We study the quantum fidelity (groundstate overlap) near quantum phase transitions of the Ising universality class in one dimensional (1D) systems of finite size L. Prominent examples occur in magnetic systems (e.g. spin-Peierls, the anisotropic XY model), and in 1D topological insulators of any topologically nontrivial Altland-Zirnbauer-Kitaev universality class. The rescaled fidelity susceptibility is a function of the only dimensionless parameter \(LM\), where \(2M\) is the gap in the fermionic spectrum. We present analytic expressions for the fidelity susceptibility for periodic and open boundaries conditions with zero, one or two edgestates. The latter are shown to have a crucial impact and alter the susceptibility both quantitatively and qualitatively. We support our analytical solutions with numerical data.

Introduction. P. W. Anderson’s remarkable discovery of the orthogonality catastrophe \cite{Anderson} states that the overlap of two many-body groundstates of two different Hamiltonians, which differ by only a small perturbation, vanishes in the thermodynamic limit: a phenomenon which has recently attracted renewed interest in the expanding research field of quantum information theory. This branch of quantum physics, which is devoted to the information stored in the wave functions, provides an intriguing arena for both fundamental and applied studies. While one major driving force is the search for a quantum computer, the quantities of interest in quantum information theory, by themselves mathematically fascinating objects, turned out to be useful tools \cite{NielsenChuang} in the investigation of fundamental phenomena in condensed matter physics, such as quantum phase transitions (QPTs) \cite{QPT} and topological phases of matter (TPM) \cite{TPM}.

Quantum phase transitions in 1D. By definition, a QPT separates two fundamentally different groundstates in the space of externally controllable parameters. Often this ‘fundamental difference’ is the (broken) symmetry of the state. However, the recent advent of TPM lead to the reexamination of this paradigm: here the ‘fundamental difference’ follows from the topological index of the ground state and manifests itself in the appearance of gapless boundary states. In general, a connection between the two concepts of spontaneous symmetry breaking and symmetry protected topological order \cite{SW} is not known. However, in one spatial dimension, several archetypical models for QPTs and for TPM are well known to be dual to each other, see Table \ref{tab:dualities}.

For noninteracting fermions, transitions between distinct TPM are accompanied by a gap closing \cite{gapclosing}. Therefore, the minimal model for such transitions, i.e. the 1D Dirac Hamiltonian

\[
H = p \tau_x + m \tau_z ,
\]

turns out to be the universal low-energy theory for topological phase transitions in 1D lattice models of all Altland-Zirnbauer-Kitaev universality classes \cite{U1,U2}. In Eq. \ref{eq:dirachamiltonian} \(p\) is the momentum operator and \(m\) the mass with \(\tau_x,\tau_y,\tau_z\) Pauli matrices. Close to criticality the Dirac Hamiltonian is the low energy theory for Ising transitions in two space-time dimensions \cite{U1,U2}.

Fidelity and fidelity susceptibility. In this paper we investigate the behavior of the groundstate overlap (or quantum fidelity) near QPTs of the Ising universality class in 1D systems of finite size \(L\) and particularly scrutinize the impact of edge states \cite{ES}. The fidelity is defined as

\[
\mathcal{F} = | \langle \Psi_{0,-} | \Psi_{0,+} \rangle | ,
\]

where \(|\Psi_{0,\pm}\rangle\) is the many body groundstate to Eq. \ref{eq:dirachamiltonian} with mass \(m = -M \mp \delta M/2\). In the limit \(|\delta ML| \gg 1\), \(\mathcal{F}\) decays \cite{Anderson} at least as a power law, while in the limit \(|\delta ML| \ll 1\) it can be expanded (we will focus on dimension \(d = 1\)) as

\[
\mathcal{F} \approx 1 - \frac{(\delta M)^2 L^d}{2} \chi_F .
\]
In abstract quantum information theory, the wave function overlap, Eq. (2), is related to the Fubini-Study distance $d_{FS}(\langle \Psi_0^- | \Psi_0^+ \rangle)$ between elements of the Hilbert space. In contrast, the fidelity susceptibility is related to the Fisher information metric which essentially pulls back the quantum distance $d_{FS}$ to the space of parameters entering the Hamiltonian. It can be related to the real part of the quantum geometric tensor [19–21].

The experimental relevance of the wave function overlap includes numerous physical systems and phenomena such as the Mößbauer effect, X-ray spectroscopy and Kondo physics both in solid state and cold atomic setups. The relationship between the fidelity and the structure factor [22], imaginary time correlation functions [20], the probability of excitation after a sudden quench [23], the scattering matrix [24] and the spectral function [25], were uncovered in recent studies. Furthermore, the wave function overlap was shown to enter several observables, such as the average magnetization, for an Ising chain in the continuum model, these two cases translate to the SSH model with an even $\delta$ or $\delta$, where the upper (lower) sign refers to PBC (ABC). These two results are plotted as a blue dot-dashed and a green dotted curve in Fig. 1.

**Open boundary conditions.** We now consider the situation of open boundary conditions, which for Dirac fermions are modelled by means of a “potential well” in the mass $m(x)$ entering Eq. (1). We consider two different boundary conditions and introduce them by means of the Su-Schrieffer-Heeger (SSH) lattice model:

$$H_{SSH} = -t \sum_{j=1}^{N-1} \left[ (1 + (-1)^j \delta) (c_j^\dagger c_{j+1} + H.c.) \right].$$

Here $t(1 \pm \delta)$ is the dimerized hopping between sites $N$ and $c_j^\dagger$ creates a fermion at site $j$. In the vicinity of criticality ($\delta \to 0$, $N \to \infty$), the continuum theory of Eq. (6) is given by Eq. (1) with the identification $-m = M = \delta/a$, where $a$ is the lattice constant and we set the speed of “light” $v = 2ta/h = 1$. The chain with an even number of sites $N$ is topologically nontrivial (hosts one edge state per boundary) when $\delta > 1/(1 + N)$ and is topologically trivial when $\delta < 1/(1 + N)$. In contrast, the chain with an odd number of sites always contains a zero mode which, depending on the sign of $\delta$, is localized on the left or right end of the system.

In the continuum model, these two cases translate to the boundary conditions as follows. Due to the finite system size the wave function has support only in one of the two sublattices. Therefore, one of the two pseudospin projections of the Dirac-spinors vanishes at the system’s boundary. We impose this constraint by the following spatial dependence of the mass profile, see Fig. 2.

$$m(x) = \begin{cases} M_\infty, & x < -L/2, \\ -M_\infty, & -L/2 < x < L/2, \\ \pm M_\infty, & L/2 < x. \end{cases}$$

The limit $M_\infty \to \infty$ is to be understood and we refer to the boundary conditions implied by the upper (lower) sign as symmetric (asymmetric). These two general boundary conditions exhaust the possibilities for the open 1D Dirac model. In the symmetric case, which corresponds to the SSH model with an even $N$, edge states

| 1D XY magnet | ⇔ | 1D fermions |
|-------------|---|--------------|
| mean coupling $J_x + J_y$ | ⇔ | hopping $t$ |
| anisotropy $J_x - J_y$ | ⇔ | p-wave pairing $\Delta$ |
| transverse magnetic field $h$ | ⇔ | chemical potential $\mu$ |
| staggered coupling $\delta$ | ⇔ | staggered hopping $\delta$ |

$\mathbb{Z}_2$ symmetry | ⇔ | fermion parity |
| magnetic order | ⇔ | SPT order |

TABLE I: Comparison of 1D magnetic and fermionic models. In the Kitaev chain (i.e. the anisotropic XY model) $\delta = 0$ while in the SSH and spin Peierls models $J_x - J_y = 0 = h$. For more details, see the main text and Refs. 7 [8] [32] [33].
appear for $ML > 1$ and are absent otherwise. In contrast, the Callias-Bott-Seeley theorem \cite{34, 35} implies the presence of a zero energy state for any value of $ML$ with the asymmetric boundary conditions, as found in the SSH model with an odd $N$.

The fidelity susceptibility for the asymmetric mass profile turns out to be independent on whether the Fermi energy is chosen infinitesimally positive or infinitesimally negative. This is a consequence of the chiral symmetry (or, equivalently, of the particle-hole symmetry) \cite{18, 33}. Therefore, the edge state formally does not contribute to the fidelity susceptibility, and the result is

$$f_{\chi F}(ML) = \frac{ML \left[ \coth(ML) - 2ML \text{csch}^2(ML) \right] + 1}{16(ML)^2}.$$  

The fidelity susceptibility for the asymmetric boundary conditions is plotted red, dashed in Fig. 1.

Finally, we consider the symmetric mass profile. The fidelity susceptibility in this case is determined by the overlap of kinetic energy and rest mass is small. The summand is determined by the overlap of single particle states, which is more susceptible when the ratio between kinetic energy and rest mass is small. The smallest nonzero wavevector for PBC is larger than the smallest wavevector in all other cases, see Ref. \cite{33}.

$\text{FIG. 2:}$ Open boundary conditions for the 1D Dirac model: the asymmetric (left; red, dashed) and symmetric (right; black, solid) mass profile corresponds to, e.g., an SSH chain with odd and even $N$, respectively. The nondispersive wave functions $\psi_b(x)$ (purple) are localized at a single edge for the asymmetric mass profile, while they have equal weight on either boundary in the symmetric case. In the latter case, only the edge state with odd parity contributes to the groundstate fidelity. In this plot $ML = 10$.

For all boundary conditions, the fidelity susceptibility can be represented as a sum over nonzero wavevectors. In the present case ($dv < 2$) the sums are ultraviolet convergent and dominated by the infrared. This is because the summand is determined by the overlap of single particle states, which is more susceptible when the ratio between kinetic energy and rest mass is small. The smallest nonzero wavevector for PBC is larger than the smallest wavevector in all other cases, see Ref. \cite{33}.

It is noteworthy, how accurately the fidelity for ABC interpolates between the functions for PBC ($|ML| \gtrsim 5$) and the model with asymmetric mass profile ($|ML| \lesssim 5$). The duality of phases for $M > 0$ and $M < 0$ implies that in these three cases $f_{\chi F}(ML)$ is symmetric and peaked at zero, the location of the phase transition. In contrast, for open symmetric boundary conditions, there is no such duality and the reduced fidelity susceptibility is maximal at

$$M = M_{c,\chi F} \equiv b_{\chi F}/L^\lambda,$$

with $b_{\chi F} \approx 1.8$ and $\lambda = 1/\nu = 1$ (the shift exponent). For all four cases, Eq. (10) implies a bulk-dominated fidelity susceptibility as long as $(c_{\chi F}$ of order unity)

$$|M| \gtrsim c_{\chi F}/L^\theta.$$  

In the Ising universality class, the rounding exponent is $\theta = 1/\nu = 1$. While our result for the exponents $\lambda$ and $\theta$ conform with the finite size scaling theory of thermodynamic quantities \cite{38, 69} the value of $b_{\chi F}$ is remarkable inasmuch as other observables, such as the groundstate energy \cite{31} suggest $M_e = 1/L \leq M_{e,\chi F}$ for the transition point. As we noted above, $M = M_e$ is the point in parameter space beyond which nondispersive edge states exist. In contrast, at $M \sim M_{c,\chi F}$ the two edge states decouple, i.e. their decay length becomes comparable to the
system size. One should keep in mind that, formally, phase transitions are defined in the thermodynamic limit, in which both \( M_{e,\chi_F} \) and \( M_e \) approach zero.

A physical intuition for the fidelity susceptibility can be developed on the basis of the groundstate for closed boundary conditions, which is the product state over a collection of two-level systems. At opposite sides of the transitions, the “pseudo-spins” tend to be oriented in opposite directions depending on the sign of the mass. Close to the transition the applied “field” is weak and thus the “pseudo-spins” are more susceptible to changes in the “field” and the fidelity smaller \( (\chi_F \text{ larger}) \). Similarly, boundary constraints which are more invasive than PBC generally lead to decoherence of the spin polarization and therefore the fidelity susceptibility is larger. For the symmetric mass profile, however, one should address the two sides of the transition separately. Open boundary conditions imply a node in the dispersing wave functions at the end of, e.g., the SSH chain. Therefore, at the boundary, the form of the wave function is nearly independent of the dimerization and on the topologically trivial side the fidelity in an open system is larger than for PBC. In contrast, on the nontrivial side, the boundary contribution is strongly influenced by edge states. These are susceptible to changes in the dimerization and therefore the boundary contribution to \( \chi_F \) is positive. This behavior is reflected in the asymptotes, Eq. (10).

**Conclusion and outlook.** In this article we derived and discussed the scaling function for the fidelity susceptibility in finite systems close to 1D Ising QPTs. To this end, we employed the critical continuum theory of 1D Dirac fermions subjected to four different types of boundary conditions: open boundary conditions allowing for one or two subgap states as well as periodic and antiperiodic boundary conditions. The fidelity susceptibility close to the transition is smallest for PBC, i.e. in the case of the putatively least invasive constraint. The situation when the boundary conditions allow for two subgap states strongly differs from all others: Only in this case are the two phases not dual to each other and, as a result, the fidelity susceptibility is not symmetric. The peak value of the reduced fidelity susceptibility defines a critical mass \( M_{c,\chi_F} \approx 1.8/L \), which differs from the critical mass obtained by other means.

Our theory applies to topological phase transitions in which the winding number changes by one. This is because we considered the gap closing of a single Dirac fermion. More generally, a theory of \( n \) Dirac fermions applies to certain transitions where the topological winding changes by \( n \). In the absence of scattering between different Dirac valleys, the fidelity susceptibility is the sum of the expressions reported in this paper.

Since this study was devoted to the universal scaling function of the fidelity susceptibility for 1D Dirac fermions one may wonder about a similar function in higher dimensions. However, such a universal function should not exist, inasmuch as the fidelity susceptibility is expected to depend on the ultraviolet cut-off for \( \nu d \geq 2 \). Moreover, the generalization of our results to the case of arbitrary \( \delta ML \) in Eq. (2) would reveal further experimentally accessible insights on the orthogonality catastrophe and the role of edge states. Specifically, the overlap function of groundstates on different sides of the transition vanishes for PBC, but not in the case of other boundary conditions.

Finally, more theoretical work is needed to relate our results for the fidelity susceptibility in finite Ising systems to quantities studied in experiments or by other theoretical methods, such as (boundary) conformal field theory. In particular, the connection between the fidelity and boundary entropy of certain conformally invariant, finite \((1+1)\) dimensional systems was shown in Ref. \([12]\). It would be interesting to investigate the Ising critical point in the same spirit.

Supplemental Material:
Universal fidelity near quantum and topological phase transitions in finite 1D systems

JORDAN-WIGNER TRANSFORMATION

In this appendix, we review the duality between 1D XY-magnets and the 1D fermionic models for TPM and clarify the notation used in table I of the main text.

We consider an XY magnet in a transverse field defined by

\[
H_{XY} = -\sum_{j=1}^{N-1} [J_x^{(j)} \sigma_j^x \sigma_{j+1}^x + J_y^{(j)} \sigma_j^y \sigma_{j+1}^y] - \hbar \sum_{j=1}^{N} \frac{\sigma_j^z}{2}.
\]

(S1)

Here, \(\sigma_j^{x,y,z}\) are spin operators (Pauli matrices) at site \(j\) and \(\hbar\) is the transverse field. For concreteness, we consider the following model of staggered, anisotropic interaction.

\[
J_x^{(j)} = J_x [1 + (-1)^j \delta],
\]

(S2a)

\[
J_y^{(j)} = J_y [1 + (-1)^j \delta].
\]

(S2b)

Using the standard Jordan-Wigner transformation, we rewrite the spin operators in terms of fermionic creation and annihilation operators \(c_j^\dagger, c_j\)

\[
\frac{\sigma_j^x \pm i \sigma_j^y}{2} = \begin{cases} 
  c_j^\dagger e^{-i \pi \sum_{k<j} c_k^\dagger c_k}, \\
  c_j e^{i \pi \sum_{k<j} c_k^\dagger c_k}, 
\end{cases} \quad (S3a)
\]

\[
\sigma_j^z = 2 c_j^\dagger c_j - 1. \quad (S3b)
\]

Under this transformation, the Hamiltonian becomes

\[
H_{XY} = -\sum_{j=1}^{N-1} [J_x^{(j)} + J_y^{(j)}] (c_j^\dagger c_{j+1}^\dagger + c_j^\dagger c_{j+1}) + \sum_{j=1}^{N-1} [J_x - J_y] (c_j^\dagger c_j + c_j^\dagger c_{j+1}) - \hbar \sum_{j=1}^{N} \left( c_j^\dagger c_j - \frac{1}{2} \right). \quad (S4)
\]

The identification of the physical meaning of the various terms (hopping \(t = J_x + J_y\), p-wave pairing \(\Delta = J_x - J_y\), staggered hopping \(\delta\) and chemical potential \(\mu = \hbar\)) immediately follows.

FIDELITY AND FIDELITY SUSCEPTIBILITY

In this appendix, we present details on the derivation of the main result of our paper: The fidelity susceptibility for the Ising transition in 1D described by the Hamiltonian Eq. (1). (Equation numbers without “S” refer to the main text.) This appendix contains a section on the symmetry properties of the fidelity susceptibility and the analytical derivation of the results.

Symmetry property of the Fidelity susceptibility

We here show that the fidelity susceptibility evaluated by means of empty states equals the fidelity susceptibility evaluated by all filled states. As a corollary, it follows for the Dirac Hamiltonian, Eq. (1), that the fidelity susceptibility evaluated using all states with energy \(E < 0\) equals the fidelity susceptibility evaluated using all states with energy \(E \leq 0\).

We use the notation

\[
A_{p,p'} = \langle \psi_{(p,M-\delta M/2,-)} | \psi_{(p',M+\delta M/2,-)} \rangle \quad (S5)
\]

for the overlap matrix of states with eigenenergy less than or equal to the Fermi energy \(E_F\). In our case \(|\psi_{(p,M\pm \delta M/2,-)}\rangle\) are negative-energy eigenstates of Eq. (1) with \(m = -(M \pm \delta M/2)\).
We rewrite the definition of the fidelity, Eq. (2), as follows
\[
\mathcal{F} = \sqrt{\det[A A^\dagger]}.
\] (S6)

The fidelity susceptibility is thus (the limit \(\delta M \to 0\) is to be understood in all of the following expressions)
\[
\chi_F = -\frac{1}{\delta M^2 L} \text{tr}[AA^\dagger - 1] + \frac{1}{2\delta M^2 L} \text{tr}[(AA^\dagger - 1)^2] - \frac{1}{2\delta M^2 L} (\text{tr}[AA^\dagger - 1])^2
\] (S7a)

\[
= -\frac{1}{\delta M^2 L} \text{tr}[[A^E > E_F A^E > E_F, \dagger - 1] + \frac{1}{2\delta M^2 L} \text{tr}[[A^E > E_F A^E > E_F, \dagger - 1] - \frac{1}{2\delta M^2 L} (\text{tr}[A^E > E_F A^E > E_F, \dagger - 1])^2.
\] (S7b)

The second line follows from the orthonormality and completeness of \([|\psi[p, M \pm \delta M/2, \text{sgn}(E - E_F)]\rangle\}. Here, we have introduced the overlap matrix \(A^E_F\) of empty states, defined analogously to Eq. (S5).

Turning back to our problem of 1D Dirac fermions, we use the chiral symmetry of the Hamiltonian \(\{H, \tau_y\} = 0\), to relate all nonnegative energy states to all nonpositive energy states. It follows that the fidelity susceptibility for \(E_F = 0^\pm\) equals the fidelity susceptibility for \(E_F = 0^\pm\). This proves the following assertion from the main text: The single edge state, which is present for asymmetric, open boundary contributions, does not contribute to the fidelity susceptibility.

Notation

Using the Taylor expansion
\[
A \approx 1 + A^{(1)} \delta M + A^{(2)} \delta M^2/2,
\] (S8)

Eq. (S7a) and the fact \(\text{tr}[A^{(1)} + A^{(1), \dagger}] = 0\), we rewrite the fidelity susceptibility as follows
\[
\chi_F = \chi_{F, 1} + \chi_{F, 2},
\] (S9a)

where
\[
\chi_{F, 1} = -\frac{1}{2L} \text{tr}[A^{(2)} + A^{(2), \dagger}], \quad \chi_{F, 2} = \frac{1}{2L} \text{tr}[(A^{(1)})^2 + (A^{(1), \dagger})^2].
\] (S9b)

Closed boundary conditions

We first calculate the fidelity susceptibility in the case of periodic and antiperiodic boundary conditions.

Eigenstates. We assume \(m(x) = -M\) in Eq. (1) and periodic boundary conditions (PBC) \(\psi(x) = \psi(x + L)\) or antiperiodic boundary conditions (ABC) \(\psi(x) = -\psi(x + L)\). After Fourier transform (PBC: \(p = 2\pi n / L, n \in \mathbb{Z}\), ABC: \(p = \pi (2n - 1) / L, n \in \mathbb{Z}\)) we find the following eigenvectors associated to energy \(E = \pm \sqrt{p^2 + M^2}\):
\[
\psi_{(M, p, \text{sgn}(E))}(x) = \frac{1}{\sqrt{2}} \begin{pmatrix} -\text{sgn}(E) \sqrt{1 - M/E} \\ -\sqrt{1 + M/E} \end{pmatrix}.
\] (S10)

Fidelity and fidelity susceptibility. Since the discrete wavevectors \(k\) are good quantum numbers independently of the mass \(M\), the fidelity is the product of the overlap of all negative energy states.

\[
\mathcal{F} = \prod_k \langle \psi(M - \delta M/2, k, -) | \psi(M + \delta M/2, k, -) \rangle
\]
\[
= \exp \left\{ \sum_k \ln \langle \psi(M - \delta M/2, k, -) | \psi(M + \delta M/2, k, -) \rangle \right\}
\]
\[
\approx e^{-\frac{1}{2} \sum_k \frac{\delta M^2 k^2}{4(M^2 + k^2)^2}}
\]
\[
\approx 1 - \frac{\delta M^2 L}{2} \sum_k \frac{k^2}{4(M^2 + k^2)^2} \equiv \chi_F.
\] (S11)
We therefore find for PBC
\[ \chi_F = \sum_{n=-\infty}^{\infty} \frac{(2\pi n)^2}{4(M^2 + (2\pi n)^2)^2} = \frac{\sinh(M) - \bar{M}}{16M[\cosh(M) - 1]} \] (S12)
while for ABC we obtain
\[ \chi_F = \sum_{n=-\infty}^{\infty} \frac{(\pi(2n - 1))^2}{4(M^2 + (\pi(2n - 1))^2)^2} = \frac{\sinh(M) + \bar{M}}{16M[\cosh(M) + 1]} . \] (S13)

We here introduced \( \bar{M} = ML \). This concludes the derivation of Eq. [4] of the main text.

Open boundary conditions: asymmetric mass profile

We remark that the Hamiltonian Eq. [1] together with the mass profile implied by Eq. [7] has the following behavior under inversion:

\[ \mathcal{I}_y H \mathcal{I}_y = H |_{\bar{M} \rightarrow -\bar{M}} . \] (S14)

Here \( \mathcal{I} \) inverts \( x \rightarrow -x \) and we will classify the states by their parity at \( M = 0 \).

**Eigenstates.** We refer to the following solutions as even states (Eigenstates). We remark that the Hamiltonian Eq. (1) together with the mass profile implied by Eq. (7) has the following behavior

\[ \langle \psi_{(M,p,\text{sgn}(E))}^\pm(x) = \frac{(-1)^n}{\sqrt{2LE^2}} \left[ \begin{pmatrix} ip \sin(px) \\ (E + M) \cos(px) \end{pmatrix} + \begin{pmatrix} -i(E - M) \cos(px) \\ p \sin(px) \end{pmatrix} \right] \right] , \] (S15)

while odd states \((p = 2\pi n)/L\) are

\[ \psi_{(M,p,\text{sgn}(E))}^\pm(x) = \frac{(-1)^n}{\sqrt{2LE^2}} \left[ \begin{pmatrix} p \cos(px) \\ i(E + M) \sin(px) \end{pmatrix} + \begin{pmatrix} (E - M) \sin(px) \\ -ip \cos(px) \end{pmatrix} \right] . \] (S16)

Again, \( E = \pm \sqrt{p^2 + M^2} \) and \( n \in \mathbb{N} \). The following property can be readily checked:

\[ \mathcal{I}_y \psi_{(M,p)}^\pm(x) \equiv \tau_y \psi_{(M,p)}^\pm(-x) = \pm \psi_{(-M,p)}^\pm(x) . \] (S17)

For the boundary state, it is useful to keep in mind the full space dependence of the mass \( m(x) \), even for \(|x| > L/2\), see Fig. 2. In this way normalizability imposes the following wave function to be the only zero mode

\[ \psi_{(M,0)}(x) = \sqrt{\frac{M}{\sinh(ML)}} \frac{e^{-Mx}}{\sqrt{2}} \begin{pmatrix} 1 \\ -i \end{pmatrix} . \] (S18)

**Wave function overlap.** For the evaluation of the fidelity susceptibility we need the wave function overlap, of which we expand diagonal elements up to second order in \( \delta M \) and off diagonal elements to first order.

\[ \langle \psi_{(M - \delta M/2, p, -)}^\pm | \psi_{(M + \delta M/2, p', -)}^\pm \rangle \simeq 1 - \frac{\delta M^2 p^2}{4(M^2 + p^2)^2} \delta_{pp'} , \] (S19a)

\[ \langle \psi_{(M - \delta M/2, p, -)}^\pm | \psi_{(M + \delta M/2, p', -)}^\pm \rangle \simeq 1 - \frac{\delta M^2 p^2}{4(M^2 + p^2)^2} \delta_{pp'} , \] (S19b)

\[ \langle \psi_{(M - \delta M/2, 0)} | \psi_{(M + \delta M/2, 0)} \rangle \simeq 1 - \frac{\delta M^2 L^2}{8} \left( \frac{(ML)^2 + 1}{(ML)^2} - \frac{1}{\tanh^2(ML)} \right) , \] (S19c)

\[ \langle \psi_{(M - \delta M/2, p, -)}^\pm | \psi_{(M + \delta M/2, p', -)}^\pm \rangle \simeq \frac{-2i\delta M}{\sqrt{p^2 + M^2} \sqrt{(p')^2 + M^2} L (p')^2 - p^2} , \] (S19d)

\[ \langle \psi_{(M - \delta M/2, 0)} | \psi_{(M + \delta M/2, 0)}^\pm \rangle \simeq (-1)^n \frac{2i \delta M \cosh(ML/2)}{(M^2 + p^2)^{3/2}} \sqrt{\frac{M}{\sinh(ML)}}, \] (S19f)

\[ \langle \psi_{(M - \delta M/2, 0)} | \psi_{(M + \delta M/2, -)}^\pm \rangle \simeq (-1)^n \frac{2i \delta M \sinh(ML/2)}{(M^2 + p^2)^{3/2}} \sqrt{\frac{M}{\sinh(ML)}} . \] (S19f)
Evaluation of fidelity susceptibility. Using the above expressions for the wave function overlap we obtain for the case \( E_F = 0^- \)

\[
\chi_{F,1} = \sum_{n \in \mathbb{N}} \frac{\left(n\pi\right)^2}{2\left(n\pi\right)^2 + M^2} = \frac{\coth(M) - M \text{csch}^2(M)}{8M}, \quad (S20a)
\]

\[
\chi_{F,2} = \sum_{n,m \in \mathbb{N}} \frac{(2n\pi)^2((2m-1)\pi)^2}{\left[(2n\pi)^2 - ((2m-1)\pi)^2\right]^2 \left[(2n\pi)^2 + M^2\right]^2} = \frac{\left(2n\pi\right)^2}{16M^2} \left[1 + M \left[\text{csch}(M) - \coth \left(\frac{M}{2}\right)\right]\right]. \quad (S20b)
\]

The sum of these expressions leads to Eq. [8] of the main text. In the case \( E_F = 0^+ \) we include the following additional contribution to \( \chi_{F,2} \):

\[
\frac{\Delta \chi_{F,2}}{L} = -8 \sum_{n \in \mathbb{N}} \frac{M}{\sinh(M)} \left[ \cosh \left(\frac{M}{2}\right) \frac{\left((2n-1)\pi\right)^2}{\left[(2n-1)\pi)^2 + M^2\right]^2} + \sinh^2 \left(\frac{M}{2}\right) \frac{(2n\pi)^2}{\left[(2n\pi)^2 + M^2\right]^3} \right]
\]

\[
= \frac{-（2M^2 + \cosh(2M) - 1) \text{csch}^2(M)}{8M^2}. \quad (S21)
\]

This contribution exactly compensates the effect of the wave function overlap of zeromodes, Eq. [S19c],

\[
\frac{\Delta \chi_{F,1}}{L} = \frac{1}{4} \left(\frac{M^2 + 1}{M^2} - \frac{1}{\tanh^2(M)}\right) = -\frac{\Delta \chi_{F,2}}{L}, \quad (S22)
\]

as required by the general statement, according to which \( \chi_F|_{E_F=0^-} = \chi_F|_{E_F=0^+} \).

Open boundary conditions: symmetric mass profile

We first investigate the symmetry properties of the Hamiltonian, Eq. [1], together with the mass profile implied by Eq. [7] under inversion. We find that the Hamiltonian commutes with the following inversion operator:

\[
[H, \mathcal{I} \tau_z] = 0. \quad (S23)
\]

As before, \( \mathcal{I} \) inverts \( x \rightarrow -x \). We will classify the states by their parity.

**Eigenstates.** The wave functions of even (+) and odd (-) states are

\[
\psi_{(M,p,\text{sgn}(E))}^+(x) = \mathcal{N}_{(M,p)} \begin{pmatrix} \cos(px) \\ i \sin(px) \end{pmatrix} \quad \text{and} \quad \psi_{(M,p,\text{sgn}(E))}^-(x) = \mathcal{N}_{(M,p)} \begin{pmatrix} \sin(px) \\ i \cos(px) \end{pmatrix} \quad (S24a)
\]

with normalization coefficient

\[
\mathcal{N}^{-1}_{(M,p)} = \sqrt{\int_{-L/2}^{L/2} \left[ \frac{\sin^2(px)}{\cos^2(pL/2)} + \frac{\cos^2(px)}{\sin^2(pL/2)} \right]} = \sqrt{\frac{2L[M^2 + p^2 - M/L]}{p^2}}. \quad (S24b)
\]

Note that \( \psi^- \) is the chiral partner of \( \psi^+ \), i.e. \( \psi^- = \tau_y \psi^+ \), and thus has opposite energy. Direct application of the Hamiltonian, Eq. [1], enforces the energy eigenvalues together with the quantization condition

\[
E = \pm(M + p\tan(pL/2)) \quad \text{and} \quad \frac{p}{M} = \tan(pL). \quad (S25)
\]

The quantization conditions of the different parity eigenstates separately are for even states

\[
\tan(pL/2) = \frac{p}{M + E}, \quad (S26a)
\]

and for odd states

\[
\tan(pL/2) = \frac{p}{M - E}. \quad (S26b)
\]
Each of the even and odd states quantization conditions imply one imaginary solution $p = i\varpi$, with $\varpi > 0$, for $ML > 1$, see Fig. S1. Physical solutions for real wave vectors have $p > 0$, in this case the dispersion relation is $E = \pm \sqrt{p^2 + M^2}$.

**Wave function overlap.** In view of the inversion symmetry of the problem, the overlap matrix is block-diagonal

$$
A_{k,k'} = \begin{pmatrix}
A^+_k & 0 \\
0 & A^-_{k,k'}
\end{pmatrix}
$$

with overlaps of negative energy eigenstates

$$
A^\pm_k = \langle \psi^\pm(ML-\delta M/2, p, \varpi) | \psi^\mp(ML+\delta M/2, p', \varpi) \rangle.
$$

Here, the momenta $p \simeq k + \mathcal{O}(\delta M)$ ($p' \simeq k' + \mathcal{O}(\delta M)$) obey the quantization condition for a system characterized by mass $M - \delta M/2$ ($M + \delta M/2$).

The overlap matrix takes the following value for both even and odd states as well as for the case when $k, k' = i\varpi \in i\mathbb{R}$.

$$
A^\pm_{k,k'} = A^-_{k,k'} = 4N(M-\delta M/2, p')N(M+\delta M/2, p') \frac{\delta ML}{\bar{p}^2 - \bar{p}'^2}.
$$

We need this expression up to $\mathcal{O}(\delta M^2)$. Keep in mind, that $\bar{p} = \bar{p}(\bar{M} - \bar{\delta M}/2)$ and $\bar{p}' = \bar{p}'(\bar{M} + \bar{\delta M}/2)$. (Barred quantities are $\bar{\delta M} = \delta ML$ and so on.)

**Partial cancellation of diagonal and off-diagonal susceptibilities.** In the calculation of the susceptibility in the case “SSH-even” we encounter a partial cancellation of contributions $\chi_{F,1}$ and $\chi_{F,2}$, as defined in Eqs. (S9). We here prove this partial cancellation on general grounds. In the subsequent section, we repeat the proof by explicit calculation, see Eq. (S43).

Returning to the notation of Eqs. (S5), we Taylor expand the states and use their normalization to find that

$$
A^{(1)}_{p,p'} = \langle \psi(p, M, -) | \frac{d}{dM} \psi(p', M, -) \rangle, \\
A^{(2)}_{p,p'} = -\langle \frac{d}{dM} \psi(p, M, -) | \frac{d}{dM} \psi(p', M, -) \rangle.
$$

In the following, we will use that the matrix $A$ is real in the present case. The proof can be readily extended to

---

**FIG. S1:** Left: Spectrum of wave vectors for the even states. Dark blue lines correspond to positive energy, light blue lines to negative energy. For the odd parity states, all states have opposite energy. Note the dotted line, which represents the imaginary wave vector $p = i\varpi$ of the bound state. It approaches the gray asymptote $\varpi = M$ from below. Right: The imaginary solution (blue dotted), together with the asymptotes $\varpi L \simeq \sqrt{3(ML - 1)}$ (dotdashed) valid for $ML \to 1$, $\varpi \simeq M(1 - 2e^{-2ML})$ (dashed) and $\varpi = M$ (solid), both valid for large $ML$. 

Physical solutions for real wave vectors have $p > 0$, in this case the dispersion relation is $E = \pm \sqrt{p^2 + M^2}$. The overlap matrix takes the following value for both even and odd states as well as for the case when $k, k' = i\varpi \in i\mathbb{R}$. 

$$
A^\pm_{k,k'} = A^-_{k,k'} = 4N(M-\delta M/2, p')N(M+\delta M/2, p') \frac{\delta ML}{\bar{p}^2 - \bar{p}'^2}.
$$

We need this expression up to $\mathcal{O}(\delta M^2)$. Keep in mind, that $\bar{p} = \bar{p}(\bar{M} - \bar{\delta M}/2)$ and $\bar{p}' = \bar{p}'(\bar{M} + \bar{\delta M}/2)$. (Barred quantities are $\bar{\delta M} = \delta ML$ and so on.)

**Partial cancellation of diagonal and off-diagonal susceptibilities.** In the calculation of the susceptibility in the case “SSH-even” we encounter a partial cancellation of contributions $\chi_{F,1}$ and $\chi_{F,2}$, as defined in Eqs. (S9). We here prove this partial cancellation on general grounds. In the subsequent section, we repeat the proof by explicit calculation, see Eq. (S43).

Returning to the notation of Eqs. (S5), we Taylor expand the states and use their normalization to find that

$$
A^{(1)}_{p,p'} = \langle \psi(p, M, -) | \frac{d}{dM} \psi(p', M, -) \rangle, \\
A^{(2)}_{p,p'} = -\langle \frac{d}{dM} \psi(p, M, -) | \frac{d}{dM} \psi(p', M, -) \rangle.
$$

In the following, we will use that the matrix $A$ is real in the present case. The proof can be readily extended to a
partially cancel the contributions from the off-diagonal part. We further use that odd states are the chiral partners of even states.

\[
\frac{\chi_{F,2}}{L} = \frac{1}{L} \sum_{p,k} A^{(1)}_{p,k} A^{(1)}_{p,k}
\]

\[
= -\frac{1}{L} \sum_{p,k} \left( \frac{d\psi_{(p,M,-)}^+}{dM} |\psi_{(k,M,-)}^+\rangle \langle \psi_{(k,M,-)}^+| - \frac{d\psi_{(p,M,-)}^-}{dM} |\psi_{(k,M,-)}^-\rangle \langle \psi_{(k,M,-)}^-| \right)
\]

\[
= -\frac{1}{L} \sum_{p,k} \left( \frac{d\psi_{(p,M,-)}^+}{dM} |\psi_{(k,M,-)}^+\rangle \langle \psi_{(k,M,-)}^+| + \frac{d\psi_{(p,M,+)}^-}{dM} |\psi_{(k,M,+)}^-\rangle \langle \psi_{(k,M,+)}^-| \right)
\]

\[
= \frac{1}{L} \left[ 2 \sum_{p,k} \left( \frac{d\psi_{(p,M,-)}^+}{dM} |\psi_{(k,M,+)}^+\rangle \langle \psi_{(k,M,+)}^+| - \frac{d\psi_{(p,M,+)}^-}{dM} |\psi_{(k,M,-)}^-\rangle \langle \psi_{(k,M,-)}^-| \right) \right]
\]

\[
= \frac{2}{L} \sum_{p,k} \left( \frac{d\psi_{(p,M,-)}^+}{dM} |\psi_{(k,M,+)}^+\rangle \langle \psi_{(k,M,+)}^+| + \frac{d\psi_{(p,M,+)}^-}{dM} |\psi_{(k,M,-)}^-\rangle \langle \psi_{(k,M,-)}^-| \right)\right]
\]

\[
= \chi_{F,1} \frac{L}{2}.
\]

In the very last line, we used the resolution of identity in the space of symmetric wave functions. We thus see, that contributions from diagonal parts of the matrix \(A\) partially cancel the contributions from the off-diagonal part. We now proceed with the explicit calculation.

**Diagonal contribution to fidelity susceptibility.** We expand the diagonal part of Eq. (S20) to second order in \(\delta M\). It is important to keep in mind that all wave vectors are a function of the mass \(\bar{\bar{p}} = \bar{p}(\bar{\bar{M}})\). We obtain

\[
A_{k,k} = 1 - \frac{(\delta ML)^2}{24} \sum_{n=1}^{4} \frac{2A_{n}(\bar{\bar{M}})}{D_k}
\]

where \(D_k = \bar{k}^2 + \bar{\bar{M}}^2 - \bar{\bar{M}}\) and

\[
A_1(\bar{\bar{M}}) = 2,
\]

\[
A_2(\bar{\bar{M}}) = -(9 - 20\bar{\bar{M}} + 4\bar{\bar{M}}^2)/2,
\]

\[
A_3(\bar{\bar{M}}) = -4\bar{\bar{M}}(3 - 5\bar{\bar{M}} + 2\bar{\bar{M}}^2),
\]

\[
A_4(\bar{\bar{M}}) = -6(\bar{\bar{M}}^2 - \bar{\bar{M}})^2.
\]

For the analytic solution we solve the following sums

\[
s_n(\bar{\bar{M}}) = \sum_{\bar{\bar{k}} \in E \setminus \{0\}} \frac{1}{(\bar{k}^2 + \bar{\bar{M}}^2 - \bar{\bar{M}})^n},\quad E = \{\bar{\bar{k}} \in \mathbb{C} | f(\bar{\bar{k}}) \equiv \tan(\bar{\bar{k}}) - \bar{\bar{k}}/\bar{\bar{M}} = 0\}.
\]

by contour integration leading to the following final expression

\[
\frac{\chi_{F,1}}{L} = \frac{10\bar{\bar{M}} - 9}{48\bar{\bar{M}}^2} - \frac{\bar{\bar{M}}^2 - \bar{\bar{M}}}{8\bar{\bar{M}}^2} \left( \sqrt{(\bar{\bar{M}} - 1)\bar{\bar{M}} - \bar{\bar{M}}\tanh(\sqrt{(\bar{\bar{M}} - 1)\bar{\bar{M}}})} \right)^2
\]

\[
+ \frac{-12\bar{\bar{M}}^2 + 20\bar{\bar{M}} - 21}{48\bar{\bar{M}}\sqrt{(\bar{\bar{M}} - 1)\bar{\bar{M}} - \bar{\bar{M}}\tanh(\sqrt{(\bar{\bar{M}} - 1)\bar{\bar{M}}})}} - \frac{4\bar{\bar{M}}^3 - 8\bar{\bar{M}}^2 + 4\bar{\bar{M}} + 3}{24(\bar{\bar{M}} - 1)^2\bar{\bar{M}}^2}.\]

**Off-diagonal contribution to fidelity susceptibility.** The off-diagonal matrix elements contribute to the fidelity susceptibility as follows

\[
\chi_{F,2} = -4L\sigma(\bar{\bar{M}}) = -4L[\sigma_1(\bar{\bar{M}}) + \sigma_2(\bar{\bar{M}})]
\]

where

\[
\sigma_1(\bar{\bar{M}}) = \frac{1}{4} \sum_{\bar{\bar{k}} \in E \setminus \{0\}} \sum_{l \in E \setminus \{\pm \bar{\bar{k}}\}} \frac{\bar{k}^2\bar{\bar{l}}^2}{D_k D_l (\bar{\bar{l}}^2 - \bar{\bar{k}}^2)^2}
\]

\[
\sigma_2(\bar{\bar{M}}) = -\frac{1}{2} \sum_{\bar{\bar{k}} \in E^+} \frac{\bar{k}^2\bar{\bar{l}}^2}{D_k D_l (\bar{\bar{l}}^2 - \bar{\bar{k}}^2)^2}
\]
Here we introduced
\[ E^+ := \{ \bar{k} \in \mathbb{C} | f_{\text{even}}(\bar{k}) = 0 \}, \]
\[ E^- := \{ \bar{k} \in \mathbb{C} | f_{\text{odd}}(\bar{k}) = 0 \}, \]
with
\[ f_{\text{even/odd}}(\bar{k}) = \frac{\bar{k}}{M \mp \sqrt{k^2 + M^2}}. \]

The imaginary solution \( \bar{k} = i\pi \) solves \( f_{\text{odd}}(i\pi L) = 0 \) for \( \bar{M} > 1 \) and is thus an element of \( E^- \).

It turns out that \( \sigma_1 \) can be solved in a closed form by taking a contour integral:
\[ \sigma_1(\bar{M}) = \frac{(\bar{M} - 4)(2\bar{M} - 5) - 15}{192(\bar{M} - 1)^2 M^2} - \frac{\bar{M} - 1}{32\bar{M} \left( \bar{M} \tanh \left( \sqrt{M^2 - \bar{M}} \right) - \sqrt{M^2 - \bar{M}} \right)^2} + \frac{12\bar{M}^2 - 20\bar{M} + 21}{192\bar{M} \sqrt{(\bar{M} - 1)\bar{M} \left( \bar{M} \tanh \left( \sqrt{M^2 - \bar{M}} \right) - \sqrt{M^2 - \bar{M}} \right)}}. \]

We thus find that
\[ \chi_{F,1} - 4L\sigma_1 = 0, \]
in accordance with Eq. (S31). The only contribution to the fidelity susceptibility stems from \( \sigma_2(\bar{M}) \):
\[ \frac{\chi_{F}}{L} = 2 \sum_{\bar{k} \in E^+} \sum_{\bar{l} \in E^-} \frac{\bar{k}^2 l^2}{D_{\bar{k}}D_{\bar{l}} (\bar{l}^2 - \bar{k}^2)^2}. \]

We thus derived the result presented in Eq. (9) of the main text.

**Evaluation of fidelity susceptibility.** We proceed with the evaluation of the sum (S43) for the fidelity susceptibility. We use the following notation
\[ \sigma_2(\bar{M}) = -\frac{1}{2} \sum_{\bar{k} \in E^+} \sigma_{2,\text{odd}}(\bar{k}, \bar{M}) - \frac{1}{2} \sum_{\bar{k} \in E^-} \sigma_{2,\text{even}}(\bar{k}, \bar{M}) \]

For the contour integration, see Fig. S2 we exploit the properties of the complex function
\[ \tilde{g}_{\text{even}}(\bar{l}) = \frac{\mp D_{\bar{l}}}{\sqrt{l^2 + M^2} f_{\text{even}}(\bar{l})} = \frac{D_{\bar{l}}}{2} \left( \pm \frac{\tilde{g}_1(\bar{l})}{\sqrt{l^2 + M^2}} + \tilde{g}_2(\bar{l}) \right) \]
\[ \approx \frac{1}{l - \bar{k}_s} \begin{cases} \text{for } \bar{l} \to \bar{k}_s, \bar{k}_s \in E^+ \text{ (upper sign)}, \\ \text{for } \bar{l} \to \bar{k}_s, \bar{k}_s \in E^- \text{ (lower sign)}. \end{cases} \]

Here we introduced
\[ \tilde{f}_{\text{odd}}(\bar{l}) = (\bar{M} \mp \sqrt{l^2 + M^2}) \tan(\bar{l}/2) - \bar{l}, \]
\[ \tilde{g}_1(\bar{l}) = \frac{1}{l} + \frac{1}{l \cos(l) - M \sin(l)}, \]
\[ \tilde{g}_2(\bar{l}) = -\frac{\sin(l)}{l[l \cos(l) - M \sin(l)]}. \]
FIG. S2: Integration contour for the evaluation of the sum $\sigma_2^{\text{even}}(\bar{k}, M)$ (left) and of the sum $\sum_{\bar{k} \in E^-} \sigma_2^{\text{even}}(\bar{k}, M)$ (right).

This leads to

$$
\sigma_2^{\text{odd}}(\bar{k}, M) = \frac{1}{2} \sum_{\bar{k} \in E^-} \frac{\bar{k}^2\bar{l}^2}{D_k D_l (k^2 - l^2)^2}
$$

$$
= \frac{\bar{k}^2(k^2 + M^2 + 3M)}{16D_k (k^2 + M^2)^2} + I_2(\bar{k}, M) 
= \frac{\bar{k}^2(k^2 + M^2 + 3M)}{16D_k (k^2 + M^2)^2} - I_2(\bar{k}, M).
$$

(S46)

$$
\sigma_2^{\text{even}}(\bar{k}, M) = \frac{1}{2} \sum_{\bar{k} \in E^+} \frac{\bar{k}^2\bar{l}^2}{D_k D_l (k^2 - l^2)^2}
$$

$$
= \frac{\bar{k}^2(k^2 + M^2 + 3M)}{16D_k (k^2 + M^2)^2} - I_2(\bar{k}, M).
$$

(S47)

Here, we introduced

$$
I_2(\bar{k}, M) = \frac{\bar{k}^2}{2D_k \bar{\xi}} \frac{1}{\pi} \int_{|\bar{M}|}^{\infty} dx \frac{x^2}{\sqrt{x^2 - M^2}} \frac{1}{x} \frac{1}{\tanh(x) \cosh \left( \frac{1}{k^2 + x^2} \right)}
$$

(S48)

The second contour integration, cf. Fig. S2 (right), which is introduced to remove the $\bar{k}$ summation leads to the final expression for $\chi_F$

$$
\chi_F \frac{L}{L} = \frac{-1}{16} \left\{ \frac{-1}{M} + \frac{3 + 4\bar{M}}{M^2(1 - \tanh(M))} - \frac{3}{(1 - \tanh(M))^2 M^2} \right\}
$$

$$
- \frac{2}{\pi^2} \lim_{n \to 0} \int_1^{\infty} \int_{1}^{\infty} \frac{du^2}{\sqrt{u^2 - 1}} \frac{dv^2}{\sqrt{v^2 - 1}} \frac{(u^2 - v^2)^2 - \eta^2}{[u^2 - v^2 + \eta^2]^2}
$$

$$
\times \frac{1}{\cosh(Mu)[u - \tanh(Mu)] \cosh(Mv)[v - \tanh(Mv)]}
$$

(S49)

The second contribution, a principle value integral which stems from $I_2$, vanishes in the limit $ML \ll -1$. Due to the cancelling of exponential divergencies in the square bracket and the integral for $ML \to \infty$, it is numerically more stable to evaluate the fidelity by means of the sum, Eq. (S43). This is how the plots, Figs. 1 and 3 were generated.

Asymptotic behavior

For the calculation of the asymptotic behavior of the quantum fidelity, we use the following approximate real solutions to Eq. (S26)

$$
\bar{p} \left| \bar{\eta} \right| > 1 \geq \pi n + \arctan \left( \frac{\pi n}{M} \right)
$$

(S50)
For \( M > 0 \) (\( M < 0 \)) \( n \) is even for odd (even) states and odd for even (odd) states. We use that, for \(|\vec{M}| \gg 1\) and any \( n, m \in \mathbb{N}\),

\[
\arctan\left(\frac{2n\pi}{M}\right) + \arctan\left(\frac{(2m-1)\pi}{M}\right) \ll 2n\pi + (2m-1)\pi, \tag{S51a}
\]

\[
\left|\arctan\left(\frac{2n\pi}{M}\right) - \arctan\left(\frac{(2m-1)\pi}{M}\right)\right| \ll |2n\pi - (2m-1)\pi|, \tag{S51b}
\]

so that we can expand the dispersive wave contribution to the sum Eq. (S43) as follows

\[
\chi_{F|L| \text{waves}} \simeq 8 \sum_{n,m \in \mathbb{N}} \left[ \frac{\vec{k}^2 l^2}{D_k D_l (l^2 - k^2)} + \frac{2\vec{k}^2 \vec{l} (\vec{k}^2 \vec{M}^2 + 2\vec{l}^4 + \vec{l}^2 \vec{M}^2)}{(k^2 - \vec{l}^2)^3 (k^2 + \vec{M}^2) (\vec{l}^2 + \vec{M}^2)^2} \arctan\left(\frac{\vec{l}}{\vec{M}}\right) \right]_{\vec{k}=2n\pi, \vec{l}=(2m-1)\pi} \tag{S52}
\]

The first part of the sum is equivalent to Eq. (S20b). In the second term it is convenient to perform the \( \vec{k} \) summation first, and then evaluate the sum over \( \vec{l} \) as a Riemann integral. We keep only the leading and subleading contributions for \( \vec{M} \to \infty \) and obtain

\[
\chi_{F|L| \text{waves}} \simeq \frac{1}{16} \left( \frac{1}{|\vec{M}|} - \frac{4 + \text{sgn}(\vec{M})}{4\vec{M}^2} \right). \tag{S53}
\]

For \( \vec{M} \gg 1 \), there is an additional contribution from the edge state

\[
\chi_{F|L| \text{edge+waves}} \simeq 8\vec{M} \sum_{m \in \mathbb{N}} \left[ \frac{\vec{l}^2}{(l^2 + M^2)^3} \right]_{l=(2m-1)\pi} \simeq \frac{1}{4\vec{M}^2}. \tag{S54}
\]

This concludes the derivation of Eqs. (10) of the main text. Note that the behavior for \( ML \ll -1 \) can also be read off from Eq. (S49).
