited stress relief. Further, the cost of addiction was reported by over half of the control group as what they most disliked about smoking. In contrast, the largest proportion of the intervention group cited polluting personal environment as what they disliked most about their smoking.
Improving one’s health and personal environment was given as the greatest benefit of quitting by the majority of participants in both groups. A small proportion of participants in each group saw no benefit to smoking cessation. For the majority in each group, the greatest challenge of quitting was finding a substitute.

Quitters

Four intervention group participants (19.0%) quit smoking over the course of this intervention study (Table 8). Length of cessation ranged from 2.5 to 10 weeks of continuous cessation. All of the quitters were female. Three of the four quitters were 50 years of age or younger. When self-describing their health, half said they were in excellent to very good health, while the other half reporting good to fair health. One was single, and the others were part of couples. The highest educational attainment for all quitters was high school or less. All but one lived in households with incomes of $40,000 or more.

Study participants who quit were more likely to cite an external event as the factor that helped them quit smoking in the past (Table 9). Likewise, they were more likely to claim stress as the reason for past relapse. All but one of the quitters stated that they had health concerns related to smoking. At the time of the initial call, three of the quitters stated that polluting their personal environment was what they disliked most about smoking. Not surprisingly, improving one’s health and environment was offered as the main benefit of quitting. Finally,

Table 7 Coding themes for qualitative data

| Variables                              | Factors                     | Control N (%) | Intervention N (%) |
|----------------------------------------|-----------------------------|---------------|--------------------|
| Help quit smoking code                 | External event              | 7 (38.9)      | 11 (52.4)          |
|                                        | Internal decision           | 6 (33.3)      | 6 (28.6)           |
|                                        | Prescription medication     | 5 (27.8)      | 4 (19.0)           |
| Smoking relapse code                   | Coping with stress          | 10 (55.6)     | 13 (61.9)          |
|                                        | Craving                     | 3 (16.7)      | 3 (14.3)           |
|                                        | Exposure to smoker          | 4 (22.2)      | 4 (19.0)           |
|                                        | Weight control              | 1 (5.6)       | 1 (4.8)            |
| Have health concerns related to smoking| No                          | 4 (22.2)      | 5 (23.8)           |
|                                        | Yes                         | 14 (77.8)     | 16 (76.2)          |
| Health concerns code                   | Breathing problems          | 9 (50.0)      | 4 (19.0)           |
|                                        | Diagnosed disease           | 4 (22.2)      | 7 (33.3)           |
|                                        | Family history of cancer    | 0 (0.0)       | 2 (9.5)            |
|                                        | Know smoking bad            | 2 (11.1)      | 4 (19.0)           |
|                                        | None                        | 3 (16.7)      | 4 (19.0)           |

Table 8 Description of quitters

| Variables and Factors | Frequency | Percent |
|-----------------------|-----------|---------|
| Gender                | Female    | 4       | 100.0   |
| Age                   | 50 and younger | 3 | 75.0   |
|                       | Older than 50 | 1 | 25.0   |
| Self-defined health   | Excellent to very good health | 2 | 50.0   |
|                       | Good to fair health | 2 | 50.0   |
| Partner status        | Coupled   | 3       | 75.0   |
|                       | Single    | 1       | 25.0   |
| Education             | High school or less | 4 | 100.0   |
| Household income      | $39,999 or less | 1 | 25.0   |
|                       | $40,000 or more | 3 | 75.0   |
Table 9 Coding themes for qualitative data for quitters for Call 1

| Variables and Factors | Frequency | Percent |
|-----------------------|-----------|---------|
| Help quit smoking code | External event | 3 | 75.0 |
| Prescription medication | 1 | 25.0 |
| Smoking relapse code | Coping with stress | 3 | 75.0 |
| Exposure to smoker | 1 | 25.0 |
| Have health concerns related to smoking | No | 1 | 25.0 |
| Yes | 3 | 75.0 |
| Health concerns code | Breathing problems | 1 | 25.0 |
| None | 1 | 25.0 |
| Diagnosed disease | 2 | 50.0 |
| Like about smoking code | Habit | 1 | 25.0 |
| Nothing | 1 | 25.0 |
| Stress relief | 2 | 50.0 |
| Dislike about smoking code | Cost of addiction | 1 | 25.0 |
| Polluting personal environment | 3 | 75.0 |
| Benefits of quitting code | Improve health and environment | 4 | 100.0 |
| Challenges of quitting | Finding a substitute | 2 | 50.0 |
| Handling temptation | 2 | 50.0 |

Finding a substitution and handling temptation were cited equally as challenges of quitting.

In contrast to the initial call, during the final call to study participants who had quit, one cited improving personal environment as a benefit of quitting, while the other three cited health improvement as the benefit (data not shown). In addition, the study participants who quit articulated their strategies for dealing with cravings as doing something else, such as playing computer games, or tricking themselves by saying “you have just had one” (data not shown).

When comparing the initial and final call to quitters, three of the four quitters had medium nicotine dependence initially, while all four had low nicotine dependence at the final call. Furthermore, all quitters were in the action stage at the final call, having moved from contemplation and preparation at the initial call. Finally, at the last call made to participants who had quit, all were more motivated to stay smoke-free.

There were a total of seven quit attempts made by five other study participants in the intervention group. These attempts lasted from 1 day to 3 weeks. At the time of the final call, these five participants were smoking, having relapsed from a quit attempt during the intervening time. For the intervention group, 18 total quit attempts were made for a cessation rate of 86%. A member of the control group made one 24-h quit attempt.

Discussion

A number of tools measured different dimensions of smokers’ experiences and relationships with smoking tobacco, yielding five important findings.

The first important finding was that when measuring readiness to quit with a stage of change survey, there was movement across all stages of change in the intervention group. This movement was less pronounced in the control group, suggesting that the intensive phone intervention encouraged those smokers to move toward a quit attempt. For primary care providers, assessing patients’ readiness to change is essential and initiates conversation about smoking cessation between provider and patient. Use of a survey of this nature can be a springboard to assist providers to overcome the discomfort of approaching patients about their smoking (Garg et al., 2007).

The second important finding was that when measuring nicotine dependence by self-report, there was less dependence at the end of the intervention for those in the intervention group. The HSI (Borland et al., 2010) is another tool for primary care providers to use in their assessment of patients who want to quit. Using this measure would help differentiate between physical and psychological addiction. Prolonged abstinence from smoking depends on breaking the psychological or behavioral habituation. Study participants cited finding a substitute and handling temptation as among their challenges in quitting smoking. Hence, measuring nicotine dependence on an ongoing basis, as people are moving toward smoking abstinence, may provide important direction to providers as they develop individually focused cessation strategies.

The third important finding was that the intervention group demonstrated an increase in confidence to quit smoking over the course of the study. This did not occur for the control group. This suggests that the intervention positively affected the level of confidence of the intervention participants regarding quitting smoking. Because each cessation attempt increases momentum for abstinence, measuring confidence for smoking cessation is an accepted and endorsed component in the treatment of tobacco dependence (Fiore et al., 2008).

The fourth important finding was that the majority of study participants reported having health concerns related to their smoking and acknowledged benefits to quitting. This finding is consistent with research that demonstrates smoking is negatively associated with health-related quality of life (Vogl, Wenig, Leidl, & Pokhrel, 2012).
Finally, 19% of the intervention group quit smoking and were abstinent at the end of the study; this was not true for any of the participants in the control group. This rate is well within the quit rates documented by other studies (Nayan, Gupta, & Sommer, 2011). Furthermore, intervention participants, with an 86% cessation rate, made 18 total quit attempts. These findings support the chronic nature of cigarette smoking and the difficulty of quitting.

Limitations

There were three limitations to this study. First, by limiting the target population to participants in a former smoking cessation study, this study was at risk for having a small sample size. As a result, the study was underpowered and could not use analytic statistics.

Second, the intensity of the intervention was in itself a limitation. Operationalizing the components of the Smoking Cessation Guideline was cumbersome. As a result, the intervention, beyond being intense, required too much time to implement for it to be of practical use in a primary care setting. This is not to suggest that the theoretical concepts individually are not robust, only that when operationalized in the fashion that they were for this intervention, the application was not realistic. No single primary care provider would be able to implement this intervention for more than one patient at a time. Nevertheless, this limitation could not have been revealed without conducting this study. Thus, the study contributes an important thread to the ongoing conversation about time resources in smoking cessation interventions.

Third, the PI for this study managed the intervention for all of the participants as if she was their primary care provider. However, she was not the true primary care provider; thus, the foundational relationship inherent to primary care was absent from this intervention study. This could have impacted the results because of the immediate and temporary nature of the relationship.

Conclusions

This smoking cessation intervention study undertaken by a NP evaluated the effectiveness of advice to quit smoking by a provider other than a physician. In this study, there were people who quit as well as who attempted to quit smoking. The intervention group showed movement across stages of change, lower nicotine dependence, and increased confidence to quit. The quit rates were similar to those of other studies. Research has demonstrated that relapse is both part of the nature of smoking as well as a contributing factor to permanent abstinence. There is value to evaluating this intervention with smokers farther along the stages of change.
