July 20, 2016

Abstract

This paper considers quantile model with grouped explanatory variables. In order to have the sparsity of the parameter groups but also the sparsity between two successive groups of variables, we propose and study an adaptive fused group LASSO quantile estimator. The number of variable groups can be fixed or divergent. We find the convergence rate under classical assumptions and we show that the proposed estimator satisfies the oracle properties.

Keywords: group selection; quantile regression; adaptive fused LASSO; selection consistency; oracle properties.

1 Introduction

The idea of this paper comes from the ascertainment that in many practical applications, for studying a process or a random variable in function of grouped explanatory variables, we want to identify significant groups of variables but also to make a hierarchy between these groups. The explanatory variables can be continuous or discrete. The most common example of linear model with grouped variables is the multivariate variance analysis. But in many situations for theoretical study of the linear models, classical assumptions are imposed on errors: zero mean and bounded variance, which is not often the case in applications. Then, if these classical assumptions are not satisfied or if the model has heavy-tailed errors, a very interesting approach is the quantile method. Moreover, compared to classical estimation methods (least squares, least absolute deviations) which give the model behaviour around of the mean or of the median, the quantile method offers a very complex and global insight. This method allows to study how the explanatory variables influence the response variable distribution. For a complete overview on quantile method, we refer the reader to book of Koenker (2005). Then, in order to cover more possible cases of models, in this paper, we will consider grouped quantile regression, which allows the relaxation of the classical conditions on the two first moments of the model error. We also want to identify the relevant variable groups, an automatic selection by a LASSO type method of the significant variable groups being more meaningful than an automatic selection of individual variables. The LASSO estimator, introduced by Tibshirani (1996) for the least squares framework, doesn’t always satisfy the automatic selection, and then a solution is the adaptive LASSO estimator, proposed initially by Zou (2006).

The LASSO methods have been the subject of active research in the last decade. We give here only the references concerning the LASSO methods for models with grouped variables. Zhang and Xiang (2015), Ciuperca (2016a) have considered the adaptive group LASSO in high-dimensional linear model by penalizing the sum of squares, respectively quantile process. Earlier, Wei and Huang (2010) had considered the adaptive group LASSO estimator but for gaussian model error. Wang et al (2015) study also the convergence and the sparsity of the (non adaptive) group LASSO estimator in a high-dimensional generalized linear model. When the number of groups is fixed, Wang and Leng
Adaptive Fused LASSO in Grouped Quantile Regression

(2008) show the model consistency obtained by an adaptive group LASSO method. For a review, but until 2012, of group selection methods and several applications of these methods the reader can see Huang et al. (2012).

For a linear model, without grouped variables, in order to encourage sparsity of the parameters but also the sparsity of their differences, to identify predictive variable clusters, Tibshirani et al. (2005) introduced an additional penalty to the LASSO penalty, taking the $L_1$ norm of the differences between two successive parameters. They called the obtained estimator, fused LASSO estimator. Applications of the fused LASSO method can be found in Jang et al. (2015) or in Li and Zhu (2007). The fused LASSO idea was adopted by Jiang et al. (2013, 2014), Zhao et al. (2014) for quantile model. A very recent paper of Viallon et al. (2016), considers a generalized linear models, estimated by adaptive fused LASSO method. Adaptive fused LASSO penalty is also used by Sun et al. (2016) for estimation of the spatial and temporal quantile functions. These papers have in common that the models have fixed number of explanatory variables.

The fused LASSO penalty for grouped variables, proposed and studied in this paper, will be helpful to strengthen the sparsity between two successive groups of variables. To the knowledge of the author, the adaptive fused LASSO method wasn’t considered for a linear model and further, with the possibility that the number of groups converges to infinity when number of observations diverges. Even for quantile linear models without grouped variables, there is no work in literature on the adaptive fused LASSO method. This is the originality of the present paper. Emphasize that the proposed estimator and obtained results are valid for a wide spectrum of error distributions.

The paper is organized as follows. In Section 2 we present the quantile model with grouped variables, we also introduce the adaptive fused estimator and we give general notations and assumptions. In Section 3 we study the convergence rate, oracle properties of the estimator when the group number is fixed. A general convergence rate when the group number diverges is found in Section 4. In the same section, we state that the oracle properties remain true. All proofs will be postponed in Section 5.

3
2 Model, notations and assumptions

In this section, we first introduce the quantile model with grouped variables. Afterwards, some notations used throughout in the paper are given, followed by the introduction of the proposed fused estimator. Finally, general assumptions on the model errors, design and on the group number are given.

Let us consider the following linear model with \( p \) groups of variables

\[
Y_i = \sum_{j=1}^{p} X_{ij}^t \beta_j + \varepsilon_i = X_i^t \beta + \varepsilon_i, \quad i = 1, \cdots, n. \tag{2.1}
\]

The random variables in model (2.1) are: \( Y_i \) the response variable and \( \varepsilon_i \) the model error. The column vector \( X_i \) is the \( i \)th observation of the explanatory variables and its contains \( p \) groups of variables. For each group \( j \), with \( j = 1, \cdots, p \), the vector of the parameters is \( \beta_j \equiv (\beta_{j1}, \cdots, \beta_{jd_j}) \in \mathbb{R}^{d_j} \) and the design \( X_{ij} \) for observation \( i \), is a vector of size \( d_j \times 1 \). The vector with all coefficients is \( \beta \equiv (\beta_1, \cdots, \beta_p) \) and \( \beta_j^0 \equiv (\beta_{j1}^0, \cdots, \beta_{jd_j}^0) \) the true (unknown) value of the parameter \( \beta_j \), for \( j = 1, \cdots, p \). For observation \( i \), we denote by \( X_{ij,k} \) the \( k \)th variable of the \( j \)th group. We will assume that \( d_j = d \) for any \( j = 1, \cdots, p \) by taking \( d = \max_{j=1,\cdots,p} d_j \), filling the components of \( \beta_j \) between \( d_j \) and \( d \) with 0 and the values of \( X_i \) also with 0.

For model (2.1) it is possible that there are insignificant variables groups. For this, we will consider the index set of the significant groups:

\[
\mathcal{A} \equiv \{ j \in \{1, \cdots, p\}; \|\beta_j^0\| \neq 0 \}
\]

and obviously the index set of the insignificant groups \( \mathcal{A}^c \equiv \{ j; \|\beta_j^0\| = 0 \} \). We denoted by \( |\mathcal{A}| \) the cardinal of the index set \( \mathcal{A} \). Obviously, in practical applications, the two sets \( \mathcal{A} \) and \( \mathcal{A}^c \) are unknown.

On the other hand, we denote by \( |\mathcal{A}| = p^0, \ r^0 = dp^0 \) and \( r = dp \). The numbers \( p \) and \( d \) are known, \( p^0 \) is contrariwise unknown and then \( r^0 \) also.

For a \( r \)-vector of parameters \( \beta \), we denote \( \beta_{\mathcal{A}} \) the subvector of \( \beta \), of dimension \( r^0 \times 1 \), which
contains $\beta_j$, for $j \in \mathcal{A}$. The $(r - r^0)$-vector $\beta_{\mathcal{A}^c}$ contains $\beta_j$ for $j \in \mathcal{A}^c$.

We introduce now the quantile model. This method allows the non necessity of the classical assumptions on errors: $E[\varepsilon_i] = 0$ and $\text{Var}(\varepsilon_i) < \infty$. Since these assumptions are not often satisfied in practical applications, the quantile method can be used extensively in many different areas.

So, for a quantile index $\tau \in (0, 1)$, the check function $\rho_\tau(.) : \mathbb{R} \to \mathbb{R}_+$ is defined by $\rho_\tau(u) = u(\tau - 11_{u<0})$. In this paper, the index $\tau$ is considered fixed.

Before defining the adapted fused LASSO estimator for the parameter $\beta$ of (2.1), we give some general notations. All throughout the paper, $C$ denotes a positive generic constant not dependent on $n$, which may take different values in different formula or even in different parts of the same formula. The value of $C$ is not of interest. All vectors and matrices are denoted by bold symbols and all vectors are written as column vectors. For a vector $v$, we denote by $v^t$ its transposed and by $\|v\|$ its Euclidean norm. Notations $\xrightarrow{n \to \infty}$, $\xrightarrow{p}$ represent the convergence in distribution and in probability, respectively, as $n \to \infty$. For a positive definite matrix $M$, we denote by $\lambda_{\text{min}}(M)$ and $\lambda_{\text{max}}(M)$ its the smallest and largest eigenvalues, respectively. When it is not specified, the convergence is for $n \to \infty$.

For model (2.1), $n$ observations of $(Y_i, X_i)_{1 \leq i \leq n}$ are available. In order to define the estimator that will allow automatic selection of significant groups of variables, we must first consider the quantile process:

$$G_n(\beta) \equiv \sum_{i=1}^{n} \rho_\tau(Y_i - X_i^t \beta).$$

The quantile estimator for $\beta$ is the minimizer of the quantile process:

$$\bar{\beta}_n \equiv \arg\min_{\beta \in \mathbb{R}^r} G_n(\beta). \quad (2.2)$$
This estimator can be written taking into account each group \( \tilde{\beta}_n = (\tilde{\beta}_{n;1}, \tilde{\beta}_{n;2}, \ldots, \tilde{\beta}_{n;p}) \), with \( \tilde{\beta}_{n;j} \) a vector of size \( d \), for \( j = 1, \ldots, p \). We will use \( \tilde{\beta}_n \) for constructing the two adaptive LASSO penalties. Note that, the number \( r \) of the total variables needs to be smaller than the sample size \( n \). For model (2.1), we define the adaptive fused group LASSO quantile (afgLASSO\(_Q\)) estimator, denoted by \( \hat{\beta}_n \), as the minimizer of the following process:

\[
Q_n(\beta) \equiv G_n(\beta) + \mu_n^{(1)} \sum_{j=1}^{p} \hat{\omega}^{(1)}_{n;j} \| \beta_j \| + \mu_n^{(2)} \sum_{j=2}^{p} \hat{\omega}^{(2)}_{n;j} \| \beta_j - \beta_{j-1} \|, \tag{2.3}
\]

with the weights \( \hat{\omega}^{(1)}_{n;j} \equiv \| \tilde{\beta}_{n;j} \|^{-\gamma} \), \( \hat{\omega}^{(2)}_{n;j} \equiv \| \tilde{\beta}_{n;j} - \tilde{\beta}_{n;j-1} \|^{-\gamma} \) and \( \gamma > 0 \) a fixed known parameter. The estimator \( \hat{\beta}_n \) is written \( \hat{\beta}_n = (\hat{\beta}_{n;1}, \ldots, \hat{\beta}_{n;p}) \) and \( \hat{\beta}_{n;j} \) is a vector of size \( d \), for \( j = 1, \ldots, p \). The tuning parameters \( \mu_n^{(1)}, \mu_n^{(2)} \) are assumed to converge to infinity as \( n \to \infty \). Additional conditions on \( \mu_n^{(1)}, \mu_n^{(2)} \), taking into account \( \gamma \) and the group number \( p \), will be given later.

The purpose of this paper is to study the properties of the estimator \( \hat{\beta}_n \), mainly the oracle properties: the significant groups of variables are estimated, with an optimal estimation rate, by asymptotically gaussian estimators and the corresponding parameters to nonsignificant groups are shrunk directly to 0 with a probability converging to one. In order to study the asymptotic properties of the afgLASSO\(_Q\) estimator \( \hat{\beta}_n \), for some \( r \)-vector \( \beta \in \mathbb{R}^r \), we also consider the process:

\[
L_n(\beta) \equiv Q_n(\beta) - Q_n(\beta^0). \tag{2.4}
\]

Let us note that, for \( \tau = 1/2 \), model (2.1) becomes median regression with grouped variables. The estimator \( \hat{\beta}_n \) becomes in this case, adapted fused grouped LASSO median estimator.

The asymptotic properties for \( \hat{\beta}_n \) will be studied under the following assumptions for errors, design and group number \( p \):

(A1) \( (\varepsilon_i)_{1 \leq i \leq n} \) are i.i.d., with the distribution function \( F \) and density function \( f \). The density
function $f$ is continuously, strictly positive in a neighborhood of zero and has a bounded first derivative in the neighborhood of 0. The $\tau$th quantile of $\epsilon_i$ is zero: $\tau = F(0)$.

(A2) There exist constants $0 < m_0 \leq M_0 < \infty$ such that

$$m_0 \leq \lambda_{\min}(n^{-1}\sum_{i=1}^{n}X_iX_i^t) \leq \lambda_{\max}(n^{-1}\sum_{i=1}^{n}X_iX_i^t) \leq M_0.$$  

(A3) $(p/n)^{1/2}\max_{1\leq i \leq n}\|X_i\| \to 0$.

(A4) $p$ is such that $p = O(n^c)$, with $0 \leq c < 1$.

For the smallest nonzero vector norm and on constant $c$ of assumption (A4) we assume:

(A5) Let us denote $h_0 \equiv \min_{1 \leq j \leq p_0}\|\beta_0^j\|$. There exists a constant $M > 0$ such that $M \leq n^{-\alpha}h_0$ and $\alpha > (c-1)/2$.

Concerning the size of the nonzero parameter vectors, we take the following assumption:

(A6) $r^0 = O(p_0)$.

Assumptions (A2), (A3) are standard for LASSO methods and (A1) is classic for quantile regression (see Ciuperca (2016b), Koenker (2005), Zou and Yuan (2008), Wu and Liu (2009)). Assumptions (A3), (A4) are also considered in Ciuperca (2016a), Zou and Zhang (2009) for high-dimensional linear model, while (A5) and (A6) are required for adaptive group LASSO least square estimator in Zhang and Xiang (2015) and in Ciuperca (2016a) for adaptive group LASSO quantile estimator.

For the case $p$ fixed, then $c = 0$, only assumptions (A1) - (A3) will be needed. For the case $p = p_n \to \infty$ as $n \to \infty$, assumptions (A4), (A5) and (A6) are also considered, with $c \in (0, 1)$ in assumption (A3).

In Sections 3 and 4 we will study the adaptive fused group LASSO quantile ($afg\_LASSO\_Q$) estimator $\hat{\beta}_n$ for two cases of the group number: $p$ fixed and $p \to \infty$ as $n \to \infty$, respectively.
3 Case $c = 0$

In this section we will propose and study the asymptotic properties of the $afg\text{-LASSO}_Q$ estimator of the parameter $\beta$ for model (2.1), when the number of groups $p$ is fixed.

Regarding assumptions, as specified above, in order to prove the oracle properties for $\hat{\beta}_n$, only (A1), (A2), (A3) will be needed, with a weaker condition in (A1) on error density $f$. So, the condition that $f$ has a bounded derivative in the neighbourhood of 0 with an weaker condition can be replaced in assumption (A1) by: for every $e \in \text{int}(B)$, $1_r \in \mathbb{R}^r$, we have

$$\lim_{n \to \infty} n^{-1} \sum_{i=1}^{n} \int_0^{1_r} \sqrt{n}|F(e + n^{-1/2}v) - F(e)|dv = \frac{1}{2} f(e) 1_r \Upsilon 1_r.$$ (3.1)

The $r$-vector $1_r$ contains as elements 1. The matrix $\Upsilon$ is defined by (3.2).

Note also that assumption (A3) becomes: $n^{-1} \max_{1 \leq i \leq n} X_i^t X_i \to 0$ and assumption (A2) implies that

$$n^{-1} \sum_{i=1}^{n} X_i X_i^t \to \Upsilon,$$ (3.2)

with $\Upsilon$ a positive definite matrix.

The tuning parameters $\mu_n^{(1)}$, $\mu_n^{(2)}$ and the positive constant $\gamma$ are such that, for $n \to \infty$,

$$\mu_n^{(m)} \to \infty, \quad n^{-1/2} \mu_n^{(m)} \to 0, \quad n^{(\gamma-1)/2} \mu_n^{(m)} \to \infty, \text{ for } m = 1, 2.$$ (3.3)

For $m = 1$, we get the conditions imposed on the tuning parameter by Ciuperca (2016a) for adaptive group LASSO quantile estimator (non fused). Conditions in (3.3) on $\mu_n^{(1)}$ and $\mu_n^{(2)}$ are also found in Viallon et al. (2016), where an adaptive fused LASSO for generalized linear models is considered. For the particular case $\gamma = 1$, for a quantile model without grouped variables ($d = 1$), we obtain the conditions on the tuning parameters imposed by Jiang et al. (2014).
The proofs of all results are given in Section 5 sub-section 5.1.

By the following lemma we show that, when the variables are grouped, the adapted fused group LASSO quantile parameter estimator has the same convergence rate as by classical quantile method, without grouping variables, without adapted fused LASSO penalty. This convergence rate will serve as an essential tool for studying process \( L_n(\beta) \) when \( \beta \) belongs to a neighbourhood of \( \beta^0 \) of order radius \( n^{-1/2} \) and for showing the asymptotic normality of the parameter estimators corresponding to the significant groups.

**Lemma 3.1** Under assumptions (A1), (A2), (A3) and conditions in (3.3) for the tuning parameters, we have, \( n^{1/2} \| \hat{\beta}_n - \beta^0 \| = O_P(1) \).

In order to study the oracle properties of the estimator \( \hat{\beta}_n \), let us consider the index set of the groups selected by the following adaptive fused group LASSO quantile method:

\[
\hat{A}_n \equiv \{ j \in \{1, \cdots, p\}; \| \hat{\beta}_{n,j} \| \neq 0 \}
\]

and \( \hat{A}_c \) its complementary.

The following theorem shows a first oracle property, that the \( afg\_LASSO\_Q \) estimators with indices in the set \( A \) are asymptotically Gaussians.

**Theorem 3.1** Under assumptions (A1), (A2) and (A3) and conditions of (3.3), we have \( \sqrt{n}(\hat{\beta}_n - \beta^0)_{A} \overset{F}{\underset{n \to \infty}{\to}} \mathcal{N}(0, \tau(1 - \tau)f^{-2}(0)\Upsilon_A^{-1}) \), with \( \Upsilon_A \) the submatrix of \( \Upsilon \) with the row and column indices in \( A \).

Compared to the adaptive LASSO quantile method, if an additional penalty fused is considered, we got the same variance matrix for the asymptotic gaussian law (see Ciuperca (2016a)).

In practical applications, the set \( A \) is unknown. In exchange, it can be estimated by \( \hat{A}_n \). Then, for that the estimator \( \hat{\beta}_n \) to be interesting, it is necessary that these two sets coincide with probability
converging to 1, as \( n \) converges to infinity. By the following theorem, we show that the second oracle property, i.e. the sparsity, is satisfied for the \( \text{afgLASSO}_Q \) estimator.

**Theorem 3.2** Under the same assumptions as in Theorem 3.1 we have, \( \lim_{n \to \infty} P[\hat{A}_n = A] = 1 \).

The proof of Theorem 3.2 given in sub-section 5.1 is in two parts. The result \( \lim_{n \to \infty} P[A \subseteq \hat{A}_n] = 1 \) is an immediate consequence of Theorem 3.1. In order to prove \( \lim_{n \to \infty} P[\text{Card}(A^c \cap \hat{A}_n) \geq 1] = 0 \), the proof is quite technical, taking into account already proven properties to \( \hat{\beta}_n \) and imposed conditions for the tuning parameters.

4 **Case \( c > 0 \)**

In this section we consider same model \((2.1)\) with grouped variables, but with the number \( p \) of groups depending on \( n \) and divergent: \( p = p_n \) and \( p_n \to \infty \) as \( n \to \infty \). For readability we keep notation \( p \) instead of \( p_n \). Similarly for \( r = pd \). The main purpose is to show that the \( \text{afgLASSO}_Q \) estimator keeps the oracle properties even though the group number diverges. The proofs of all results are given in Section 5, sub-section 5.2. A major difficulty that appears in the proofs is that the size of vectors and of matrices converges to infinity when \( n \) tends to infinity.

In order to show the main result of this Section, we will first find the convergence rate of adaptive fused group LASSO quantile estimator \( \hat{\beta}_n \) of \( \beta \). Afterwards, we will show that this estimator satisfies the oracle properties. We recall that the two tuning parameters \( \mu_n^{(1)} \) and \( \mu_n^{(2)} \) converge to infinity as \( n \to \infty \).

**Lemma 4.1** Under assumptions (A1)-(A5) and the two tuning parameters \( (\mu_n^{(m)})_{n \in \mathbb{N}} \) satisfying \( \mu_n^{(m)} n^{(c-1)/2-\alpha \gamma} \to 0 \), as \( n \to \infty \), for \( m = 1, 2 \), we have \( \|\hat{\beta}_n - \beta^0\| = O_p((pm^{-1})^{1/2}) \).

We observe that for fixed \( p \), we obtain the result of Lemma 3.1. The convergence rate as \( p \to \infty \) of the \( \text{afgLASSO}_Q \) estimator is the same as that of Ciuperca (2016a) for adaptive group LASSO quantile estimator. Then, the fused penalty doesn’t affect the estimator rate convergence. For the particular case \( c = \alpha = 0 \), the condition imposed on \( \mu_n^{(m)} \), for \( m = 1, 2 \), in Lemma 4.1 is the second
In order to prove the sparsity property, the assumptions used in Lemma 4.1 are sufficient. Since \( p \to \infty \), we need in addition assumption (A6) for showing the asymptotic normality of the \( afg_{Q, LASSO} \) estimators for the significant groups of variables. For the tuning parameters, we consider a generalization for the third condition of (3.3).

**Theorem 4.1** Suppose that assumptions (A1)-(A5) are satisfied and also that the tuning parameters satisfy 
\[
\mu_n^{(m)} n^{-(c-1)}/2 - \alpha \gamma \to 0, \quad \mu_n^{(m)} n^{-c(1+\gamma)+\gamma-1}/2 \to \infty, \quad \text{as } n \to \infty, \quad \text{for } m = 1, 2.
\]

Then:

(i) \( \mathbb{P} [ \hat{A}_n = A ] \to 1 \), as \( n \to \infty \).

(ii) If moreover assumption (A6) holds, for any vector \( u \) of size \( r_0 \) such that \( \| u \| = 1 \), if we denote 
\[
\Upsilon_n, A \equiv n^{-1} \sum_{i=1}^n X_{i,A}X_{i,A}^t, \text{ then, } \sqrt{n}(u^t \Upsilon_n^{-1} u)^{-1/2} u^t (\tilde{\beta}_n - \beta^0)_A \xrightarrow{L} N(0, \tau(1-\tau)f^{-2}(0)).
\]

We observe that, in respect to the case \( p \) fixed, now we first prove the sparsity property. For showing \( \mathbb{P} [ A \subseteq \hat{A}_n ] \to 1 \), we prove that: \( \lim_{n \to \infty} \mathbb{P} [ \min_j \| \hat{\beta}_{n,j} \| > 0 ] = 1 \). For showing \( \lim_{n \to \infty} \mathbb{P} [ \text{Card}(A^c \cap \hat{A}_n) \geq 1 ] = 0 \), we use the asymptotic properties of quantile process and imposed conditions for the tuning parameters. In order to proof the asymptotic normality of \( (\hat{\beta}_n)_A \), we mainly use the sparsity property and we prove that for the penalized process \( L_n(\beta) \), with \( \beta \) in a \( n^{-1/2} \)-neighbourhood of \( \beta^0 \), the penalties are much smaller than the quantile process. Finally, a CLT for the independent random variable sequences is applied.

**Remark 4.1** Results of Lemma 4.1 and of Theorem 4.1 are new even for the particular case of quantile model without grouped variables.

**Remark 4.2** Algorithm and the related numerical part are a very difficult task, firstly since in the process \( G_n(\beta) \) and in the two penalties of (2.3), the variables are grouped. On the other hand, quantile process and penalties are continuous but not differentiable in respect to parameters \( \beta \). The author has not found any numerical work, even for the particular case \( d = 1 \), of ungrouped variables, for a linear quantile model, with adaptive fused LASSO penalty. Consequently, for the method
Another work should be conducted on numerical method, firstly for a quantile model without grouped variables and afterwards for quantile model with grouped variables.

5 Proofs

In this section, the proofs of Lemmas and of Theorems presented in Sections 3 and 4 are presented. In order to study the asymptotic properties of the $\hat{\beta}_n$, we consider the following random variable

$$D_i \equiv (1 - \tau) \mathbb{1}_{\epsilon_i < 0} - \tau \mathbb{1}_{\epsilon_i \geq 0}. \quad (5.1)$$

Obviously, $\mathbb{E}[D_i] = 0$ and $\rho_\tau(\epsilon_i) = -\epsilon_i D_i$.

5.1 Result proofs for $c=0$ case

We start be giving the proofs of results presented in Section 3.

Proof of Lemma 3.1. We show that for all $\epsilon > 0$, there exists a constant $B_\epsilon > 0$ (without loss of generality, we take $B_\epsilon > 0$, otherwise we take $|B_\epsilon|$ sufficiently large such that for $n$ large enough:

$$P \left[ \inf_{\|u\|=1} L_n \left( \beta^0 + B_\epsilon n^{-1/2} u \right) > 0 \right] \geq 1 - \epsilon, \quad (5.2)$$

with $u \in \mathbb{R}^r$, $\|u\| = 1$.

Let $C_1 > 0$ be some constant. We will study the random process: $L_n \left( \beta^0 + C_1 n^{-1/2} u \right) = G_n(\beta^0 + C_1 n^{-1/2} u) - G_n(\beta^0) + \mu_n(1) \sum_{j=1}^p \| \tilde{\beta}_{n,j} \| - \gamma \left[ \| \beta^0 + n^{-1/2} C_1 u \| - \| \beta^0 \| \right] + \mu_n(2) \sum_{j=2}^p \tilde{\omega}_{n,j}(\| \beta^0 - \beta_{j-1}^0 \| - \| \beta_j^0 - \beta_{j-1}^0 \|) + \mu_n(3) \sum_{j=1}^p \tilde{\omega}_{n,j}(\| \beta^0 \| - \| \beta_{j-1}^0 \|) + \mu_n(4) \sum_{j=1}^p \tilde{\omega}_{n,j}(\| \beta^0 \| - \| \beta_{j-1}^0 \|).

For each observation $i$, consider the random variable $R_i \equiv \rho_\tau(\epsilon_i - C_1 n^{-1/2} X_i^t u) - C_1 n^{-1/2} D_i X_i^t u$, with $D_i$ defined by (5.1). Consider also the following random vector $W_n \equiv C_1 n^{-1/2} \sum_{i=1}^n D_i X_i^t$. 

Then the loss term of the random process $L_n (\beta^0 + C_1 n^{-1/2} u)$ can be written:

$$G_n (\beta^0 + C_1 n^{-1/2} u) - G_n (\beta^0) = \mathbb{E} \left[ G_n (\beta^0 + C_1 n^{-1/2} u) - G_n (\beta^0) \right] + W_n u + \sum_{i=1}^{n} (\mathcal{R}_i - \mathbb{E} \mathcal{R}_i). \quad (5.3)$$

For the first term of the right-hand side of (5.3) we have:

$$\mathbb{E} \left[ G_n (\beta^0 + C_1 n^{-1/2} u) - G_n (\beta^0) \right] = \frac{C_1}{2} f(0) \sum_{i=1}^{n} (\mathcal{X}_i^t u)^2 (1 + o(1)). \quad (5.4)$$

For the third term of the right-hand side of (5.3), since the errors $\varepsilon_i$ are i.i.d., we have,

$$\mathbb{E} \left[ \sum_{i=1}^{n} (\mathcal{R}_i - \mathbb{E} \mathcal{R}_i) \right]^2 \leq \sum_{i=1}^{n} \mathbb{E} \mathcal{R}_i^2 \leq \sum_{i=1}^{n} \mathbb{E} \left[ (C_1 n^{-1/2} |X_i^t u|) 1_{|\varepsilon_i| < C_1 n^{-1/2} |X_i^t u|} \right]^2 \leq C_1^2 n^{-1} \sum_{i=1}^{n} |X_i^t u|^2 \mathbb{E} \left[ 1_{|\varepsilon_i| < C_1 n^{-1/2} |X_i^t u|} \right]. \quad (5.5)$$

But, using assumption (A3),

$$\mathbb{E} \left[ 1_{|\varepsilon_i| < C_1 n^{-1/2} |X_i^t u|} \right] \leq C n^{-1/2} \|X_i\| \leq C n^{-1/2} \max_{1 \leq i \leq n} \|X_i\| = o(1). \quad (5.6)$$

Using assumption (A2), relations (5.5) and (5.6) imply: $\mathbb{E} \left[ \sum_{i=1}^{n} (\mathcal{R}_i - \mathbb{E} \mathcal{R}_i) \right]^2 \leq o(1)$. Then, by Bienaymé-Tchebychev inequality, we have

$$\sum_{i=1}^{n} (\mathcal{R}_i - \mathbb{E} \mathcal{R}_i) = o_{P}(1). \quad (5.7)$$

For the second term of the right-hand side of (5.3) we have that random variable $W_n u$ converges in distribution to a centred Gaussian law. Then, taking also into account relations (5.4) and (5.7),

Adaptive Fused LASSO in Grouped Quantile Regression
we obtain that relation (5.3) becomes:

\[
G_n(\beta^0 + C_1 n^{-1/2} u) - G_n(\beta^0) = \left( C_1^2 f(0) \frac{1}{2} n \sum_{i=1}^{n} (X_i^t u)^2 \right) (1 + o_P(1)). \tag{5.8}
\]

Now we study the penalty terms for \( L_n (\beta^0 + C_1 n^{-1/2} u) \).

- For the penalty \( \mu_n^{(1)} \sum_{j=1}^{p} \| \tilde{\beta}_{n,j} \|^{-\gamma} [\|\beta_j^0 + n^{-1/2} C_1 u_j \| - \|\beta_j^0 \|] \), two cases are considered for the index \( j \):
  - if \( j \in A \), then, since the quantile estimator \( \tilde{\beta}_{n,j} \) is consistent, we have with probability converging to 1 as \( n \to \infty \), that \( \mu_n^{(1)} \| \tilde{\beta}_{n,j} \|^{-\gamma} [\|\beta_j^0 + n^{-1/2} C_1 u_j \| - \|\beta_j^0 \|] < C\mu_n^{(1)} n^{-1/2} \| u_j \| \to 0 \), by conditions of (3.3).
  - if \( j \in A^c \), then, taking into account that the convergence rate of \( \tilde{\beta}_{n,j} \) to 0 is \( n^{-1/2} \), this penalty is \( O_p \left( \mu_n^{(1)} \| \tilde{\beta}_{n,j} \|^{-\gamma} n^{-1/2} \| u_j \| \right) = O_p \left( \mu_n^{(1)} n^{(\gamma - 1)/2} \| u_j \| \right) \), which converges to \( \infty \) when \( \| u_j \| \neq 0 \) by (3.3) and it is equal to 0 when \( \| u_j \| = 0 \).

- We will now study the penalty \( \mu_n^{(2)} \sum_{j=2}^{p} \tilde{\omega}_{n,j}^{(2)} (\|\beta_j^0 - \beta_{j-1}^0 + C_1 n^{-1/2} (u_j - u_{j-1}) \| - \|\beta_j^0 - \beta_{j-1}^0 \|) \). We consider the two possible cases for the index \( j \):
  - if \( \beta_j^0 = \beta_{j-1}^0 \), then we have, \( \mu_n^{(2)} \tilde{\omega}_{n,j}^{(2)} (\|\beta_j^0 - \beta_{j-1}^0 + C_1 n^{-1/2} (u_j - u_{j-1}) \| - \|\beta_j^0 - \beta_{j-1}^0 \|) = O_p(\mu_n^{(2)} \tilde{\omega}_{n,j}^{(2)} n^{-1/2} \| u_j - u_{j-1} \|) > 0 \).
  - if \( \beta_j^0 \neq \beta_{j-1}^0 \), then, using conditions (3.3), we obtain, \( \mu_n^{(2)} \tilde{\omega}_{n,j}^{(2)} (\|\beta_j^0 - \beta_{j-1}^0 + C_1 n^{-1/2} (u_j - u_{j-1}) \| - \|\beta_j^0 - \beta_{j-1}^0 \|) = O_p(\mu_n^{(2)} \tilde{\omega}_{n,j}^{(2)} (u_j - u_{j-1})^t n^{-1/2} (\beta_j^0 - \beta_{j-1}^0) \| \beta_j^0 - \beta_{j-1}^0 \|^{-1}) = O_p(n^{-1/2} \mu_n^{(2)} (\beta_j^0 - \beta_{j-1}^0)) = o_P(1) \).

Then, since in the following relation \( O_p(\mu_n^{(m)} n^{(\gamma - 1)/2}) > 0 \), for any \( m = 1, 2 \), and taking into account relation (5.8) together with the study realised on the penalties, we have for \( n \) and \( B \) large...
enough that:

\[
L_n(\beta^0 + B_n n^{-1/2} u) = B_n^2 f(0) \sum_{i=1}^{n} (X^i u)^2 + B_n \left( O_p(\mu_{1n}^1 n^{(\gamma-1)/2}) + O_p(\mu_{1n}^1 n^{-1/2}) \right. \\
+ O_p(\mu_{2n}^2 n^{-1/2}) + O_p(\mu_{2n}^2 n^{(\gamma-1)/2}) \left. \right) .
\]

Taking into account (3.3), we obtain relation (5.2) for \( n \) and \( B_n \) large enough.

**Proof of Theorem 3.1.** For \( u \in \mathbb{R}^r \), let us consider the random process:

\[
L_n(\beta^0 + B_n n^{-1/2} u)
\]

with the process \( L_n \) defined by relation (2.4) and \( u \in \mathbb{R}^r \).

Let’s recall that \( \hat{\beta}_n = \sqrt{n}(\hat{\beta}_n - \beta^0) \) is the minimizer in \( u \) de \( L_n(\beta^0 + n^{-1/2} u) \). In view of the convergence rate of the estimator \( \hat{\beta}_n \) obtained by Lemma 3.1, we will consider \( u \equiv (u_1, \cdots, u_p) \) bounded. On the other hand, the process \( L_n(\beta^0 + n^{-1/2} u) \) can be written:

\[
L_n(\beta^0 + n^{-1/2} u) = [z_n^t u + B_n(u)] + \mu_{1n}^{(1)} \sum_{j=1}^p \hat{\omega}_{n,j}^{(1)} \left( \|\beta^0_j + n^{-1/2} u_j\| - \|\beta^0_j\| \right) \frac{\sqrt{n}}{\sqrt{n}} + \mu_{2n}^{(2)} \sum_{j=2}^p \hat{\omega}_{n,j}^{(2)} \left( \|\beta^0_j + \frac{u_j}{\sqrt{n}} - \left( \beta^0_{j-1} + \frac{u_{j-1}}{\sqrt{n}} \right) \| - \|\beta^0_j - \beta^0_{j-1}\| \right) \frac{\sqrt{n}}{\sqrt{n}} .
\]

(5.9)

with

\[
z_n \equiv \frac{1}{\sqrt{n}} \sum_{i=1}^{n} X_i D_i, \quad B_n(u) \equiv \sum_{i=1}^{n} \int_0^{X_i u/\sqrt{n}} [\mathbb{1}_{\varepsilon_i < t} - \mathbb{1}_{\varepsilon_i < 0}] dt,
\]

and the random variable \( D_i \) defined by (5.1). Since \( E[D_i] = 0 \), we have that \( E[z_n] = 0 \). For the loss term (the first bracket of the right-hand side) of (5.9), by the CLT, using (A1), (A2) and (A3), we have

\[
z_n^t u \xrightarrow{\mathcal{L}} z^t u, \quad B_n(u) \xrightarrow{p} 1 \text{ for } f(0)u^t \mathbf{Y}u,
\]

(5.10)

with the random \( r \)-vector \( z \sim \mathcal{N}(0_r, \tau(1 - \tau) \mathbf{Y}) \).

We now study the two penalties of the right-hand side of (5.9).
For the first penalty term of \( L_n(\beta^0 + n^{-1/2}u) \) of (5.9), we have, using the conditions of relation (5.3), that,

\[
\mu_n \sum_{j=1}^{p} \tilde{\omega}_{n,j} \left( \left\| \beta_j^0 \right\| + \frac{u_j}{\sqrt{n}} \right) - \left\| \beta_j^0 \right\| \right) \frac{\sqrt{n}}{\sqrt{n}} \frac{p}{n} \rightarrow \infty \sum_{j=1}^{p} W^{(1)}(\beta_j^0, u),
\]

(5.11)

with

\[
W^{(1)}(\beta_j^0; u_j) \equiv \begin{cases} 
0, & \text{if } \beta_j^0 \neq 0_d \\
0, & \text{if } \beta_j^0 = 0_d \text{ and } u_j = 0_d \\
\infty, & \text{if } \beta_j^0 = 0_d \text{ and } u_j \neq 0_d.
\end{cases}
\]

For the second penalty term of \( L_n(\beta^0 + n^{-1/2}u) \) of (5.9), consider the following notations:

\( \mathcal{P}_{2,j} = \sqrt{n} \left( \left\| \beta_j^0 - \beta_{j-1}^0 + n^{-1/2}(u_j - u_{j-1}) \right\| - \left\| \beta_j^0 - \beta_{j-1}^0 \right\| \right) \) and \( \mathcal{S}_{2,j} = \mu_n (\tilde{\omega}_{n,j} n^{-1/2}) \mathcal{P}_{2,j} \).

For \( \beta_j^0 = \beta_{j-1}^0 \), two cases are possible.

If \( \beta_j^0 = \beta_{j-1}^0 \), then \( \mathcal{P}_{2,j} = \left\| u_j - u_{j-1} \right\| \leq C \). On the other hand, since \( \left\| \tilde{\beta}_{n,j} - \beta_{n,j-1} \right\| = O(n^{-1/2}) \), using conditions (5.3), we have \( \mu_n (\tilde{\omega}_{n,j} n^{-1/2}) = C \mu_n (\tilde{\beta}_{n,j} - \beta_{n,j-1} \right\| n^{-1/2} \frac{p}{n} \rightarrow \infty \). Then

\[
\mathcal{S}_{2,j} \xrightarrow{n \to \infty} \begin{cases} 
0, & \text{if } u_j = u_{j-1} \\
\infty, & \text{if } u_j \neq u_{j-1}.
\end{cases}
\]

If \( \beta_j^0 \neq \beta_{j-1}^0 \), since \( \lim_{n \to \infty} \mathcal{P}_{2,j} = (u_j - u_{j-1}) i(\beta_j^0 - \beta_{j-1}^0) \|\beta_j^0 - \beta_{j-1}^0 \|^{-1} \), we have that, \( \mathcal{S}_{2,j} \xrightarrow{n \to \infty} 0 \).

So, considering both cases, we can write

\[
\sum_{j=1}^{p} \mathcal{S}_{2,j} \xrightarrow{n \to \infty} W^{(2)}(\beta_j^0, \beta_{j-1}^0; u_j, u_{j-1}),
\]

(5.12)

with

\[
W^{(2)}(\beta_j^0, \beta_{j-1}^0; u_j, u_{j-1}) \equiv \begin{cases} 
0, & \text{if } \beta_j^0 \neq \beta_{j-1}^0 \\
0, & \text{if } \beta_j^0 = \beta_{j-1}^0 \text{ and } u_j = u_{j-1} \\
\infty, & \text{if } \beta_j^0 = \beta_{j-1}^0 \text{ and } u_j \neq u_{j-1}.
\end{cases}
\]
Thus, for process (5.9), taking into account of relations (5.10), (5.11) and (5.12), we obtain,

$$L_n(\beta^0 + n^{-1/2}u) \xrightarrow{\mathcal{L}} L(u),$$

with, the limit random variable,

$$L(u) \equiv z'u + \frac{1}{2}f(0)u'Yu + \sum_{j=1}^{p} W^{(1)}(\beta^0_j; u_j) + \sum_{j=2}^{p} W^{(2)}(\beta^0_j, \beta^0_{j-1}; u_j, u_{j-1}).$$

But \(\hat{u}_n = \arg\min_u L_n(u).\) On the other hand, \(L(u)\) is bounded for any \(j\) such that \(\beta^0_j \neq 0_d\), when \(\beta^0_j \neq \beta^0_{j-1}\) or when \((\beta^0_j = \beta^0_{j-1}, u_j = u_{j-1})\). In these cases, the expression of \(L(u)\) is:

$$L(u) \equiv z'u + 2^{-1}f(0)u'Yu. \quad \text{Since the minimizer of } L(u) \text{ is the gaussian vector } f^{-1}(0)z, \text{ we deduce that } \hat{u}_n \text{ is asymptotically Normal and the theorem follows.}$$

\[\blacksquare\]

**Proof of Theorem 3.2** By Theorem 3.1, for any \(j \in A\) we have that \(\sqrt{n}(\hat{\beta}_{n,j} - \beta^0_j) \xrightarrow{\mathcal{L}} \mathcal{N}(0_d, \tau(1-\tau)f^{-2}(0)\Upsilon_{A_j})\), with \(\Upsilon_{A_j}\) a square matrix of size \(d \times d\), the submatrix of \(\Upsilon\). Since \(\beta^0_j \neq 0_d\), then \(j \in \hat{A}_n\). Thus

$$\lim_{n \to \infty} P[A \subseteq \hat{A}_n] = 1. \quad (5.13)$$

To finish the proof, we show that, \(\lim_{n \to \infty} P[\text{Card}(A \cap \hat{A}_n) \geq 1] = 0\). We assume without loss of generality that \(A \cap \hat{A}_n = \{j_1\}\). If this intersection contains more than one element, the calculations are the same, except they are painful.

In addition to the estimator \(\hat{\beta}_n\) which has the \(j_1\)th group such that \(A \cap \hat{A}_n = \{j_1\}\), let us consider a second estimator \(\beta^*\) for \(\beta\). Taking \(\beta^* \equiv (\hat{\beta}_{n,A}, 0_{A^c})\), we will show that \(Q_n(\hat{\beta}_n) > Q_n(\beta^*)\) with a probability converging to 1.
For this, we will study the following difference:  

$$Q_n(\hat{\beta}_n) - Q_n(\beta^*) = \sum_{i=1}^{n} \left[ \rho_r(Y_i - \mathbb{X}_i', \hat{\beta}_n) - \rho_r(\varepsilon_i) \right] - \sum_{i=1}^{n} \left[ \rho_r(Y_i - \mathbb{X}_i', \beta^*) - \rho_r(\varepsilon_i) \right] + \mu_n^{(1)} \omega_n^{(1)} \| \hat{\beta}_{n:j_1} \|

+ \mu_n^{(2)} \left[ \omega_n^{(2)} \| \hat{\beta}_{n:j_1} - \hat{\beta}_{n:j_1-1} \| + \omega_n^{(2)} \| \hat{\beta}_{n:j_1+1} - \hat{\beta}_{n:j_1} \| - \omega_n^{(2)} \| \hat{\beta}_{n:j_1+1} \| \right].$$

Similarly as in the proof of Theorem 3.1, we have that, $\sum_{i=1}^{n} \left[ \rho_r(Y_i - \mathbb{X}_i', \hat{\beta}_n) - \rho_r(\varepsilon_i) \right]$ and $\sum_{i=1}^{n} \left[ \rho_r(Y_i - \mathbb{X}_i', \beta^*) - \rho_r(\varepsilon_i) \right]$ are bounded, with a probability converging to 1. Then, with a probability converging to 1, we have that,

$$Q_n(\hat{\beta}_n) - Q_n(\beta^*) = C + \mu_n^{(1)} \omega_n^{(1)} \| \hat{\beta}_{n:j_1} \| + \mu_n^{(2)} \left[ \omega_n^{(2)} \| \hat{\beta}_{n:j_1} - \hat{\beta}_{n:j_1-1} \| - \| \hat{\beta}_{n:j_1-1} \| \right] + \omega_n^{(2)} \| \hat{\beta}_{n:j_1+1} - \hat{\beta}_{n:j_1} \| - \| \hat{\beta}_{n:j_1+1} \| \right).$$

\[ (5.14) \]

Since $j_1 \in \mathcal{A}$, we have that $\hat{\beta}_{n:j_1} \xrightarrow{p} 0$ and then $\omega_n^{(1)} \| \hat{\beta}_{n:j_1} \| = \mu_n^{(1)} n^{-1/2} \| n^{1/2} \hat{\beta}_{n:j_1} \| n^{\gamma/2} \| n^{1/2} \hat{\beta}_{n:j_1} \|^{-\gamma} = O_p(\mu_n^{(1)} n^{(\gamma-1)/2}) \xrightarrow{p} \infty.$

We will study now the two penalties, in $\mu_n^{(1)}$ and in $\mu_n^{(2)}$ of (5.14). For $\hat{\beta}_{j_1-1}, \hat{\beta}_{j_1}^{(0)}, \hat{\beta}_{j_1+1}^{(0)}$ three cases are possible.

\textbf{Case 1.} $\hat{\beta}_{j_1} \neq \hat{\beta}_{j_1-1}$ and $\hat{\beta}_{j_1+1} \neq \hat{\beta}_{j_1}^{(0)}$.

In this case, we have that, the weights $\omega_n^{(2)}$ and $\omega_n^{(2)}$ converge in probability for $n \rightarrow \infty$ to a strictly positive bounded constant. On the other hand, we have the following obvious inequalities, with probability 1: $\| \hat{\beta}_{n:j_1} - \hat{\beta}_{n:j_1-1} \| - \| \hat{\beta}_{n:j_1-1} \| \geq -\| \hat{\beta}_{n:j_1} \|$ and $\| \hat{\beta}_{n:j_1+1} - \hat{\beta}_{n:j_1} \| - \| \hat{\beta}_{n:j_1+1} \| \geq -\| \hat{\beta}_{n:j_1} \|$. Then, with probability 1, we have,

$$\mu_n^{(1)} \omega_n^{(1)} \| \hat{\beta}_{n:j_1} \| + \mu_n^{(2)} \omega_n^{(2)} \| \hat{\beta}_{n:j_1} - \hat{\beta}_{n:j_1-1} \| - \| \hat{\beta}_{n:j_1-1} \| \| \hat{\beta}_{n:j_1} \| \geq \mu_n^{(1)} \omega_n^{(1)} - \mu_n^{(2)} \omega_n^{(2)} \| \hat{\beta}_{n:j_1} \|$$

and since $n^{1/2} \| \hat{\beta}_{n:j_1} \|, n^{1/2} \| \hat{\beta}_{n:j_1} \|^{-\gamma}$ are bounded with probability converging to 1, since $n^{(\gamma-1)/2} \mu_n^{(1)}$
\[ \rightarrow \infty, \text{ we have that the above relation is} \]

\[ = n^{-1/2} \left[ \mu_n^{(1)} \tilde{\omega}_{n:j_1}^{(1)} - \mu_n^{(2)} \tilde{\omega}_{n:j_1}^{(2)} \right] \| n^{1/2} \beta_{n:j_1} \| = O_p\left(n^{-1/2} \mu_n^{(1)} \tilde{\omega}_{n:j_1}^{(1)} \right) \]

\[ = O_p\left(n^{-1/2} \mu_n^{(1)} n^{\gamma/2} \| n^{1/2} \beta_{n:j_1} \|^{-\gamma} \right) \xrightarrow{\frac{p}{n\to\infty}} \infty. \]

For the following term of the penalty, we have:

\[ \mu_n^{(2)} \tilde{\omega}_{n:j_1+1}^{(2)} \left( \| \beta_{n:j_1+1} \| - \| \beta_{n:j_1} \| + \| \beta_{n:j_1+1} \| \right) \geq -\mu_n^{(2)} \tilde{\omega}_{n:j_1+1}^{(2)} \| \beta_{n:j_1} \| \]

\[ = O_p\left( - C n^{-1/2} \mu_n^{(2)} \| n^{1/2} \beta_{n:j_1} \| \right) = o_p(1). \]

We have used the fact that \( \tilde{\omega}_{n:j_1+1}^{(2)} \) converges in probability, for \( n \to \infty \), to a strictly positive bounded constant, \( n^{-1/2} \mu_n^{(2)} \to 0 \) and \( \| n^{1/2} \beta_{n:j_1} \| \) is bounded, with probability converging to 1.

Thus, for relation (5.14), since \( \mu_n^{(1)} n^{(\gamma-1)/2} \| n^{1/2} \beta_{n:j_1} \|^{-\gamma} \xrightarrow{\frac{p}{n\to\infty}} \infty \), we have with a probability converging to 1, that

\[ Q_n(\beta_n) - Q_n(\beta^*) > C + \mu_n^{(1)} n^{(\gamma-1)/2} \| n^{1/2} \beta_{n:j_1} \|^{-\gamma} + o_p(1) > 0. \] (5.15)

**Case 2.** \( \beta^0_{j_1} \neq \beta^0_{j_1-1} \) and \( \beta^0_{j_1+1} = \beta^0_{j_1} \) (or vice versa, the calculations are the same).

Since \( \beta^0_{j_1} = 0 \), then \( \beta^0_{j_1+1} = 0 \) and \( \beta^0_{j_1-1} \neq 0 \).

Since \( \mathcal{A}^c \cap \mathcal{A}_n = \{ j_1 \} \), then \( j_1 + 1 \notin \mathcal{A}_n \) and thus \( \beta_{n:j_1+1} = 0 \). Therefore, the weight \( \tilde{\omega}_{n:j_1}^{(2)} \) converges for \( n \to \infty \) to a strictly positive bounded constant and \( \tilde{\omega}_{n:j_1+1}^{(2)} \xrightarrow{\frac{p}{n\to\infty}} \infty \). Then

\[ \mu_n^{(1)} \tilde{\omega}_{n:j_1}^{(1)} \| \beta_{n:j_1} \| + \mu_n^{(2)} \left( \| \beta_{n:j_1} - \beta_{n:j_1-1} \| - \| \beta_{n:j_1-1} \| \right) + \tilde{\omega}_{n:j_1+1}^{(2)} \| \beta_{n:j_1} \| \]

\[ \geq \mu_n^{(1)} \tilde{\omega}_{n:j_1}^{(1)} \| \beta_{n:j_1} \| + \mu_n^{(2)} \left( - \tilde{\omega}_{n:j_1}^{(2)} \| \beta_{n:j_1} \| + \tilde{\omega}_{n:j_1+1}^{(2)} \| \beta_{n:j_1} \| \right) \]

\[ \geq \mu_n^{(1)} \tilde{\omega}_{n:j_1}^{(1)} \| \beta_{n:j_1} \| + \mu_n^{(2)} \tilde{\omega}_{n:j_1+1}^{(2)} \| \beta_{n:j_1} \| (1 + o_p(1)) \xrightarrow{\frac{p}{n\to\infty}} \infty, \]

19
and thus, for all $\epsilon > 0$,

$$
\lim_{n \to \infty} P \left[ Q_n(\hat{\beta}_n) - Q_n(\beta^*) > \epsilon \right] = 1.
$$

(5.16)

**Case 3.** $\beta^0_{j_1} = \beta^0_{j_1-1} = \beta^0_{j_1+1}$.

In this case, we have $\hat{\beta}_{n;j_1} \neq 0$, $\hat{\beta}_{n;j_1-1} = \hat{\beta}_{n;j_1+1} = 0$. The penalty in this case is:

$$
\mu_n (1) \omega_{n;j_1}^{(1)} \| \hat{\beta}_{n;j_1} \| + \mu_n (2) \omega_{n;j_1}^{(2)} \left[ \omega_{n;j_1}^{(2)} + \omega_{n;j_1+1}^{(2)} \right] \| \hat{\beta}_{n;j_1} \| \overset{P}{\to} \infty,
$$

which means for relation (5.14), that for all $\epsilon > 0$,

$$
\lim_{n \to \infty} P \left[ Q_n(\hat{\beta}_n) - Q_n(\beta^*) > \epsilon \right] = 1.
$$

(5.17)

Thus, in all three cases, taking into account (5.14), (5.15), (5.16), (5.17), we get:

$$
\lim_{n \to \infty} P \left[ Q_n(\hat{\beta}_n) > Q_n(\beta^*) \right] = 1,
$$

which implies that, $\hat{\beta}_n$ is not the minimizer of $Q_n$. Therefore, $\lim_{n \to \infty} P[j_1 \in A^c \cap \hat{A}_n] = 0$ and the proof is finished.

\[■\]

### 5.2 Result proofs for $c > 0$ case

We present now the proofs of the results stated in Section 4. For some results, we will consider obtained results in Ciuperca (2016a) for asymptotic behaviour of the non fused adaptive group LASSO quantile estimator.

**Proof of Lemma 4.1** Let be a positive constant $C_1$ and a $r$-vector $u$ such that $\|u\| = 1$. For the
process $L_n$ defined by (2.4), let us consider

$$L_n \left( \beta^0 + C_1 \sqrt{\frac{p}{n}} \mathbf{u} \right) = G_n \left( \beta^0 + C_1 \sqrt{\frac{p}{n}} \mathbf{u} \right) - G_n(\beta^0) + \sum_{j=1}^{p} \mu_n^{(1)} \hat{\omega}_{n,j}^{(1)} \left[ \| \beta^0_j + \sqrt{\frac{p}{n} C_1} \mathbf{u}_j \| - \| \beta^0_j \| \right]$$

$$+ \mu_n^{(2)} \sum_{j=2}^{p} \hat{\omega}_{n,j}^{(2)} \left[ \| \beta^0_j + \sqrt{\frac{p}{n} C_1} \mathbf{u}_j - \left( \beta^0_{j-1} + \sqrt{\frac{p}{n} C_1} \mathbf{u}_{j-1} \right) \| - \| \beta^0_j - \beta^0_{j-1} \| \right] \equiv T_1 + T_2 + T_3. \quad (5.18)$$

For $T_1, T_2$, using $\mu_n^{(1)} n^{c-1/2-\alpha \gamma} \to 0$, proceeding as in the proof of Theorem 3 of Ciuperca (2016a), we get:

$$T_1 + T_2 > C_2^2 f(0) p \left( \frac{1}{n} \sum_{i=1}^{n} \mathbf{u}_i \mathbf{X}_i \mathbf{X}_i^T \right) \left( 1 + o_p(1) \right) - C_1 O_p(p). \quad (5.19)$$

For $T_3$, we have:

$$T_3 \geq \mu_n^{(2)} \sum_{\{j: \beta^0_j \neq \beta^0_{j-1} \}} \hat{\omega}_{n,j}^{(2)} \left[ \| \beta^0_j + \sqrt{\frac{p}{n} C_1} \mathbf{u}_j - \left( \beta^0_{j-1} + \sqrt{\frac{p}{n} C_1} \mathbf{u}_{j-1} \right) \| - \| \beta^0_j - \beta^0_{j-1} \| \right]$$

$$\geq -C_1 \sqrt{\frac{p}{n} \mu_n^{(2)}} \sum_{\{j: \beta^0_j \neq \beta^0_{j-1} \}} \hat{\omega}_{n,j}^{(2)} \| \mathbf{u}_j - \mathbf{u}_{j-1} \| \geq -C_1 O_p(p) \quad (5.20)$$

by similar reasoning to that $T_1$, using also condition $\mu_n^{(2)} n^{c-1/2-\alpha \gamma} \to 0$ and assumptions (A4), (A5).

Taking into account (5.18), (5.19) and (5.20), we have for $n$ and $C_1$ large enough, that for all $\epsilon > 0$:

$$\mathbb{P} \left[ \inf_{\| \mathbf{u} \|=1} L_n \left( \beta^0 + C_1 \sqrt{\frac{p}{n}} \mathbf{u} \right) > 0 \right] \geq 1 - \epsilon,$$

and the theorem follows. \[\blacksquare\]

**Proof of Theorem 4.1** (i) We show, as for the case $p$ fixed, that $\lim_{n \to \infty} \mathbb{P}[\text{Card}(A^c \cap \hat{A}_n) \geq 1] = 0$. Therefore we not give some calculation details. We assume without loss of generality that
\( \mathcal{A}^c \cap \hat{\mathcal{A}}_n = \{ j_1 \} \). We consider the second estimator \( \beta^* = (\hat{\beta}_{n, \mathcal{A}^c}, 0) \) of \( \beta \) and we will show that \( Q_n(\hat{\beta}_n) > Q_n(\beta^*) \) with a probability converging to 1. We then study the following difference:

\[
Q_n(\hat{\beta}_n) - Q_n(\beta^*) = \sum_{i=1}^n \left[ \rho_r(Y_i - X_i'\hat{\beta}_n) - \rho_r(\varepsilon_i) \right] - \sum_{i=1}^n \left[ \rho_r(Y_i - X_i'\beta^*) - \rho_r(\varepsilon_i) \right]
\]

\[+ \mu_n^{(1)} \hat{\omega}_{n;j_1}^{(1)} \| \hat{\beta}_{n;j_1} \| + \mu_n^{(2)} \left[ \hat{\omega}_{n;j_1}^{(2)} \| \hat{\beta}_{n;j_1} - \hat{\beta}_{n;j_1-1} \| + \hat{\omega}_{n;j_1+1}^{(2)} \| \hat{\beta}_{n;j_1+1} - \hat{\beta}_{n;j_1} \| \right]. \quad (5.21)\]

Under assumptions (A1)-(A4), we have, as in the proof of Theorem 4 of Ciuperca (2016a), that:

\[
\sum_{i=1}^n \left[ \rho_r(Y_i - X_i'\hat{\beta}_n) - \rho_r(\varepsilon_i) \right] - \sum_{i=1}^n \left[ \rho_r(Y_i - X_i'\beta^*) - \rho_r(\varepsilon_i) \right] = O_p(n\|\hat{\beta}_n - \beta^*\|^2) = O_p(p) = O_p(n^\gamma). \quad (5.22)
\]

For the first term of the penalty of (5.21), we have:

\[
0 < \mu_n^{(1)} \hat{\omega}_{n;j_1}^{(1)} \| \hat{\beta}_{n;j_1} \| = \mu_n^{(1)} O_p \left( \frac{p}{n} \right)^{(1-\gamma)/2} = \mu_n^{(1)} O_p(n^{(c-1)(1-\gamma)/2}). \quad (5.23)
\]

Since \( j_1 \in \mathcal{A}^c \) and also \( \mu_n^{(1)} n^{(c-1)(1+\gamma-1)/2} \to \infty \), as \( n \to \infty \), we have that term (5.23) dominates (5.22).

Now we study the penalty corresponding to \( \mu_n^{(2)} \), by considering the three possible cases for \( \beta_{j_1-1}', \beta_{j_1}', \beta_{j_1+1}' \).

**Case 1.** \( \beta_{j_1-1}' \neq \beta_{j_1-1} \) and \( \beta_{j_1+1}' \neq \beta_{j_1} \).

Then \( \hat{\omega}_{n;j_1}^{(2)} = \| \hat{\beta}_{j_1} - \beta_{j_1}' \| - \gamma = \| \hat{\beta}_{j_1 - \beta_{j_1-1}} - \beta_{j_1-1}' \| - \gamma = O_p((pn^{-1/2})-\gamma) = O_p(p^{-1/2}) \) and \( \hat{\omega}_{n;j_1}^{(1)} = O_p((pm^{-1/2})-\gamma) = O_p(n^{-\gamma}) \). On the other hand, \( \hat{\omega}_{n;j_1}^{(1)} = O_p(p^{-1/2}) \).

Since \( \alpha > (c-1)/2 \), then \( \hat{\omega}_{n;j_1}^{(1)} \gg \hat{\omega}_{n;j_1}^{(2)} \), with a probability converging to 1. Therefore, \( \mu_n^{(1)} \hat{\omega}_{n;j_1}^{(1)} \| \hat{\beta}_{n;j_1} \| + \mu_n^{(2)} \hat{\omega}_{n;j_1}^{(2)} \| \hat{\beta}_{n;j_1} - \hat{\beta}_{n;j_1-1} \| \geq \mu_n^{(1)} \hat{\omega}_{n;j_1}^{(1)} \| \hat{\beta}_{n;j_1} \| + O_p(p^{-1/2}) \frac{p}{n} \to \infty \).

On the other hand, \( \mu_n^{(2)} \hat{\omega}_{n;j_1+1}^{(2)} \| \hat{\beta}_{n;j_1+1} - \hat{\beta}_{j_1+1} \| = O_p((pm^{-1/2}) + \| \hat{\beta}_{j_1+1} - \beta_{j_1+1}' \| - \gamma, with \| \hat{\beta}_{j_1+1} - \beta_{j_1+1}' \| = O_p(n^{(c-1)/2} + n^{\gamma}). Thus, \( \hat{\omega}_{n;j_1}^{(1)} \gg \)
\( \hat{\omega}_{n;j_1+1}^{(2)} \), with a probability converging to 1.

In conclusion, the right-hand side of \( Q_{n}(\hat{\beta}_n) - Q_{n}(\beta^*) \) of relation (5.21) is dominated by \( \mu_{n}^{(1)} \hat{\omega}_{n;j_1}^{(1)} \| \hat{\beta}_{n;j_1} \| \), which converges in probability to \( \infty \).

**Case 2.** \( \beta_0^{j_1} \neq \beta_0^{j_1-1} \) and \( \beta_0^{j_1+1} = \beta_0^{j_1} = 0 \) (or vice versa).

In this case, we have, \( \hat{\omega}_{n;j_1}^{(2)} = \| \hat{\beta}_{j_1} - \hat{\beta}_{j_1-1} \|^{-\gamma} = O_{p} \left( (pn^{-1})^{1/2} - \beta_0^{j_1-1} \|^{-\gamma} \right) = O_{p} \left( n^{-\alpha \gamma} \right) \). Then, \( \hat{\omega}_{n;j_1}^{(1)} \gg \hat{\omega}_{n;j_1}^{(2)} \), with a probability converging to 1.

We also have that \( \hat{\omega}_{n;j_1+1}^{(2)} = \| \hat{\beta}_{j_1+1} - \hat{\beta}_{j_1} \|^{-\gamma} = O_{p} \left( (pn^{-1})^{-\gamma/2} \right) = O_{p} \left( n^{(1-c)\gamma/2} \right) \gg \hat{\omega}_{n;j_1}^{(2)} \), with probability converging to 1.

Afterwards, relations are similar to those of the fixed \( p \) case and we deduce (5.16).

**Case 3.** \( \beta_0^{j_1} = \beta_0^{j_1-1} = \beta_0^{j_1+1} \), is similar to the fixed \( p \) case to derive relation (5.17).

Thus, in all three cases, we have: \( Q_{n}(\hat{\beta}_n) > Q_{n}(\beta^*) \) with a probability converging to one, which implies \( \hat{\beta}_n \) is not the minimizer of \( Q_{n} \). Thus, \( \lim_{n \to \infty} P[j_1 \in \hat{A} \cap \hat{A}_n] = 0 \).

To complete the demonstration of claim (i) we need to show that \( P[A \subseteq \hat{A}_n] \to 1 \). For this, we prove that:

\[
\lim_{n \to \infty} P \left[ \min_{j \in A} \| \hat{\beta}_{n;j} \| > 0 \right] = 1.
\]

The proof is similar to that of Theorem 4 of Ciuperca (2016a).

(ii) Taking into account claim (i) and assumption (A6), the estimator \( \hat{\beta}_n \) can be written, with a probability converging to 1, as \( \hat{\beta}_n = \beta^0 + (pn^{-1})^{1/2} \delta \), with \( \delta = (\delta_A, \delta_{A^c}), \delta_A = 0_{r \to \phi}, \| \delta_A \| \leq C \).

Then, we will consider the parameters of the form \( \beta = \beta^0 + (pn^{-1})^{1/2} \delta \).

In order to prove claim (ii), let us consider the following penalized random process:

\[
L_n \left( \beta^0 + \sqrt{\frac{P}{n}} \delta \right) = \sum_{i=1}^{n} \left[ \rho_r \left( Y_i - X_i^t (\beta^0 + \sqrt{\frac{P}{n}} \delta) \right) - \rho_r (\varepsilon_i) \right] + P_1 + P_2, \quad (5.24)
\]
Adaptive Fused LASSO in Grouped Quantile Regression

with the penalties, \( \mathcal{P}_1 \equiv \mu_n^{(1)} \sum_{j=1}^{p} \tilde{\omega}_{n;j}^{(1)} \| \beta_j - \beta_0^j \| \) and \( \mathcal{P}_2 \equiv \mu_n^{(2)} \sum_{j=2}^{p} \tilde{\omega}_{n;j}^{(2)} \| \beta_j - \beta_{j-1} - \beta_0^j \| \).

For the first term of the right-hand side of (5.24), we have

\[
\sum_{i=1}^{n} \left[ \rho_{\tau} \left( Y_i - X_i \beta^0 + \sqrt{\frac{p}{n}} \delta \right) - \rho_{\tau}(\varepsilon_i) \right] = n \left( \frac{1}{n} \sum_{i=1}^{n} X_i \delta [\mathbb{I}_{\varepsilon_i < -\tau}] + \frac{1}{n} \sum_{i=1}^{n} \int_{0}^{\infty} \mathbb{I}_{\varepsilon_i \leq t} dt \right) \equiv n(J_1 + J_2).
\]

As in the proof of Theorem 4 of Ciuperca (2016a), we obtain that

\[
\mathbb{E}[J_2] = C f(0)n^{-1},
\]

also that

the difference of the quantile processes is:

\[
\sum_{i=1}^{n} \left[ \rho_{\tau} \left( Y_i - X_i \beta^0 + \sqrt{\frac{p}{n}} \delta \right) - \rho_{\tau}(\varepsilon_i) \right] = \sqrt{\frac{p}{n}} \sum_{i=1}^{n} X_i \delta [\mathbb{I}_{\varepsilon_i < 0} - \mathbb{I}_{\varepsilon_i \leq 0}] + \frac{f(0)}{2} p \delta \mathbb{I}_{\varepsilon_i \leq t} [\mathbb{I}_{\varepsilon_i < 0} - \mathbb{I}_{\varepsilon_i \leq 0}] dt \equiv n(J_1 + J_2).
\]

and for the first penalty of (5.24), that,

\[
|\mathcal{P}_1| \leq O_p \left( \mu_n^{(1)} n^{(c-1)/2-\alpha} \right). \tag{5.26}
\]

This last relation implies that

\[
|\mathcal{P}_1| (n \mathbb{E}[J_2])^{-1} = O_p \left( \mu_n^{(1)} n^{(c-1)/2-\alpha} \right) = o_p(1),
\]

by condition imposed on \( \mu_n^{(1)} \).

Let us now consider penalty \( \mathcal{P}_2 \) of (5.24). Using assumptions (A4), (A5), we have,

\[
|\mathcal{P}_2| \leq C p \mu_n^{(2)} \max_{j \in A \setminus \{1\}} \left( \tilde{\omega}_{n;j}^{(2)} \right) \left( \frac{p}{n} \right)^{1/2} \leq O_p \left( n^{\epsilon p n^{(c-1)/2-\alpha}} \mu_n^{(2)} \max_{j \in A \setminus \{1\}} \left( \tilde{\omega}_{n;j}^{(2)} \right) \right) = O_p \left( n^{(3c-1)/2} \mu_n^{(2)} n^{-\alpha} \right).
\]

Thus, by condition imposed to \( \mu_n^{(2)} \), we have,

\[
\frac{|\mathcal{P}_2|}{n \mathbb{E}[J_2]} = O_p \left( \mu_n^{(2)} n^{(c-1)/2-\alpha} \right) = o_p(1). \tag{5.27}
\]
In conclusion, taking into account relations (5.24)-(5.27), we have that:

\[ L_n \left( \beta^0 + \sqrt{\frac{p}{n}} \delta \right) = \sqrt{\frac{p}{n}} \sum_{i=1}^{n} X_i^t \delta_A \mathbb{1}_{\varepsilon_i < 0 - \tau} + \frac{f(0)}{2} p \delta_A \mathbf{Y}_n \delta_A (1 + o_p(1)). \]

The minimizer of the right-hand side of the last equation is:

\[ \sqrt{\frac{p}{n}} \delta_A = \frac{1}{n} \frac{1}{f(0)} \mathbf{Y}_n^{-1} \left( \sum_{i=1}^{n} X_i \mathbb{1}_{\varepsilon_i \leq 0 - \tau} \right). \]

Claim (ii) follows by taking into account the fact that \( \hat{\beta}_A - \beta^0_A = (pm^{-1})^{1/2} \delta_A \) and by applying the CLT for the following independent random variable sequence: \( \left( (f(0))^{-1} \mathbf{u}^t \mathbf{Y}_n^{-1} X_i \mathbb{1}_{\varepsilon_i \leq 0 - \tau} \right)_{1 \leq i \leq n} \),

with \( \mathbf{u} \) a \( p \)-vector such that \( \| \mathbf{u} \| = 1. \)
