Stability Analysis of Recurrent Neural Networks by IQC with Copositive Multipliers

Yoshio Ebihara, Hayato Waki, Victor Magron, Ngoc Hoang Anh Mai, Dimitri Peaucelle, Sophie Tarbouriech

Abstract — This paper is concerned with the stability analysis of the recurrent neural networks (RNNs) by means of the integral quadratic constraint (IQC) framework. The rectified linear unit (ReLU) is typically employed as the activation function of the RNN, and the ReLU has specific nonnegativity properties regarding its input and output signals. Therefore, it is effective if we can derive IQC-based stability conditions with multipliers taking care of such nonnegativity properties. However, such nonnegativity (linear) properties are hardly captured by the existing multipliers defined on the positive semidefinite cone. To get around this difficulty, we loosen the standard positive semidefinite cone to the copositive cone, and employ copositive multipliers to capture the nonnegativity properties. We show that, within the framework of the IQC, we can employ copositive multipliers (or their inner approximation) together with existing multipliers such as Zames-Falb multipliers and polytopic bounding multipliers, and this directly enables us to ensure that the introduction of the copositive multipliers leads to better (no more conservative) results. We finally illustrate the effectiveness of the IQC-based stability conditions with the copositive multipliers by numerical examples.

Keywords: recurrent neural networks, rectified linear units, stability, IQC, nonnegatives signals, copositive multipliers.

I. INTRODUCTION

A recurrent neural network (RNN) is a class of deep neural networks and able to imitate the behavior of dynamical systems due to its feedback mechanism. The effectiveness of the RNN is widely recognized in speech recognition, natural language processing, and image recognition [1], [2], [3]. Even though new architectures such as transformer [4] have been developed recently, it is expected that the RNN retains its position as one of the fundamental and important elements in deep neural networks.

Even though the feedback mechanism is the key of the RNN and distinguishes the RNN from other feedforward networks, the existence of the feedback mechanism may cause network instability. Therefore the stability analysis of the RNN has been an important issue in the machine learning community [1], [2], [3]. From control theoretic viewpoint, we can readily apply the small gain theorem [5] to the stability analysis of a given RNN by representing it as a feedback connection with a linear time-invariant (LTI) system and a static nonlinear activation function typically being a rectified linear unit (ReLU) for the RNN. It is nonetheless true that the standard small gain theorem leads to conservative results since it does not take into account the important property that the ReLU returns only nonnegative signals. This motivated us to analyze the $l_2$ induced norm of LTI systems for nonnegative input signals in [6], which is referred to as the $l_{2+}$ induced norm in this paper. We characterized an upper bound of the $l_{2+}$ induced norm by copositive programming [7], and then derived a numerically tractable semidefinite program (SDP) for (in general loosened) upper bound computation. We finally derived an $l_{2+}$-induced-norm-based (scaled) small gain theorem for the stability analysis of the RNN and illustrated its effectiveness by numerical examples.

We believe that the treatments in [6] brought some new insights for the stability analysis of feedback systems constructed from LTI systems and nonlinear elements (i.e., Lur’e systems). However, the $l_{2+}$-induced-norm-based (scaled) small gain condition might be shallow in view of the advanced integral quadratic constraint (IQC) theory [8]. We acknowledge the fact that, for the stability analysis of Lur’e systems, the effectiveness of the IQC-based approaches with Zames-Falb multipliers [9] are widely recognized, see, e.g., [10], [11]. Therefore it is strongly preferable if we can build the nonnegativity-based approach upon the powerful IQC-based framework. Such an extension seems hard, since, as the denomination IQC says, the existing multipliers capture the properties of nonlinear elements with quadratic constraints on their input-output signals, whereas the nonnegativity property of the RNN (i.e., ReLU) is essentially linear constraints on the input-output signals. To get around this difficulty, we loosen the standard positive semidefinite cone to the copositive cone and employ copositive multipliers to handle the linear (nonnegativity) constraints on the input-output signals of the RNN. As clarified later on, this can be done in such a sound way that the proposed IQC-based stability condition with the copositive multipliers encompasses the results in [6] as particular cases. Then, by applying an inner approximation to the copositive cone, we derive numerically tractable IQC-based SDPs for the stability analysis of the RNN. We show that, within the framework of IQC, we can employ copositive multipliers (or their inner approximation) together with existing multipliers such as the Zames-Falb multipliers and polytopic bounding multipliers, and this directly enables us to ensure that the introduction of the copositive multipliers leads to better (no more conservative) results. We finally illustrate the effectiveness of the IQC-
based stability conditions with the copositive multipliers by using the same numerical examples as in [6]. Related works include [12], [13], [14], [15], but again the novel contribution of the present paper is capturing the behavior of ReLUs by copositive multipliers within the framework of IQCs.

Notation: The set of $n \times m$ real matrices is denoted by $\mathbb{R}^{n \times m}$, and the set of $n \times m$ entrywise nonnegative matrices is denoted by $\mathbb{R}_{+}^{n \times m}$. For a matrix $A$, we also write $A \geq 0$ to denote that $A$ is entrywise nonnegative. We denote the set of $n \times n$ real symmetric matrices by $\mathbb{S}^{n}$. For $A \in \mathbb{S}^{n}$, we write $A \succ 0$ ($A \prec 0$) to denote that $A$ is positive (negative) definite. For $A \in \mathbb{R}_{+}^{n \times n}$, we define $\text{He}(A) := A + A^T$. For $A \in \mathbb{R}_{+}^{n \times n}$ and $B \in \mathbb{R}_{+}^{n \times m}$, $(*)^T AB$ is a shorthand notation of $B^T AB$. We denote by $\mathcal{D}_{++}^{n} \subset \mathbb{R}^{n \times n}$ the set of diagonal matrices with strictly positive diagonal entries. In addition, we denote by $\mathcal{D}[\alpha, \beta]$ the set of diagonal matrices whose diagonal entries are all within the closed interval $[\alpha, \beta]$. Moreover, $\mathcal{D}[\alpha, \beta] \subset \mathcal{D}[\alpha, \beta]$ is the set of $2^n$ matrices corresponding to the vertices of $\mathcal{D}[\alpha, \beta]$. A matrix $M \in \mathbb{R}^{n \times n}$ is said to be $Z$-matrix if $M_{ij} \leq 0$ for all $i \neq j$. Moreover, $M$ is said to be doubly hyperdominant if it is a $Z$-matrix and $M1_n \geq 0$, $1_n^T M \geq 0$, where $1_n \in \mathbb{R}^{n}$ is the all-ones-vector. In this paper we denote by $\mathcal{D}[\alpha, \beta] \subset \mathbb{R}^{n \times n}$ the set of doubly hyperdominant matrices.

For the discrete-time signal $w$ defined over the time interval $[0, \infty)$, we define

$$\|w\|_2 := \sqrt{\sum_{k=0}^{\infty} |w(k)|^2}$$

where for $v \in \mathbb{R}^{n}$ we define $|v|_2 := \sqrt{\sum_{j=1}^{n} v_j^2}$. We also define

$$l_2 := \{w : \|w\|_2 < \infty \},$$

$$l_{2+} := \{w : w \in l_2, w(k) \geq 0 \ (\forall k \geq 0) \}$$

and

$$l_{2e} := \{w : w_\tau \in l_2, \ \forall \tau \in [0, \infty) \}$$

where $w_\tau$ is the truncation of the signal $w$ up to the time instant $\tau$ and defined by

$$w_\tau(k) = \begin{cases} w(k) & (k \leq \tau), \\ 0 & (k > \tau). \end{cases}$$

For an operator $H : l_{2e} \ni w \to z \in l_{2e}$, we define its (standard) $l_2$ induced norm by

$$\|H\|_2 := \sup_{w \in l_2} \frac{\|z\|_2}{\|w\|_2}. \quad (1)$$

We also define

$$\|H\|_{2+} := \sup_{w \in l_{2+}, \|w\|_2 = 1} \|z\|_2. \quad (2)$$

This is a variant of the $l_2$ induced norm introduced in [6] and referred to as the $l_{2+}$ induced norm in this paper. We can readily see that $\|H\|_{2+} \leq \|H\|_2$.

II. COPositive Programming

Copositive programming (COP) is a convex optimization problem in which we minimize a linear objective function over the linear matrix inequality (LMI) constraints on the copositive cone [7]. In this section, we summarize its basics.

A. Convex Cones Related to COP

Let us review the definition and the property of convex cones related to COP.

**Definition 1:** [16] The definition of proper cones $\mathcal{PSD}_n$, $\mathcal{CPP}_n$, $\mathcal{CN}_n$, and $\mathcal{DN}_n$ in $\mathbb{S}^n$ are as follows.

1. $\mathcal{PSD}_n := \{P \in \mathbb{S}^n : \forall x \in \mathbb{R}^n, x^T Px \geq 0\} = \{P \in \mathbb{S}^n : \exists B \text{ s.t. } P = BB^T\}$ is called the positive semidefinite cone.

2. $\mathcal{CPP}_n := \{P \in \mathbb{S}^n : \forall x \in \mathbb{R}^n, x^T Px \geq 0\}$ is called the copositive cone.

3. $\mathcal{CN}_n := \{P \in \mathbb{S}^n : \exists B \geq 0 \text{ s.t. } P = BB^T\}$ is called the completely positive cone.

4. $\mathcal{NN}_n := \{P \in \mathbb{S}^n : P \succeq 0\}$ is called the nonnegative cone.

5. $\mathcal{PSD}_n + \mathcal{NN}_n := \{P + Q : P \in \mathcal{PSD}_n, Q \in \mathcal{NN}_n\}$ is the Minkowski sum of the positive semidefinite cone and the nonnegative cone.

6. $\mathcal{DN}_n := \mathcal{PSD}_n \cap \mathcal{NN}_n$ is called the doubly nonnegative cone.

From Definition 1 we clearly see that the following inclusion relationships hold:

$$\mathcal{CP}_n \subset \mathcal{DN}_n \subset \mathcal{PSD}_n \subset \mathcal{PSD}_n + \mathcal{NN}_n \subset \mathcal{CPP}_n.$$ \quad (3)

$$\mathcal{CP}_n \subset \mathcal{DN}_n \subset \mathcal{PSD}_n + \mathcal{NN}_n \subset \mathcal{CPP}_n.$$ \quad (4)

In particular, when $n \leq 4$, it is known that $\mathcal{CPP}_n = \mathcal{PSD}_n + \mathcal{NN}_n$ and $\mathcal{CP}_n = \mathcal{DN}_n$ hold [16]. On the other hand, as for the duality of these cones, $\mathcal{CPP}_n$ and $\mathcal{CP}_n$ are dual to each other, $\mathcal{PSD}_n + \mathcal{NN}_n$ and $\mathcal{DN}_n$ are dual to each other, and $\mathcal{PSD}_n$ and $\mathcal{NN}_n$ are self-dual. It is also well known that the interior of the cone $\mathcal{PSD}_n$ can be characterized by

$$\mathcal{PSD}_n^o = \{P \in \mathbb{S}^n : \forall x \in \mathbb{R}^n \setminus \{0\}, x^T Px > 0\} = \{P \in \mathbb{S}^n : \exists B \text{ s.t. } P = BB^T, \ \text{rank}(B) = n\}.$$ \quad (5)

B. Basic Properties of COP

COP is a convex optimization problem on the copositive cone and its dual is a convex optimization problem on the completely positive cone. As mentioned in [7], the problem to determine whether a given symmetric matrix is copositive or not is a co-NP complete problem, and the problem to determine whether a given symmetric matrix is completely positive or not is an NP-hard problem. Therefore, it is hard to solve COP numerically in general. However, since the problem to determine whether a given matrix is in $\mathcal{PSD} + \mathcal{NN}$ or in $\mathcal{DN}$ can readily be reduced to SDPs, we can numerically solve the convex optimization problems on the cones $\mathcal{PSD} + \mathcal{NN}$ and $\mathcal{DN}$ easily. Moreover, when $n \leq 4$, it is known that $\mathcal{CPP}_n = \mathcal{PSD}_n + \mathcal{NN}_n$ and $\mathcal{CP}_n = \mathcal{DN}_n$ as stated above, and hence those COPs with $n \leq 4$ can be reduced to SDPs.
III. IQC-BASED STABILITY ANALYSIS OF RNN WITH RELU

A. Basics of RNN and Stability

Let us consider the dynamics of the discrete-time RNNs typically described by

\[
G : \begin{cases}
  x(k+1) = \Lambda x(k) + W_{in}w(k) + v(k), \\
  z(k) = W_{out}x(k), \\
  w(k) = \Phi(z(k) + s(k)).
\end{cases}
\]

(5)

Here, \( x \in \mathbb{R}^n \) is the state and \( \Lambda \in \mathbb{R}^{n \times n}, W_{in} \in \mathbb{R}^{m \times n}, W_{out} \in \mathbb{R}^{p \times m} \) are constant matrices with \( \Lambda \) being Schur-Cohn stable. We assume \( x(0) = 0 \). On the other hand, note that \( s : [0, \infty) \rightarrow \mathbb{R}^m \) and \( v : [0, \infty) \rightarrow \mathbb{R}^n \) are external input signals and \( \Phi : \mathbb{R}^m \rightarrow \mathbb{R}^m \) is the static activation function typically being nonlinear. The matrices \( W_{in} \) and \( W_{out} \) are constructed from the weightings of the edges in RNN.

In this paper, we consider the typical case where the activation function is the (entrywise) rectified linear unit (ReLU) whose input-output property is given by

\[
\Phi(\xi) = \begin{bmatrix} \phi(\xi_1) & \cdots & \phi(\xi_m) \end{bmatrix}^T, \\
\phi : \mathbb{R} \rightarrow [0, \infty), \\
\phi(0) = 0 \quad (\phi(0) > 0).
\]

We can readily see that \( \|\Phi\|_2 = 1 \). It should be noted that the system \( G_0 \) essentially makes the feedback loop with the RELU \( \Phi \) where

\[
G_0 := \begin{bmatrix} \Lambda & W_{in} \\ W_{out} & 0 \end{bmatrix}.
\]

(7)

Since here we are dealing with nonlinear systems, it is of prime importance to clarify the definition of "stability." The definition we employ for the analysis of RNN is as follows.

**Definition 2:** [5] (Finite Gain \( l_2 \) Stability) An operator \( H : l_{2e} \ni u \rightarrow y \in l_{2e} \) is said to be finite gain \( l_2 \) stable if there exists a nonnegative constant \( \gamma \) such that \( \|y_t\|_2 \leq \gamma\|u_t\|_2 \) holds for any \( u \in l_{2e} \) and \( t \in [0, \infty) \).

In the following, we analyze the finite gain \( l_2 \) stability of the operator in RNN with respect to the input \( [s^T\ v^T]^T \in l_{2e} \) and the output \( [z^T\ w^T]^T \in l_{2e} \). Note that the feedback connection in the RNN is well-posed since its dynamics is given by the state-space equation (5). We also note that we implicitly use the causality of \( G \) and \( \Phi \) in the following.

B. IQC-Based Basic Stability Condition

It is known that the framework of Integral Quadratic Constraint (IQC) [8] is helpful in capturing the nonlinearity in feedback systems and obtaining less conservative results for stability analysis. The basic IQC-based stability condition for RNN with RELU can be summarized by the next theorem.

**Theorem 1:** For any input signal \( \xi \in l_{2e} \) and output signal \( \zeta \in l_{2e} \) of RELU \( \Phi \) such that \( \zeta = \Phi \xi \), suppose \( \Pi \in \mathbb{R}^{2m \times 2m} \) satisfies the time-domain (discrete-time version of) IQC given by

\[
\sum_{k=0}^{T} \begin{bmatrix} \xi(k) \\ \zeta(k) \end{bmatrix}^T \Pi \begin{bmatrix} \xi(k) \\ \zeta(k) \end{bmatrix} \geq 0
\]

(8)

for any \( \tau \in [0, \infty) \). Then, the RNN given by (5) with RELU \( \Phi \) given by (6) is finite-gain \( l_2 \) stable if there exist \( P \in \mathcal{PS}_{D_2} \) and \( S \in \mathbb{R}^{m \times m} \) such that

\[
\begin{bmatrix}
-\mathbf{P} & v_1 & w_1 \\
0 & -\mathbf{S} & 0 \\
v_1^T & 0 & 0
\end{bmatrix} + \begin{bmatrix}
\bar{\mathbf{A}} & \mathbf{W}_{in} \\
0 & 0 \\
\mathbf{W}_{out} & 0
\end{bmatrix} \begin{bmatrix}
\mathbf{P} & 0 \\
-\mathbf{S} & 0 \\
0 & 0
\end{bmatrix} \begin{bmatrix}
\bar{\mathbf{A}} & \mathbf{W}_{in} \\
0 & 0 \\
\mathbf{W}_{out} & 0
\end{bmatrix}^T \leq 0.
\]

(9)

**Proof of Theorem 1** Suppose (9) holds with \( P = \tilde{P} \in \mathcal{PS}_{D_2} \) and \( S = \tilde{S} \in \mathbb{R}^{m \times m} \). Then, it is very clear that there exist \( \varepsilon > 0 \) and \( \nu > 0 \) such that

\[
M(\tilde{P}, \varepsilon, \nu) := \begin{bmatrix}
-\mathbf{P} + \varepsilon^2 \mathbf{W}_{out} & \mathbf{W}_{out} \\
0 & -\tilde{S} \end{bmatrix} \begin{bmatrix}
\mathbf{P} & 0 \\
-\mathbf{S} & 0
\end{bmatrix} \begin{bmatrix}
-\mathbf{P} + \varepsilon^2 \mathbf{W}_{out} & \mathbf{W}_{out} \\
0 & -\tilde{S} \end{bmatrix}^T + (\nu^T \begin{bmatrix}
\mathbf{W}_{out} \\
\mathbf{I}_m
\end{bmatrix} + (\nu^T \begin{bmatrix}
\mathbf{W}_{out} \\
\mathbf{I}_m
\end{bmatrix})^T \leq 0
\]

(10)

Then, along the trajectory of the RNN for the input signals \( v \in l_{2e} \) and \( s \in l_{2e} \), we have

\[
\begin{bmatrix}
x(k) \\ w(k) \\ v(k) \\ s(k)
\end{bmatrix}^T M(\tilde{P}, \varepsilon, \nu) \begin{bmatrix}
x(k) \\ w(k) \\ v(k) \\ s(k)
\end{bmatrix} \leq 0 \quad (k = 0, 1, \cdots)
\]

or equivalently,

\[
\varepsilon^2 \begin{bmatrix}
\mathbf{z}(k)^T & 0
\end{bmatrix} \begin{bmatrix}
\mathbf{w}(k) \\ \mathbf{s}(k)
\end{bmatrix} + \begin{bmatrix}
\mathbf{w}(k) \\ \mathbf{s}(k)
\end{bmatrix} \begin{bmatrix}
\mathbf{z}(k) \\ \mathbf{s}(k)
\end{bmatrix} \leq 0
\]

(11)

\[
(k = 0, 1, \cdots)
\]

Here, since \( \|\Phi\|_2 = 1 \) and \( \tilde{S} \in \mathbb{R}^{m \times m} \), we have

\[
(\mathbf{z}(k) + \mathbf{s}(k))^T \tilde{S} \mathbf{z}(k) + \mathbf{s}(k) \leq \mathbf{w}(k)^T \tilde{S} \mathbf{w}(k) \geq 0
\]

and hence

\[
\varepsilon^2 \begin{bmatrix}
\mathbf{z}(k)^T & 0
\end{bmatrix} \begin{bmatrix}
\mathbf{w}(k) \\ \mathbf{s}(k)
\end{bmatrix} + \begin{bmatrix}
\mathbf{w}(k) \\ \mathbf{s}(k)
\end{bmatrix} \begin{bmatrix}
\mathbf{z}(k) \\ \mathbf{s}(k)
\end{bmatrix} \leq 0
\]

(12)

\[
(k = 0, 1, \cdots)
\]

By summing up the above inequality up to \( k = \tau \), we have

\[
x(\tau + 1)^T \tilde{P} x(\tau + 1) + \varepsilon^2 \sum_{k=0}^{\tau} \begin{bmatrix}
\mathbf{z}(k)^2 \\ \mathbf{w}(k)^2 \\ \mathbf{s}(k)^2
\end{bmatrix} \leq \mathbf{v}(\tau)^T \mathbf{v}(\tau) + \sum_{k=0}^{\tau} \|s(k)\|_2^2
\]

(13)

Since \( \tilde{P} \in \mathcal{PS}_{D_2} \) and since (8) holds, we can readily conclude from the above inequality that

\[
\|z_\tau\|_2^2 \leq \frac{\mu^2}{\varepsilon^2} \left( \|v_\tau\|_2^2 + \|s_\tau\|_2^2 \right)
\]

or equivalently,

\[
\|z_\tau\|_2^2 \leq \frac{\mu}{\varepsilon} \left\| \begin{bmatrix}
v_\tau \\ s_\tau
\end{bmatrix} \right\|_2.
\]
With this inequality and
\[ \|w_r\|_2 = \|\Phi(z + s)\|_2 = \|\Phi(z + s)\|_2 \leq \|\Phi(z + s)\|_2 + \|s_r\|_2 = \|s_r\|_2, \]
we arrive at the conclusion that
\[ \left\| \begin{bmatrix} z_r \\ w_r \end{bmatrix} \right\|_2 \leq \sqrt{\frac{\nu^2}{\varepsilon} + 2} \|s_r\|_2, \]
holds for any \( v \in l_{2e}, s \in l_{2e}, \) and \( \tau \in [0, \infty) \). This completes the proof. ■

Remark 1: Since \( G_0 \) defined in (7) makes the feedback loop with \( \Phi \), and since \( \|\Phi\|_2 = 1 \), it is very clear that the small gain condition \( \|G_0\|_2 < 1 \) is a sufficient condition for the stability of the RNN with the ReLU. In this sense, it is not hard to see that the ReLU \( \Phi \) satisfies \( \|\Phi(z) - \Phi(z)\|_2 \) for any \( D \in D_{+, \ast} \). Therefore the scaled small gain condition \( \|D^{-1}G_0D\|_2 < 1 \) with \( D \in D_{+, \ast} \) is also a sufficient condition for the stability. It should be noted that (9) with \( D \) with \( \Pi = 0 \) corresponds to the scaled small gain condition, and that (10) with \( \Pi = 0 \) and \( S = I_m \) corresponds to the small gain condition [5]. In this sense, the IQC-based stability condition in Theorem 1 encompasses these basic stability conditions.

IV. CONCRETE MULTIPLIERS CAPTURING THE PROPERTIES OF RELU

A. Zames-Falb Multiplier

In this section, we summarize the arguments of [10] on the discrete-time Zames-Falb multipliers [9]. By following [10], we first introduce the following definitions.

Definition 3: [10] Let \( \mu \leq 0 \leq \nu \). Then the nonlinearity \( \phi : \mathbb{R} \rightarrow \mathbb{R} \) is sloperestricted, in short \( \phi \in \text{slope}(\mu, \nu) \), if \( \phi(0) = 0 \) and
\[ \mu \leq \frac{\phi(x) - \phi(y)}{x - y} \leq \sup_{x \neq y} \frac{\phi(x) - \phi(y)}{x - y} < \nu \]
for all \( x, y \in \mathbb{R}, x \neq y \). On the other hand, the nonlinearity \( \phi \) is said to be sector-bounded if
\[ (\phi(x) - \alpha x)(\phi(x) - \beta x) \leq 0 \quad (\forall x \in \mathbb{R}) \]
for some \( \alpha \leq 0 \leq \beta \). This is expressed as \( \phi \in \text{sec}[\alpha, \beta] \).

The main result of [10] on the discrete-time Zames-Falb multipliers for slope-restricted nonlinearities can be summarized by the next lemma.

Lemma 1: [10] For a given nonlinearity \( \phi \in \text{slope}(\mu, \nu) \) with \( \mu \leq 0 \leq \nu \), let us define \( \Phi : \mathbb{R}^m \rightarrow \mathbb{R}^m \) by the first equation in (6). Assume \( M \in D_{HD}^{m} \). Then we have
\[ (*)^T \left[ \begin{array}{cccc} 0 & M^T & 0 & 0 \\ \mu & 0 & -I_m & 0 \\ -\mu & I_m & 0 & 0 \\ 0 & 0 & 0 & I_m \end{array} \right] \left[ \begin{array}{c} x \\ \phi(x) \end{array} \right] \geq 0 \quad (\forall x \in \mathbb{R}^m). \]

From this key lemma and the fact that the ReLU \( \phi : \mathbb{R} \rightarrow \mathbb{R} \) satisfies \( \phi \in \text{slope}(0, 1) \), we can obtain the next result on the Zames-Falb multiplier for the ReLU given by (6).

Corollary 1: Let us define
\[ \Pi_{ZF} := \left\{ \Pi \in \mathbb{S}^m : \Pi = (\ast)^T \left[ \begin{array}{cccc} 0 & M^T & 0 & 0 \\ \mu & 0 & -I_m & 0 \\ -\mu & I_m & 0 & 0 \\ 0 & 0 & 0 & I_m \end{array} \right], M \in D_{HD}^{m} \right\}. \]
Then, \( \Pi \in \Pi_{ZF} \) is a valid multiplier that satisfies (8) for the ReLU \( \Phi \) given by (6).

B. Polytopic Bounding Multiplier

The polytopic bounding multipliers are useful to capture the properties of sector-bounded nonlinearities. To represent them in compact fashion, let us define
\[ \Pi_{pol}^{\ast}[\alpha, \beta] := \left\{ \Pi \in \mathbb{S}^{2m} : (*)^T \left[ \begin{array}{c} I_m \end{array} \right] \geq 0 \quad (\forall \Delta \in \mathbb{D}^{m}[\alpha, \beta]) \right\}. \]

The following lemma provides the polytopic bounding multipliers for sector-bounded nonlinearities.

Lemma 2: [10] For a given nonlinearity \( \phi \in \text{slope}[\alpha, \beta] \) with \( \alpha \leq 0 \leq \beta \), let us define \( \Phi : \mathbb{R}^m \rightarrow \mathbb{R}^m \) by the first equation in (6). Assume \( \Pi \in \Pi_{pol}^{\ast}[\alpha, \beta] \). Then we have
\[ (*)^T \left[ \begin{array}{c} x \\ \Phi_{m} (x) \end{array} \right] \geq 0 \quad (\forall x \in \mathbb{R}^m). \]

As also stated in [10], it is hard to check whether \( \Pi \in \Pi_{pol}^{\ast}[\alpha, \beta] \) holds since \( \Pi_{pol}^{\ast}[\alpha, \beta] \) is characterized by infinitely many constraints. To get around this difficulty, we employ a primitive but numerically tractable inner approximation of \( \Pi_{pol}^{\ast}[\alpha, \beta] \) as follows:
\[ \Pi_{pol}[\alpha, \beta] := \left\{ \Pi = \left[ \begin{array}{cc} X & Y \\ Y^T & Z \end{array} \right] \in \mathbb{S}^{2m} : \right. \]
\[ (*)^T \left[ \begin{array}{c} I_m \end{array} \right] > 0 \quad (\forall \Delta \in \mathbb{D}^{m} \text{sec}[0, 1], Z_{ii} \leq 0 \quad (i = 1, \cdots, m) \right\}. \]

From this inner approximation and the fact that the ReLU \( \phi : \mathbb{R} \rightarrow \mathbb{R} \) satisfies \( \phi \in \text{slope}[0, 1] \), we can obtain the next result that provides the polytopic bounding multiplier for the ReLU given by (6).

Corollary 2: Let us define
\[ \Pi_{pol} := \left\{ \Pi = \left[ \begin{array}{cc} X & Y \\ Y^T & Z \end{array} \right] \in \mathbb{S}^{2m} : \right. \]
\[ (*)^T \left[ \begin{array}{c} I_m \end{array} \right] > 0 \quad (\forall \Delta \in \mathbb{D}^{m} \text{sec}[0, 1], Z_{ii} \leq 0 \quad (i = 1, \cdots, m) \right\}. \]

Then, \( \Pi \in \Pi_{pol} \) is a valid multiplier that satisfies (8) for the ReLU \( \Phi \) given by (6).

We finally note that the denomination “polytopic bounding” comes from the historical reason that the multipliers in (11) and (12) have been used to handle parametric uncertainties in polytopes in the context of robust control [17], [18].

Remark 2: Even though we restrict our attention to the static Zames-Falb multiplier of the form (10) in Corollary 1, it is true that the dynamical finite impulse response (FIR) Zames-Falb multipliers are also investigated in [10] in frequency domain. We do not pursue such a direction in this paper mainly because the novel copositive multipliers, to be introduced in the next subsection, rely on the analysis in time-domain. However, we have a prospect that the extension similar to the FIR multipliers in [10] can also be achieved in time-domain by means of discrete-time system lifting [19]. Such an extension, and mutual relationship with the FIR multipliers are currently under investigation. Still, we have already obtained related results on the use of the discrete-time system lifting in [6].

Remark 3: As clarified exhaustively in [10], the polytopic bounding multiplier encompasses some existing and frequently used multipliers. For instance, the following so-called diagonally structured multiplier has been often
employed to handle sector-bounded nonlinearities $\Phi$ in Lemma~2.

$$\Pi_{b[a, \beta]} := \left\{ \Pi \in \mathbb{S}^{2m} : \Pi = \begin{bmatrix} \alpha \beta D & \alpha + \beta \frac{D}{2} \\ \alpha + \beta \frac{D}{2} & D \end{bmatrix}, D \in \mathbb{D}^{m}_{++} \right\}. $$

Then it is very clear that $\Pi_{b[a, \beta]} \subset \Pi_{pol[a, \beta]} \subset \Pi_{pol[a, \beta]}$. Since the effectiveness of the Zames-Falb multipliers is also widely recognized, we could say that $\Pi \in \Pi_{pol} + \Pi_{ZF}$ is the most up-to-date, effective, and numerically tractable existing (static) multiplier to handle the ReLU.

C. Novel Copositive Multiplier

It has been shown recently in [20] that the input-output relationship of the ReLU given by (6) can be fully captured in the copositive cone $\Pi_{COP}$ because the cone $\Pi_{PSD}$ on the standard positive semidefinite cone do not conform to the IQC framework if we merely rely on the cone $\Pi_{PSD}$ has no functionality to distinguish nonnegative vectors in the quadratic form. To get around this difficulty, we employ copositive cone $\Pi_{COP}$ and introduce the copositive multipliers. This result is summarized in the next theorem.

Theorem 2: Let us define

$$\Pi_{COP} := \Pi \in \mathbb{S}^{2m}, \Pi = (\cdot)^T Q \begin{bmatrix} -I_m & 0 \\ 0 & I_m \end{bmatrix}, Q \in \Pi_{COP_{2m}}. $$

Then, $\Pi \in \Pi_{COP}^*$ is a valid multiplier that satisfies (9) for the ReLU $\Phi$ given by (6).

Remark 4: As stated in Section II, it is hard to check whether $Q \in \Pi_{COP_{2m}}$ holds in (15) and hence the copositive multiplier (15) is intractable in general. To get around this difficulty, we apply inner approximation to the copositive cone $\Pi_{COP}$ and define

$$\Pi_{COP} := \Pi, \Pi = \Pi \in \Pi_{COP}^* \subset \Pi_{COP} \subset \Pi_{pol}^* \subset \Pi_{pol} \subset \Pi_{pol[a, \beta]}. $$

Then, it is clear from (6) that $\Pi_{COP} \subset \Pi_{pol}^*$ and hence $\Pi \in \Pi_{COP}$ is a valid multiplier that satisfies (9) for the ReLU $\Phi$ given by (6). In particular, $\Pi_{COP} = \Pi_{COP}$ holds if $m \leq 2$.

It should be noted that checking $Q \in \Pi_{PSD_{2m}} + \Pi_{NN_{2m}}$ is numerically tractable since this is essentially a positive semidefinite constraint.

Remark 5: In relation to the copositive multiplier (16), let us consider its special case given by

$$\Pi_{COP,0} := \Pi \in \mathbb{S}^{2m}, \Pi = (\cdot)^T Q \begin{bmatrix} -I_m & 0 \\ 0 & I_m \end{bmatrix}, Q \in \Pi_{PSD_{2m}} + \Pi_{NN_{2m}}. $$

Then, we can see from (6) that the condition (9) with $\Pi \in \Pi_{COP,0}$ is a sufficient condition for the $l_{2+}$-induced norm-based scaled small gain condition $\|D^{-1} G_0 D\|_{2+} < 1$ with $D \in \mathbb{D}^{m}_{++}$. Since the ReLU only returns nonnegative signals, we intuitively deduce that $\|D^{-1} G_0 D\|_{2+} < 1$ could be a sufficient condition for the stability. We have validated this as the main result in [6], providing also the numerically verifiable condition (9) with $\Pi \in \Pi_{COP,0}$. Since $\Pi_{COP,0}$ does hold, we can conclude that the present result encompasses the main result of [6] as a special case.

Remark 6: The treatment of nonnegative signals is the core for the analysis of positive systems, and to actively use the nonnegativity in the analysis the integral linear constraints are introduced in [22]. However, to build an effective stability analysis method of RNNs upon the powerful IQC approach with existing multipliers, we have to capture the nonnegativity of the signals in quadratic form. This is the reason why we introduced copositive multipliers.

V. NUMERICAL EXAMPLES

In (5), let us consider the case $\Lambda = 0$, $W_{out} = I_6$ and $W_{in} = \begin{bmatrix} 0.29 & -0.04 & 0.02 + a & -0.35 & -0.05 & -0.12 \\ -0.29 & -0.24 & -0.01 & 0.12 & -0.13 & 0.18 \\ -0.50 & b & 0.23 & 0.40 & -0.28 & -0.80 \\ 0.14 & -0.27 & -0.15 & 0.13 & -0.47 & -0.28 \\ -0.10 & -0.10 & 0.08 & 0.14 & -0.22 & 0.50 \\ -0.11 & -0.28 & -0.21 & -0.14 & -0.09 & 0.20 \end{bmatrix}$.

For $(a, b) = (0, 0)$, we see $\|G_0\|_2 = 0.9605$. Here we examined the finite gain $l_2$ stability over the (time-invariant) parameter variation $a \in [-2, 2]$ and $b \in [-10, 10]$. This example is exactly the same as that of [6] except for the range of the parameter variation.

We tested the following stability conditions:

Test I (SSG): Find $P \in \Pi_{PSD_n}$, $S \in \mathbb{D}^{m}_{++}$ such that (9) holds with $\Pi = 0$.

Test II (l$_2$-SSG): Find $P \in \Pi_{PSD_n}$, $S \in \mathbb{D}^{m}_{++}$, and $\Pi \in \Pi_{COP,0}$ such that (9) holds.

Test III (SSG+ZF+PolB): Find $P \in \Pi_{PSD_n}$, $S \in \mathbb{D}^{m}_{++}$, and $\Pi \in \Pi_{ZF} \cap \Pi_{pol}$ such that (9) holds.

Test IV (SSG+ZF+PolB+COP): Find $P \in \Pi_{PSD_n}$, $S \in \mathbb{D}^{m}_{++}$, and $\Pi \in \Pi_{ZF} \cap \Pi_{pol} \cap \Pi_{COP}$ such that (9) holds.

It is very clear that if Test I is feasible then Tests II and III are, and if Test III is feasible then Test IV is. However, there is no theoretical inclusion relationship between Test II and Test III. Test I corresponds to the scaled small gain condition with the standard $l_2$ induced norm, while Test II corresponds to the scaled small gain condition with the $l_{2+}$ induced norm. These have been already implemented in [6], but we retested them since we changed the range of the parameter variation.

In Fig. 1, we plot $(a, b)$ for which the RNN is proved to be stable by Tests I and II. Both Tests turned out to be feasible for $(a, b)$ in the green region, whereas only Test II turned out to be feasible for $(a, b)$ in the magenta region. On the other hand, in Fig. 2, both Tests III and IV turned out to be feasible for $(a, b)$ in the red region, whereas only Test IV turned out to be feasible for $(a, b)$ in the blue region. From both figures, we can confirm the effectiveness of the copositive multipliers. As for the comparison between Tests II and III, Test III turned out to be feasible in much larger region than that of Test II, but there is no strict inclusion relationship between them. In fact, for $(a, b) = (1, 0, 1.4)$, Test II and III turned out to be feasible and infeasible, respectively.
In this paper, we dealt with the stability analysis of the RNN with the ReLU by means of the IQC framework. By actively using the nonnegativity property of the ReLU, we newly introduced the copositive multipliers. We showed that we can employ copositive multipliers (or their inner approximation) together with existing multipliers such as Zames-Falb multipliers and polytopic bounding multipliers, and this directly enabled us to ensure that the introduction of copositive multipliers leads to better (no more conservative) results. By numerical examples, we illustrated the effectiveness of the copositive multipliers.

In the present paper and [6], we converted a COP to an SDP by simply replacing \( \mathcal{COP} \) by \( \mathcal{PSSD + N}_N \). However, this treatment is conservative. In this respect, Lasserre [23] and Klerk and Pasechnik [24] have already shown independently how to construct a hierarchy of SDPs to solve COP in an asymptotically exact fashion, but the size of SDPs grows very rapidly. This is prohibitive to deal with realistic, larger size networks. To get around this difficulty, we plan to rely on efficient first-order methods to solve the specific conic relaxations arising from polynomial optimization problems with sphere constraints [25].
