1. Introduction

Lung cancer is the leading cause of cancer-related mortality worldwide, and non-small cell lung cancer (NSCLC) accounts for –85% of all lung cancers [1]. Despite improvements in the chemotherapeutic drugs used over time, the 5-year survival rate of NSCLC patients is only 18% [1]. Although the response rates in subsets of NSCLC with tyrosine kinase receptors (mutant EGFR, ALK, and ROS1) were high, drug resistance has been a major challenge [2]. One reason accounting for drug resistance is that the ability to repress E-cadherin directly or indirectly [12], as well as the increase in mesenchymal cell markers (for example, vimentin and N-cadherin) [8]. Loss of E-cadherin expression is considered as a key event during EMT [9–11]. EMT-inducing transcription factors possess the ability to repress E-cadherin directly or indirectly [12], as well as to promote the expression of matrix metalloproteases to activate the remodeling of the basement membrane and invasion into surrounding tissues [13].

Twist-related protein 1 (TWIST1) plays an essential role in the carcinogenesis and metastasis of NSCLC. Our aims were to identify the molecule at the downstream of TWIST1 and to evaluate its potential as a diagnostic and a prognostic marker in NSCLC.

Methods: The functional genes at the downstream of TWIST1 were obtained via microarray gene expression analyses in the NSCLC cell line. The expression levels of synaptotagmin 7 (SYT7) in a cohort of patients with NSCLC (n = 154) were examined using immunohistochemistry staining and assessed by Kaplan-Meier survival analysis and Cox regression analysis. The effects of SYT7 on the tumorigenesis and metastasis of NSCLC were measured in NSCLC cells. In vivo xenograft lung cancer models were used to study the tumorigenesis role of SYT7.

Findings: We discovered that SYT7 is significantly altered by TWIST1 expression. We further confirmed that SYT7 protein was significantly higher in NSCLC than that in the adjacent normal lung tissue, and higher SYT7 expression was associated with poor survival of NSCLC patients. The protein level of SYT7 was positively correlated with TWIST1 in NSCLC tissue. Functional experiments indicated that SYT7 promoted proliferation, invasion, and metastasis in NSCLC cells in vitro. In vivo experiments showed that shSYT7 inhibited the xenograft tumor growth of NSCLC cells. Knocking down of SYT7 increased the expression of E-cadherin and decreased the level of N-cadherin and Vimentin in cultured cells.

Interpretation: Our data indicate that SYT7 is an important promoter for EMT and tumor progression in NSCLC.

Metastasis remains a serious problem in the management of non-small cell lung cancer (NSCLC). TWIST1 is associated with tumorigenesis and metastasis in NSCLC, while the mechanism of how TWIST1 regulates the occurrence and development of NSCLC remains unclear.

**Added value of this study**

Findings from this study indicate that SYT7 is a critical downstream gene of TWIST1. SYT7 promoted the proliferation, invasion, and metastasis and inhibited cell apoptosis of NSCLC cells through promoting EMT. The repression of SYT7 resulted in the dramatic suppression of tumor growth in vivo. SYT7 might be an independent prognostic marker for the prognosis of NSCLC patients.

**Implications of all the available evidence**

This study provide evidence that SYT7 is a novel oncogene and a diagnostic and a prognostic marker of NSCLC.

2. Materials and methods

2.1. Cell lines and culture conditions

The human NSCLC cell lines H1299, H1975, H358, H125, A549 and human embryonic kidney 293T cells were obtained from Cell Bank, Institute of Life Sciences, Chinese Academy of Sciences Cell Bank (Shanghai, China). These NSCLC cells were cultured in RPMI 1640 medium with 10% fetal bovine serum (FBS) under a humidified atmosphere of 37 °C and 5% of CO₂.

2.2. Plasmid construction and lentivirus transfection experiment

Lentiviral vectors encoding the human TWIST1 and SYT7 gene were purchased from GeneChem (Shanghai, China) for gain-of-function studies. Silencing of target genes was achieved via lentiviral transduction with the following specific shRNA vectors obtained from GeneChem: DUSPS5, TNIP1, TMEM154, CCBE1, CYB5R2, MYEOV, NUAK2, RPS6KL1, PPIF, RIMS2, SYT7, ABHD5, CEP85, LST1, NKF8IE, HVI, POLR3G, SNHG12, UPP1, PKK, TWIST1, and the negative control duplex with a scramble sequence. The transduction processes and the establishment of stable cell lines were executed according to the manufacturer’s instructions. The expressions of the vectors were proved by RT-qPCR and Western blotting. Sequences of the interference targets are listed in Supplementary Table S1.

2.3. Cell migration and invasion assays

The upper chambers of Transwell migration chambers (3422, Corning, NY, USA) were placed at 37 °C for 1 h with serum-free medium. After the removal of the medium, the upper chambers were seeded with serum-starved cells suspensions (1 × 10⁵ cells/well). The 10% FBS was added into the lower chambers. As a reference of invasion, cells suspensions were also seeded into MTS 96-well plate (G3580, Promega, Madison, USA) and OD570 was measured immediately. The cells from the two groups (control group and experimental group) in chambers were incubated at 37 °C for 24 h. After incubation, the medium and the cells remaining on the upper surface of the membrane were removed with cotton swabs. The cells on the lower surface of the membrane were fixed and stained with Giemsa (32884, Sigma-Aldrich, Taußkirchen, Germany), and then photographed under an inverted microscope. Three visual fields were chosen at random and counted per chamber, and the results were analyzed with Image J and calculated by t-test to determine the statistical significance.

The serum-free medium was placed in the lower and upper chambers of invasion chambers (354,480, Corning). After the removal of the medium, the upper chambers were seeded with serum-starved cells suspensions (1 × 10⁵ cells/well). The 10% FBS was added into the lower chambers. As a reference of invasion, cells suspensions were also seeded into MTS plate (Promega) and OD570 was measured immediately. The cells were incubated at 37 °C for 24 h. Cells that had invaded through Matrigel were visualized with Giemsa (Sigma-Aldrich). Three microscopic fields were photographed and counted per chamber, and the data were analyzed via t-test to determine the statistical significance.

2.4. High-Content Screening (HCS) scratch assay

HCS is based on the Cellomics automatic image acquisition and data analysis system. The images were formed by the fluorescence stimulation of targets and the collection of emitted light. The system analyzed the images to acquire the biological events associated with the optical information, including the coordinate position, signal intensity, temporal information, and their combinations. The biological phenomena such as cell quantity, angiogenesis, and apoptosis were then assessed.

Cell culture and transfection were performed as previously described. Cell suspensions of each group were seeded into triplicate wells of 96-well plates. After scratching using a scratch tester, the plates were washed with serum-free medium and incubated in 0.5% FBS. The cells were photographed at 0 h and then incubated at 37 °C and 5% of CO₂. According to the degree of healing, the plates were scanned and the migration distances were analyzed by Cellomics (ArrayScan VT1, Thermo Fisher Scientific).

2.5. Microarray and computational analysis

Total RNA was extracted and purified as described in Supplementary Materials and Methods. All RNAs were labeled using a GeneChip 3′IVT Expression Kit and Hybridization Wash and Stain Kit (Affymetrix, Santa Clara, CA, USA) and analyzed using Affymetrix GeneChip Human Genome U133 plus 2.0 arrays (Affymetrix). The gene expression levels were normalized as log 2 values using GeneSpring software (Agilent Technologies, Palo Alto, CA, USA). Genes that were up- or down-regulated with >1.3 or 2-Fold Change (FC), and a significant difference of P < 0.05 was further subjected to computational simulation by Ingenuity Pathway Analysis (IPA; QIAGEN, Valencia, CA, USA) online tools to perform an enrichment analysis.
2.6. Dual-luciferase reporter assays

Luciferase reporters and expression plasmids were constructed using GeneChem. Cell culture and resuspension of 293T cells were performed as previously described. The cells were seeded into 24-well plates (1 x 10^5 cells/well) and assigned to 4 groups: TWIST1 -Normal Control (NC) + luc-NC; TWIST1-NC + luc-SYT7; TWIST1-OE + luc-NC and TWIST1-OE + luc-SYT7. Plasmids were co-transfected using X-tremeGene HP DNA transfection reagents (06366236001, Roche, Basel, Switzerland). To normalize each transfection reaction, a Renilla reporter plasmid (0.02 μg) was co-transfected with the luciferase reporters (1 μg). The cells were harvested at 48 h post-transfection and lysed, and promoter activity was assayed using the Dual-Luciferase Reporter Assay System (E2910, Promega) on a GloMax 20/20 Luminometer (E5311, Promega) according to the manufacturer’s recommendations.

2.7. Immunohistochemistry

Immunohistochemistry (IHC) was conducted on paraffin-embedded sections. Before staining, paraffin was removed from the slides by incubation at 65 °C for 60 min and treatment with dimethylbenzene two times for 10 min. The tissue sections were then rehydrated by immersion in ethanol-series with descending concentrations (100%, 95%, 80% and 70%) for 5 min each and in deionized water for 2 min, followed by microwave antigen retrieval using citrate. Then endogeneous peroxidase was blocked in 3% H2O2 for 15 min and in 5% H2O2 for 1 min. After that, the slides were incubated in 95%, 80% and 70% for 5 min each and in deionized water for 2 min, followed by microwave antigen retrieval using citrate. Then endogeneous peroxidase was blocked in 3% H2O2 for 15 min and in 5% BSA for 45 min. Afterwards, the slides were incubated overnight at 4 °C with primary rabbit anti-SYT7 antibody (1:100 dilution in PBS, ab121383, polyclonal; Abcam, Cambridge, UK) and anti-TWIST1 antibody (1:200 dilution in PBS, ab50581, polyclonal; Abcam, Cambridge, UK), respectively. After incubation with the second antibody and SABC of HRP conjugated anti-Rabbit IgG SABC Kit (SA1022, BosterBio, Pleasanton, CA, USA) for 30 min each, and chromogen development was performed using a DAB Chromogenic Substrate Kit (AR1022, BosterBio). The slides were stained with hematoxylin and covered with coverslips using neutral balsam. Negative controls were treated with PBS instead of the primary antibody; the other steps remained the same. The paraffin-embedded prostate cancer tissues were used as positive control and treated with the same steps as the NSCLC SYT7 staining.

An intensity score of 0 to 3 was allocated to the intensity of tumor cells (0, none; 1, weak; 2, moderate; and 3, strong). A proportional score was obtained by the estimated proportion of positive tumor cells in percentage. To assess the average degree of staining within a slide, multiple regions were randomly selected and analyzed, and at least 100 tumor cells were assessed. The cytoplasmic expression levels were assessed by the H-score system using the following formula: H-score = Σ(Pi×I) = (percentage of cells of weak intensity × 1) + (percentage of cells of moderate intensity × 2) + (percentage of cells of strong intensity × 3). In the formula, Pi represents the percentage of stained tumor cells and I represents the intensity of staining, producing cytoplasm or nuclear scores ranging from 0 to 300. The H-score above or below the median classified the tumor samples into a high expression group or a low expression group. The scoring was independently assessed by two investigators who were unaware of the clinical outcomes.

2.8. Clinical information and tissue samples

This study was conducted with the approval of the ethical committees of Qilu Hospital of Shandong University (Jinan, China). The patients or their relatives were informed that paraffin sections of resected specimens were used for scientific research. A total of 154 cancer tissue and 136 paracancerous tissue from patients with NSCLC who underwent pneumonectomy were used for the detection of SYT7 and TWIST1 expression by IHC. Clinical information including basic information, pathological type, tumor location, tumor node metastasis (TNM) stage (according to the eighth edition), and prognosis were collected. The overall survival (OS) time was calculated from the surgery date to the end of follow-up or the date of death.

2.9. In vivo tail vein xenograft lung cancer models

All of the surgical procedures and care given to the animals were in accordance with the institutional guidelines. Female BALB/c-nude mice (5 weeks of age) were purchased from Lingchang Biotech (Shanghai, China). A total of 20 nude mice were randomly assigned to a control group and an experimental group, with 10 mice in each group. Luciferase-labeled A549 shControl and A549 shSYT7 cells (2 x 10^6/per mouse) were injected into the tail vein of each nude mouse in two groups, respectively. An in-vivo imaging system (Lumina LT, Perkin Elmer) was used once a week to observe cell vaccination and metastasis in the mice. The tumor-bearing mice were sacrificed 38 days after inoculation. Tumor volume was calculated as follows: V (volume) = (length × width^2)/2. The tumors were harvested and frozen at −80 °C at the end of the experiments for our next studies. All of the animal procedures were approved by the Ethics Committee of Qilu Hospital of Shandong University (KYLL-2013-097; February 25, 2014).

2.10. Bioinformatics analysis

RNA-Seq microarray gene expressions of TWIST1 and SYT7 in 21 NSCLC cell lines (LK2, NCIH1155, NCIH1755, NCIH2106, NCIH1693, NCIH522, SCLC21H, A427, NCIH520, NCIH23, NCIH1650, CORL47, EPLC272H, NCIH2444, NCIH2009, HCC95, NCIH2085, RERFC57Q1, NCIH322, NCIH1573, HCC1711) were downloaded from Cancer Cell Line Encyclopedia (CCLE) [27]. Robust Multi-array Average (RMA) normalization was performed. Correlation between TWIST1 and SYT7 expression was analyzed by Spearman's rank correlation test.

The differential expression of SYT7 between lung adenocarcinoma (LUAD) and normal lung tissues, as well as lung squamous cell carcinoma (LUSC) and normal lung tissues, were verified using TCGA data by GEPIA online analysis tool (http://gepia.cancer-pku.cn/) [28]. The following settings were used for the expression analysis: ‘Boxplot’; ‘Gene = SYT7’; ‘|Log2FC| Cutoff = 1’; ‘P-value Cutoff = 0.01’; ‘Datasets = LUSC, LUAD’; ‘Log Scale = Yes’; ‘Jitter Size = 0.4’; and ‘Match TCGA normal data’. The relationship of SYT7 and TWIST1 mRNA expression in NSCLC was also analyzed using GEPIA by Pearson’s correlation analyses. The following settings were used for the correlation analyses: ‘Correlation’; ‘Gene A = SYT7’; ‘Gene B = TWIST1’; ‘Correlation Coefficient = Spearman’; ‘Datasets = TCGA Tumor, TCGA Normal’.

The correlation of individual SYT7 mRNA expression with OS was analyzed using an online database [29] that was established using gene expression data and survival information of lung cancer patients and downloaded from the Gene Expression Omnibus (GEO). SYT7 was entered into the database called the Kaplan-Meier (K-M) Plotter (http://kmplot.com/analysis/index.php?p=service&cancer=lung) to obtain KM survival plots. The mRNA expression of SYT7 above or below the median classified the cases into a high expression group and a low expression group, respectively. These cohorts were compared with a Kaplan-Meier survival plot. Hazard ratios (HR), 95% confidence intervals (CIs), and log-rank P values were determined and displayed on the webpage.

2.11. Statistical analysis

The quantitative data are shown as the mean ± standard deviation (SD). The significance of a difference between the groups was tested using Student’s t-test for the data from the cell and animal experiments. Mann-Whitney U test was used for comparison between two groups not normally distributed having quantitative variables. Correlation between the TWIST1 and SYT7 protein levels in NSCLC patient tissue was analyzed by chi-square (χ^2) test, with R representing the correlation coefficient. The clinical variables between the groups were
compared using the χ² test. OS was calculated from the data from the lung cancer diagnosis to death from any cause or was censored at the last follow-up data. The OS rate was analyzed using Kaplan-Meier method with the log-rank test. The Univariate Cox regression proportional hazards model was performed to estimate the effect on OS. The variables with a P-value < .1 in the univariate analysis were further analyzed by a multivariate analysis of the prognostic factors. All of the analyses were performed using SPSS 21.0 software (IBM Corporation, Armonk, NY, USA). Differences with a P-value < .05 were considered statistically significant. More information about the methods, including the real-time quantitative reverse transcription PCR (RT-qPCR), Western blotting, scratch assay, and the cell proliferation and apoptosis assays is provided in the Supplementary Materials and Methods.

3. Results

3.1. Establishment of TWIST1-OE H1975 cells

With H1975 cells showing a low TWIST1 transcript level in comparison with three other cell lines, (H1299, A549, and H358) (Fig. 1a), we ectopically expressed TWIST1 in H1975 cells using the lentivirus expression system. >80% of the cells had fluorescent protein expression 72 h after virus infection. We confirmed higher levels of TWIST1 transcript and TWIST1 protein in TWIST1-OE H1975 cells (Fig. 1b and c). Next, we performed cell migration experiments on the TWIST1-OE H1975 cells, and found them to be more aggressive than the cells expressing only the empty vector (Fig. 1d). Similarly, the TWIST1-OE H1975 cells were more invasive than the control cells in a transwell migration assay (Fig. 1e).

3.2. Expression of SYT7 was significantly altered by TWIST1 in the microarray analysis and HCS experiments

To explore the downstream genes of TWIST1 in NSCLC cells, we used the TWIST1-OE H1975 cells and control-H1975 cells for a whole genome expression profiling microarray analysis. A total of 1297 differentially expressed genes (DEGs) were identified, with 589 DEGs upregulated and 708 DEGs downregulated (Fig. 2a–b, Table S2). Pathway enrichment analysis showed that these DEGs were primarily involved in the following signaling pathways: TNF pathway, NF-κB pathway, MAPK pathway, PI3K/AKT pathway, p53 pathway, Hippo pathway, JAK/STAT regulatory pathway, and so on (Table S3 and Fig. S1). We selected 28 significant DEGs through a literature search and pathway analysis. They were relatively novel molecules and had the potential to regulate lung cancer. We validated these 28 DEGs using RT-qPCR, and found a total of 20 highly expressed DEGs in TWIST1-OE H1975 cells (Table S4).

Next, we constructed 3 RNA interference (RNAi) targets for each gene and used a mixture of 3 plasmids for each gene in equal ratios for lentiviral packaging. As shown in Fig. 2c–d, HCS experiments in TWIST1-OE H1975 cells showed that the most significant disruption of cell migration was from SYT7 gene knockdown (0.12, P < .05 in comparison with the control group, and Student’s t-test) and CEP85 gene knockdown (0.35, P < .05 in comparison with the control group, and Student’s t-test). The suppression of cell migration by SYT7 and CEP85 gene knockdown was also demonstrated in A549 cells (0.28, P < .05; 0.57, P < .05, respectively; Student’s t-test, Fig. 2e). We further validated the effects using the TWIST1-OE H1975 cells expressing a single shRNA for each gene (with three separate shRNAs for each gene). The results showed that each shRNA was sufficient to inhibit cell migration, further confirming that SYT7 and CEP85 promote cell migration in the TWIST1-OE H1975 cells (Fig. 2f). Of the two genes, the knockdown of SYT7 inhibited cell migration more strongly, so we chose SYT7 for the following functional study.

To further confirm whether TWIST1 can regulate the mRNA expression of SYT7, knockdown of TWIST1 was performed via lentiviral transduction with shTWIST1 vectors. In A549 and H1299 cells, we analyzed the relative mRNA expression of SYT7 in the shTWIST1 and shCtrl cells, respectively. The results showed that SYT7 was significantly downregulated after the knockdown of TWIST1 (P < .001, Student’s t-test, Fig. S2a).

3.3. Association of SYT7 expression with TWIST1 and the clinicopathological parameters of NSCLC

The relevance of our studies was evaluated in NSCLC lung tissues form human specimens. We detected the expressions and subcellular
localization of SYT7 and TWIST1 protein by IHC in NSCLC tissues (N = 154) and adjacent normal tissues (N = 136) of patients (Fig. 3a–j). Positive SYT7 staining was mainly detected in cellular membrane and cytoplasm in NSCLC tissues (Fig. 3c–d and 3g–h). The expressions of SYT7 protein in the tumor tissues of LUAD (n = 86) and LUSC (n = 68) patients were significantly higher than in the adjacent normal tissues, respectively (P < .01, Mann-Whitney U test, Fig. 3l). To confirm the association between SYT7 and TWIST1 protein expression in NSCLC patients, we also performed IHC staining of TWIST1 in those 154 NSCLC tissues. Positive TWIST1 staining was mainly detected in the cell nucleus and cytoplasm in NSCLC (Fig. 3e–f, i–j). The correlation between the SYT7 and TWIST1 protein levels was significantly positive (P < .001, R = 0.403, Pearson’s χ² test). Overall, 70.1% (54 of 77) of the tumor samples exhibited the same staining intensity of TWIST1 and SYT7 protein (Fig. 3k).

To validate the correlation between TWIST1 and SYT7 mRNA expression, we performed Spearman’s correlation analysis of TWIST1 and SYT7 mRNA expression (RNASeq) in 21 NSCLC cell lines on CCLE. There was a significantly positive correlation between TWIST1 and SYT7 mRNA expression (P < .05, R = 0.508, Spearman’s rank correlation test, Fig. S2b). Correlation analyses in clinical LUAD and LUSC of TCGA were also analyzed, showing a positive correlation between SYT7 and TWIST1 expression in the LUSC tumor and normal samples (P < .001, R = 0.35, Spearman’s rank correlation test, Fig. S2c).
Fig. 3. The expression and correlation of SYT7 and TWIST1 in NSCLC tissue determined by IHC and survival analyses and the expression of SYT7 in NSCLC cell lines. a and b, Negative SYT7 protein expression in the normal tissues adjacent to the non-cancerous tissue samples. c, Low expression of SYT7 protein in the adenocarcinoma tissues. d, Low expression of SYT7 protein in the squamous cell carcinoma tissues. e and f, Expression of TWIST1 protein in the tumor tissue shown in c and d, respectively. g, High expression of SYT7 protein in the adenocarcinoma tissues. h, High expression of SYT7 protein in the squamous cell carcinoma tissues. i and j, Expression of TWIST1 protein in the tumor tissue shown in g and h, respectively. a-j were ×400 magnification (scale bar = 50 μm). k, Correlation between TWIST1 and SYT7 protein levels in NSCLC (P \( < \) 0.001, R = 0.403, Pearson’s \( \chi^2 \) test). l, Semiquantitative analyses of the SYT7 protein expression in the NSCLC and normal tissues adjacent to the non-cancerous tissue samples (\( \times \) 100, \( \times \) 50, \( \times \) 100, Mann-Whitney U test). m, The mRNA expression levels of SYT7 in four NSCLC cell lines Twist1-OE H1975, H125, A549, and H1299. n, Kaplan-Meier survival curves indicated that the protein expression of SYT7 was significantly associated with the OS rate of the clinical LUAD and LUSC patients (Kaplan-Meier method with log-rank test). o, SYT7 was highly expressed in LUAD and LUSC compared with normal lung tissue in the TCGA database (\( P \leq 0.05 \), one-way ANOVA test). p, The OS was lower in the patients with a high expression of SYT7 than in those with a low expression of SYT7 in all of the NSCLC patients in the K-M Plotter database (Kaplan-Meier method with log-rank test). q and r, OS was lower in the patients with a high expression of SYT7 than in those with low expression of SYT7 in LUAD and LUSC patients in the K-M Plotter database (Kaplan-Meier method with log-rank test). The data in i and n are expressed as mean values ± SEM (n = 3).
The mRNA expression of SYT7 in four cell lines (A549, H1299, TWIST1-OE H1975 and H125) were detected by RT-qPCR. As shown in Fig. 3m, SYT7 was highly expressed in the TWIST1-OE H1975 cells and moderately expressed in the other three lung cancer cells. The association between SYT7 protein expression and clinicopathological variables of the LUAD and LUSC patients is summarized in Table 1. In the LUAD patients, the high expression of SYT7 was significantly associated with gender (P = .03, Pearson's χ² test), differentiation grade (P = .033, Pearson's χ² test), and TNM stage (P = .03, Pearson's χ² test). In the LUSC patients, there was no association between SYT7 and the clinicopathological variables (P > .05, respectively, Pearson's χ² test).

The univariate and multivariate analyses of prognostic variables for the survival rate of LUAD and LUSC are shown in Table 2. In the LUAD patients, univariate Cox regression analyses revealed that the overexpression of SYT7 (HR 1.920, 95% CI 1.158–3.186, P = .012) was a significant negative prognostic factor for OS. Multivariate analysis showed that SYT7 overexpression remained an independent prognostic factor (HR 1.823, 95% CI 1.009–3.292, P = .046) of OS after adjusting for TNM stage, lymph node metastasis, and gender. The Kaplan–Meier survival curves confirmed that OS was negatively associated with high SYT7 protein expression (P < .01, log-rank test, Fig. 3n).

In the LUSC patients, univariate Cox regression analyses suggested that the overexpression of SYT7 (HR 2.067, 95% CI 1.020–4.188, P = .044) was a significant negative prognostic factor for OS. Multivariate analysis showed that SYT7 overexpression remained the independent prognostic factor (HR 2.329, 95% CI 1.132–4.788, P = .022) after adjusting age at diagnosis and TNM stage. The Kaplan–Meier survival curves also confirmed that the OS of the LUSC patients gradually declined with the increasing SYT7 expression (P < .05, log-rank test, Fig. 3n).

### 3.4. Differential expression of SYT7 mRNA in the TCGA database and survival analysis in the K-M Plotter database

The data of SYT7 mRNA expression, which contained 483 cases of LUAD, 486 cases of LUSC, and 59 cases of normal lung tissues, were obtained from the TCGA database for analyses using the GEPIA online tool. As shown in Fig. 3o, SYT7 was highly expressed in both LUAD and LUSC compared with normal lung tissue, respectively (P < .05, one-way ANOVA).

The association of SYT7 mRNA expression with prognosis was evaluated using the K-M Plotter database. From a total of 1926 NSCLC patients, poor OS was associated high expression of SYT7 (HR = 1.26, P < .01, Kaplan-Meier, and the log-rank test; Fig. 3p). For the LUAD patients (n = 720), poor OS was also associated with high expression of SYT7 (HR = 1.64, P < .001, Kaplan-Meier, and the log-rank test; Fig. 3q). A similar result was observed in the LUSC patients (n = 524) (HR = 1.6, P < .01, Kaplan-Meier and log-rank test; Fig. 3r). These data suggest that the high expression of SYT7 indicated a poor prognosis for the NSCLC patients, which is in accordance with our clinical prognosis analyses.

### 3.5. Knockdown of SYT7 inhibited metastasis, invasion, proliferation, and markers of EMT and increased apoptosis in vitro

To evaluate the impact of SYT7 on the invasion and metastasis of the NSCLC cell lines, the TWIST1-OE H1975 cells, H1299 cells, and A549 cells were infected with shCtrl and shSYT7 lentivirus, respectively. After shSYT7 lentivirus infection, the expression levels of SYT7 mRNA were significantly decreased in the shSYT7 group of TWIST1-OE H1975 cells, H1299 cells, and A549 cells. The knockdown efficiency reached 38%, 50.1%, and 39.9%, respectively (all P < .05, Student's t-test; Fig. 4a–c). The expressions of SYT7 protein also significantly decreased in these three cell lines (Fig. 4d).

In the TWIST1-OE H1975 cells, the transwell migration and invasion experiments showed that shSYT7 significantly inhibited migration and invasion (P < .001, Student's t-test; Fig. 4e). Similar results were also observed in A549 and H1299 cells following shSYT7 expression (P < .001 and P < .01, respectively, Student's t-test; Fig. 4f and g). To evaluate the effect of SYT7 on the proliferation and apoptosis of NSCLC, an MTT proliferation assay and FACS apoptosis assay were performed in A549 and H1299 cells. We found that shSYT7 expression also reduced cell proliferation (to obtain the exact number in the results plus the P-values) (P < .001, Student's t-test; Fig. 5a), suggesting that SYT7 had a significant effect on the proliferation of A549 and H1299 cells. When compared with the shCtrl group, the apoptotic rates of A549 and H1299 cells in the shSYT7 group significantly increased (P < .01, Student's t-test; Fig. 5b).

### Table 1

| Clinicopathologic characteristic | SYT7 expression | n Low expression | High expression | Pearson χ² | P |
|----------------------------------|-----------------|------------------|-----------------|------------|---|

LUAD: lung adenocarcinoma; LUSC: lung squamous cell carcinoma; TNM: tumor node metastasis.

* P < .05, χ² test.

A difference in expression was only seen in T2 tumor while T1 and T3 had the same percentage of staining.
suggesting that the knockout of SYT7 significantly increased apoptosis in A549 and H1299 cells. Using a colony formation assay, the numbers of colony cells in the shSYT7 group significantly declined compared with the shCtrl group ($P < .01$, Student’s t-test; Fig. 5c).

We further detected the expression of EMT-related markers in the shCtrl and shSYT7 group of the H1299 cells (Fig. 5d). The results showed that the expression of E-cadherin was significantly increased after the knockdown of SYT7. Meanwhile, the expressions of N-cadherin and Vimentin were significantly decreased in comparison with the tumors formed by the A549-shCtrl cells ($P < .05$, Student’s t-test; Fig. 6a). The decrease in the size and weight of the tumors formed by the A549-shSYT7 group was monitored and quantitatively measured using an non-invasive bioluminescence system. The results showed that the amount of fluorescence expression in the shSYT7 group significantly decreased compared with the shCtrl group ($P < .05$, Student’s t-test; Fig. 6a). The size and weight of the tumors formed by the A549-shSYT7 cells significantly decreased in comparison with the tumors formed by the A549-shCtrl cells (Fig. 6b-Hi). The dissected lung tissues of the nude mice were further observed in the shCtrl group, there were signs of metastasis in the lungs of 10 mice, and 155 metastases were found. Meanwhile, only 1 lung cancer cell metastasis in 1 mouse of in the shSYT7 group was found. We performed Western blotting to detect the protein expression of SYT7 in the lung tumor tissues, showing significantly decreased SYT7 protein levels in the shSYT7 group compared with the shCtrl group (Fig. 5d). Taken together, these results indicated that the knockdown was significantly elevated in the SYT7-OE cells of A549 and H1299 cells ($P < .001$, Student’s t-test; Fig. 6e).

3.7. Knockdown of SYT7 inhibited tumorigenesis in vivo

To determine the effect of SYT7 on NSCLC cells tumorigenesis in vivo, we performed an experimental model of nude mice tail vein inoculation tumorigenicity. At 2 days, 10 days, 20 days, 24 days, 31 days, and 38 days after inoculation of A549 cells, the lung colonization of these cells in the A549-shCtrl and A549-shSYT7 groups was monitored and quantitatively measured using a non-invasive bioluminescence system. The results showed that the amount of fluorescence expression in the shSYT7 group significantly reduced compared with the shCtrl group ($P < .05$, Student’s t-test; Fig. 6a). The lung tissues of the sacrificed mice then underwent in vivo imaging, and the fluorescent expression in the lungs of the shSYT7-mice was also significantly reduced compared with the shCtrl group ($P < .05$, Student’s t-test; Fig. 6a). The size and weight of the tumors formed by the A549-shSYT7 cells significantly decreased in comparison with the tumors formed by the A549-shCtrl cells (Fig. 6b-Hi). The dissected lung tissues of the nude mice were further observed in the shCtrl group, there were signs of metastasis in the lungs of 10 mice, and 155 metastases were found. Meanwhile, only 1 lung cancer cell metastasis in 1 mouse of in the shSYT7 group was found. We performed Western blotting to detect the protein expression of SYT7 in the lung tumor tissues, showing significantly decreased SYT7 protein levels in the shSYT7 group compared with the shCtrl group (Fig. 5d). Taken together, these results indicated that the knockdown
of SYT7 significantly inhibited the tumor growth of the lung cancer cells in vivo.

3.8. The regulation function of TWIST1 on SYT7

To confirm whether TWIST1 acts as a transcription factor to directly regulate the expression of SYT7, we performed a Dual-luciferase reporter gene assay. As shown in Fig. S2e, the TWIST1-OE cells that were transfected with SYT7 recombinant promoter plasmid showed no significant difference in fluorescence signal intensity compared with the negative control group (P > 0.05, Student’s t-test). This suggested that TWIST1 and SYT7 promoter could not directly bind, indicating that the regulation of SYT7 expression by TWIST1 may be not through direct transcriptional regulation.

4. Discussion

In this study, we identified SYT7 as the downstream gene of TWIST1 in NSCLC cells. The knockdown of SYT7 weakened the metastasis and invasion abilities of the TWIST1-OE H1975 cells. SYT7 was highly expressed in both NSCLC cell lines and clinical tissues and demonstrated to be correlated with a poor OS rate in NSCLC patients. The protein level of SYT7 was positively correlated with TWIST1 in the clinical NSCLC tissues. Moreover, loss-of-function and gain-of-function analyses revealed that SYT7 promoted the proliferation, EMT, invasion, and metastasis and inhibits cell apoptosis of the NSCLC cells. The knockdown of SYT7 significantly inhibited tumor promotion role of lung cancer cells in vivo. These results emphasize the potential tumor promotion role of SYT7 in NSCLC.

TWIST1 belongs to a family of basic helix-loop-helix proteins that function as transcription factors [30]. It has been reported that TWIST1 mediates tumorigenesis, metastasis, EMT, and drug resistance in NSCLC, demonstrating its potential as a drug target [14–16,31–35]. Our results showed that the overexpression of TWIST1 enhanced the invasion and metastasis abilities of the NSCLC cells, which was in accordance with previous studies reporting that TWIST1 was recognized as a critical regulator of metastasis in NSCLC [32]. To further seek novel genes related to the invasion and metastasis of NSCLC, we found that SYT7 and CEP85 were the functional genes at the downstream of TWIST1 through gene chip and HCS method. Functional experiments of SYT7 and CEP85 were then conducted in sequence, and the SYT7 results were exhibited in this study.

SYT7, a member of the synaptic binding protein gene family, is required for facilitation of the central synapses as the specialized Ca^{2+} sensor [36–39]. SYT7 regulates the chemokine-induced fusion of lysosomes with the cell membrane in migrating cells, and the SYT7-deficient leukocytes showed less migration in vitro and in vivo [40]. As the calcium sensor involved in the lysosome-mediated repair mechanism of plasma membrane, SYT7 transcription is induced by prostaglandin E(2) [41]. A recent study indicated that SYT7 is associated with hepatic metastasis formation of gastric cancer cells [42]. It was also reported that SYT7 was overexpressed in colorectal cancer and regulated the proliferation colorectal cancer cells [43]. However, the detailed function and underlying mechanism of SYT7 in lung cancer tumorigenicity and metastasis remain unknown. Our study found the
involvement of SYT7 in the proliferation and metastasis of NSCLC, which is consistent with its function in gastrointestinal tumors research. The knockdown and overexpression experiments demonstrated the promotion function of SYT7 in NSCLC cells proliferation, migration, and invasion in vitro. Furthermore, the repression of SYT7 inhibited the tumorigenicity and tumor growth of the NSCLC cells in vivo. However, the underlying causes of tumorigenic and promoting metastasis effects of SYT7 have not been reported. Hence, we explored the molecular mechanism of SYT7 in NSCLC.

We demonstrated that SYT7 may promote tumorigenesis and metastasis through activating EMT, an essential process during cancer metastasis and progression. After the knockdown of SYT7, the expression of E-cadherin significantly increased, and the expression of N-cadherin and Vimentin significantly reduced. We also demonstrated the upregulation of SYT7 protein in the tumor tissue of the NSCLC patients. The protein expression of SYT7 was positively correlated with TWIST1 in the NSCLC patients. In both the LUAD and LUSC tissues, higher SYT7 expression was significantly associated with inferior survival independently of conventional prognostic factors, which further confirmed that the upregulation of SYT7 promoted NSCLC development. Survival outcomes vary among NSCLC patients, even within groups that present with the same stage at the time of diagnosis and are treated with similar strategies [44,45]. Hence, it is necessary to develop accurate prognostic factors. In recent studies, emerging novel prognostic biomarkers were reported and showed promising efficacy in NSCLC patients, such as estrogen receptor β [46], regulatory T cells [47], and tripartite motif-containing 37 [48]. In our study, the upregulation of SYT7 demonstrated the potential to predict poor prognosis of NSCLC patients.

Some limitations to our study must be acknowledged. First, we investigated the functional mechanism between TWIST1 and SYT7. However, the dual-luciferase reporter assay result suggested that the regulation of SYT7 expression by TWIST1 is not through the direct transcriptional regulation. The molecular mechanism of the interaction between SYT7 and TWIST1 has not been clarified. Second, the in-depth mechanism of SYT7 involved in the development and progression of NSCLC must be revealed. In the future, large-scale prospective researches are necessary to further assess the values of SYT7 in the diagnosis and predicting the prognosis of NSCLC, and the underlying biological mechanism of SYT7 will be illustrated in our future research.

In summary, our study suggested that SYT7, as the downstream gene of TWIST1, plays a potential tumor promotion role in NSCLC. We observed that SYT7 protein was highly expressed in NSCLC tissue, and was an independent prognostic marker for patient survival. The results of the knockdown and overexpression experiments revealed that SYT7 promotes the proliferation, invasion, and metastasis and inhibited cell apoptosis of NSCLC in vitro. These functions may be generated through promoting EMT. In vivo, the repression of SYT7 resulted in the dramatic
suppression of tumor growth, which could be a vigorous therapeutic strategy for future NSCLC treatment.
