ON A SEQUENCE OF GROTHENDIECK GROUPS

ÁDÁM GYENGE

Abstract. We show that a well-known exact sequence in K-theory for quotients of triangulated categories descends to numerical K-groups provided that the category, the quotient and the category we take the quotient with has a numerical K-group, and if either the quotient functor preserves compactness or the K-group of the quotient is torsion-free.

1. Introduction

Let $\mathcal{T}$ be a triangulated category, $\mathcal{S}$ a subcategory and let $\mathcal{T}/\mathcal{S}$ be the Verdier quotient. Then there is an exact sequence of ordinary Grothendieck groups [7, Proposition VIII.3.1.]:

$$K_0(\mathcal{S}) \overset{i^*}{\rightarrow} K_0(\mathcal{T}) \overset{q^*}{\rightarrow} K_0(\mathcal{T}/\mathcal{S}) \rightarrow 0$$

where $i^*$ is induced by the embedding functor $i: \mathcal{S} \subset \mathcal{T}$ and $q^*$ is induced by the quotient functor $q: \mathcal{T} \rightarrow \mathcal{T}/\mathcal{S}$.

The numerical Grothendieck group is the quotient of the usual Grothendieck group by the kernel (or radical) of the Euler form. When exists, it often gives a more tractable invariant than the classical K-group. For example, when $\mathcal{T}$, or more precisely its dg enhancement, is smooth and proper, then the numerical Grothendieck group is a finitely generated free abelian group.

In this paper we show that the sequence (1.1) descends to numerical Grothendieck groups under quite general circumstances.

Theorem 1.1 (Theorem 4.7). Let $\mathcal{T}$ be a triangulated category and $\mathcal{S}$ a strictly full triangulated subcategory of $\mathcal{T}$. Assume that the numerical Grothendieck groups of $\mathcal{T}$, $\mathcal{S}$ and $\mathcal{T}/\mathcal{S}$ all exist. Suppose moreover that $q$ or, equivalently, $i$ preserves compactness. Then there is an exact sequence

$$K_0^{\text{num}}(\mathcal{S}) \rightarrow K_0^{\text{num}}(\mathcal{T}) \rightarrow K_0^{\text{num}}(\mathcal{T}/\mathcal{S}) \rightarrow 0$$

of numerical Grothendieck groups.

In the main body of the paper, for simplicity, we work in the context of derived categories of DG categories. However, in the proof of Theorem 1.1 we do not actually refer to the DG enhancements, so the claims hold in the above generality provided the necessary functors exist.

We discuss first a recollement arising from quotients. For derived categories of (quasi-compact and quasi-separated) schemes this recollement has appeared in [11]. For DG categories the statements are also known to experts as they follow implicitly from [6] Proposition 4.6 (ii)]. In the background, recollements are closely related to semiorthogonal decompositions, and DG quotients induce such a decomposition under quite general circumstances. Our contribution is the extension of the methods of [11] to the DG setting, hence giving an alternative proof of [6] Proposition 4.6 (ii)], a detailed description of the relevant functors as well as an application of the results on numerical K-groups.

After preliminary definitions and a review of the basic structures we show:

Key words and phrases. numerical K-group, recollement, Drinfeld quotient, Calabi-Yau triple.
2.1. DG-categories and DG-modules. Let $k$ be a field. A DG-category $\mathcal{A}$ is a category enriched over the monoidal category $\text{Mod-}k$ of complexes of $k$-modules, that is, a category where the morphism spaces are objects of $\text{Mod-}k$ and the compositions are morphisms of dg $k$-modules.

All functors from now on are assumed to be DG. A (right) module $E$ over $\mathcal{A}$ is a functor $E : \mathcal{A}^{\text{opp}} \to \text{Mod-}k$. For any $a \in \mathcal{A}$ we write $E_a$ for the complex $E(a) \in \text{Mod-}k$, the fiber of $E$ over $a$. We write $\text{Mod} - \mathcal{A}$ for the DG-category of (right) $\mathcal{A}$-modules. Similarly, the $\mathcal{A}$-module $F$ is a functor $F : \mathcal{A} \to \text{Mod-}k$. We write $aF$ for the fiber $F(a) \in \text{Mod-}k$ of $F$ over $a \in \mathcal{A}$ and $\text{Mod} - \mathcal{A}$-Mod for the DG-category of left $\mathcal{A}$-modules.

Given another DG-category $\mathcal{B}$, an $\mathcal{A}$-$\mathcal{B}$-bimodule $M$ is an $\mathcal{A}^{\text{opp}} \otimes_k \mathcal{B}$-module. For any $a \in \mathcal{A}$ and $b \in \mathcal{B}$ we write $aM$ in $\text{Mod-}\mathcal{B}$ for the fiber $M(a, -)$ of $M$ over $a$, $Mb \in \text{Mod-}k$ for the fiber of $M$ over $(a, b)$. We write $\text{Mod} - \mathcal{A}$-$\mathcal{B}$-Mod for the DG-category of $\mathcal{A}$-$\mathcal{B}$-bimodules. The categories $\text{Mod} - \mathcal{A}$ and $\mathcal{A}$-$\text{Mod}$ of right and left $\mathcal{A}$-modules can therefore be considered as the categories of $k$-$\mathcal{A}$- and $\mathcal{A}$-$k$-bimodules. For any DG-category $\mathcal{A}$, we write $\mathcal{A}$ for the diagonal $\mathcal{A}$-$\mathcal{A}$-bimodule defined by $aA_b = \text{Hom}_\mathcal{A}(a, b)$ for all $a, b \in \mathcal{A}$ with morphisms of $\mathcal{A}$ and $\mathcal{B}$ acting by pre- and post-composition respectively:

$$\mathcal{A}(\alpha \otimes \beta) = (-1)^{\deg(\beta) \cdot \deg(\alpha)} \alpha \circ (-) \circ \beta, \quad \forall \alpha \in \text{Hom}_\mathcal{A}(a, a'), \beta \in \text{Hom}_\mathcal{A}(b', b).$$
DG-bimodules over DG-categories admit a closed symmetric monoidal structure. That is, they admit a tensor product and an internal Hom. Given three DG-categories \(A, B\) and \(C\), there exist functors

\[
(-) \otimes_B (-) : A\text{-Mod}-B \otimes B\text{-Mod}-C \to A\text{-Mod}-C,
\]

\[
\text{Hom}_B(-, -) : A\text{-Mod}-B \otimes C\text{-Mod}-B \to C\text{-Mod}-A,
\]

\[
\text{Hom}_B(-, -) : B\text{-Mod}-A \otimes B\text{-Mod}-C \to A\text{-Mod}-C,
\]

where

\[
M \otimes_B N = \text{Coker}(M \otimes_k B \otimes_k N \xrightarrow{\text{act} \otimes \text{id} - \text{id} \otimes \text{act}} M \otimes_k N),
\]

while \(c (\text{Hom}_B(M, N))_a = \text{Hom}_B(aM, cN)\) for \(M, N\) with right \(B\)-action, and \(a (\text{Hom}_B(M, N))_c = \text{Hom}_B(M_c, N_a)\) for \(M, N\) with left \(B\)-action, cf. [1] Section 2.1.5 for details.

2.2. The derived category of a DG-category. Let \(A\) be a DG-category. Its homotopy category \(H^0(A)\) is defined as the \(k\)-linear category whose objects are the same as those of \(A\) and whose Hom spaces are \(H^0(-)\) of the Hom complexes of \(A\).

The category \(H^0(\text{Mod-}A)\) has a natural structure of a triangulated category defined levelwise in \(\text{Mod-}k\). That is, the homotopy category \(H^0(\text{Mod-}k)\) of complexes of \(k\)-modules has a well-known triangulated structure, and we define one on \(H^0(\text{Mod-}A)\) by using that structure in the fibers over each \(a \in A\). A DG-category \(A\) is pretriangulated if \(H^0(A)\) is a triangulated subcategory of \(H^0(\text{Mod-}A)\) under the Yoneda embedding.

Given a DG-category \(A\) with a full subcategory \(C \subset A\) there exists the Drinfeld quotient \(A/C\) (see [2]). It is constructed by formally adding for every \(c \in C\) a degree \(-1\) contracting homotopy \(\xi_c\), with \(d\xi_c = \text{id}_c\). When \(A\) and \(C\) are pretriangulated, one recovers the Verdier quotient as \(H^0(A/C) \simeq H^0(A)/H^0(C)\).

An \(A\)-module \(E\) is acyclic if \(E_a\) is an acyclic complex for all \(a \in A\). We denote by \(\text{Ac}\, A\) the full subcategory of \(\text{Mod-}A\) consisting of acyclic modules. A morphism of \(A\)-modules is a quasi-isomorphism if it is a quasi-isomorphism levelwise in \(\text{Mod-}k\) for every \(a \in A\). The derived category \(D(A)\) is the localisation of \(H^0(\text{Mod-}A)\) by quasi-isomorphisms, constructed as the Verdier quotient \(H^0(\text{Mod-}A)/\text{Ac}\, A\).

The derived category can be constructed on the DG level. An \(A\)-module \(P\) is \(h\)-projective (resp. \(h\)-flat) if \(\text{Hom}_A(P, C)\) (resp. \(P \otimes_A C\)) is an acyclic complex of \(k\)-modules for any acyclic \(C \in \text{Mod-}A\) (resp. \(C \in \text{Mod-}A\)). We denote by \(P(\mathcal{A})\) the full subcategory of \(\text{Mod-}A\) consisting of \(h\)-projective modules. It follows from the definition that in \(P(\mathcal{A})\) every quasi-isomorphism is a homotopy equivalence, and therefore we have \(D(\mathcal{A}) \simeq H^0(P(\mathcal{A}))\). Alternatively, one uses Drinfeld quotients: \(D(\mathcal{A}) = H^0(\text{Mod-}A/A_c\, A)\).

An object \(a\) of triangulated category \(\mathcal{T}\) is compact if \(\text{Hom}_\mathcal{T}(a, -)\) commutes with finite direct sums. We write \(D_c(\mathcal{A})\) for the full subcategory of \(D(\mathcal{A})\) consisting of all compact objects. We say that an \(A\)-module \(E\) is perfect if the class \(E \in D(\mathcal{A})\) is in \(D_c(\mathcal{A})\).

Let \(A\) and \(B\) be DG categories and let \(M\) be an \(A\)-\(B\)-bimodule. We say that \(M\) is \(A\)-perfect (resp. \(B\)-perfect) if it is perfect levelwise in \(A\) (resp. \(B\)). That is, \(aM\) (resp. \(Mb\)) is a perfect module for all \(a \in A\) (resp. \(b \in B\)). Similarly, for other properties of modules such as \(h\)-projective, \(h\)-flat, or representable.

Let \(A\) be a DG-category. We say that \(A\) is smooth if the diagonal bimodule \(A\) is perfect as an \(A\)-\(A\)-bimodule. We say that \(A\) is proper if the total cohomology of each of its Hom-complexes is finitely-generated and \(D(\mathcal{A})\) is compactly generated. See [21] Section 2.2 for further details on these two notions.

2.3. Restriction and extension of scalars. Let \(A\) and \(B\) be two DG-categories and let \(M\) be an \(A\)-\(B\)-bimodule. Moreover, let \(A'\) and \(B'\) be another two DG-categories and let \(f: A' \to A\) and \(g: B' \to B\) be DG-functors. Define the restriction of scalars of \(M\) along \(f\) and \(g\) to be the \(A'\)-\(B'\)-bimodule \(f_M\) defined as \(M \circ (f \otimes_k g)\). In particular, for any \(a \in A\) and \(b \in B\) we have \(a(f_M)_b = f(a)M_{g(b)}\). We write \(f_M\) and \(M_g\) for \(f_M\) and \(id_M\), respectively.
Let $\mathcal{A}$ and $\mathcal{B}$ be two DG-categories and let $f: \mathcal{A} \to \mathcal{B}$ be a DG-functor. We then have the following three induced functors:

1. The extension of scalars functor
   $$f^*: \text{Mod-} \mathcal{A} \to \text{Mod-} \mathcal{B},$$
   is defined to be $(-) \otimes_{\mathcal{A}} f \mathcal{B}$.

2. The restriction of scalars functor
   $$f_*: \text{Mod-} \mathcal{B} \to \text{Mod-} \mathcal{A},$$
   is defined to be $(-) \otimes_{\mathcal{B}} f \mathcal{B}$. It sends each $E \in \text{Mod-} \mathcal{B}$ to its restriction $E_f \in \text{Mod-} \mathcal{A}$, and therefore sends acyclic modules to acyclic modules.

3. The twisted extension of scalars functor
   $$f^!: \text{Mod-} \mathcal{A} \to \text{Mod-} \mathcal{B},$$
   is defined to be $\text{Hom}_{\mathcal{A}}(Bf, -)$.

By Tensor-Hom adjunction $(f^*, f_*)$ and $(f_*, f^!)$ are adjoint pairs of DG-functors. Since $f_*$ preserves acyclic modules it follows that $f^*$ preserves $h$-projective modules and $f^!$ preserves $h$-injective modules. Eventually, we obtain the derived functors (whose derivedness we omit to denote in the rest of the paper):

$$f_* := Lf_*: D(\mathcal{A}) \to D(\mathcal{B}), \quad f_*: D(\mathcal{B}) \to D(\mathcal{A}), \quad f^! := Rf^!: D(\mathcal{A}) \to D(\mathcal{B}).$$

Again these form an adjoint triple.

3. Recollement

The notion of a recollement of triangulated categories was introduced in [5, Section 1.4]. Let $\mathcal{S}$, $\mathcal{T}$ and $\mathcal{Q}$ be triangulated categories. A recollement is a diagram of triangulated functors

$$
\begin{array}{ccc}
\mathcal{Q} & \xrightarrow{q^*} & \mathcal{T} \\
\downarrow{q_*} & & \downarrow{i_*} \\
\mathcal{T} & \xleftarrow{i^*} & \mathcal{S}
\end{array}
$$

such that

1. $(q^*, q_*), (q_*, q^!), (i^*, i_*), (i_*, i^!)$ are adjoint pairs;
2. $q_*, i^!$ and $i^!$ are fully faithful;
3. the composite of two functors in each row is zero.
4. there are two canonical triangles for each object $X$ of $\mathcal{S}$:
   $$i^!i_*X \to X \to q_*q^*X \to i^*i_*X[1]$$
   and
   $$q^!q_*X \to X \to i^!i_*X \to q^!q_*X[1].$$

We show that a recollement arises from taking a Drinfeld quotient of dg enhanced triangulated categories. Let $\mathcal{I}$ be a strictly full dg subcategory of a DG category $\mathcal{V}$. Denote by $i: \mathcal{I} \to \mathcal{V}$ the inclusion functor and by $q: \mathcal{V} \to \mathcal{V}/\mathcal{I}$ the quotient functor to the Drinfeld quotient.

**Theorem 3.1.** Let $\mathcal{I}$ be a strictly full dg subcategory of $\mathcal{V}$. Then there is a recollement

$$
\begin{array}{ccc}
D(\mathcal{V}/\mathcal{I}) & \xrightarrow{q^*} & D(\mathcal{V}) \\
\downarrow{q_*} & & \downarrow{i_*} \\
D(\mathcal{V}) & \xleftarrow{i^*} & D(\mathcal{I})
\end{array}
$$

In particular $i^*, i^!$ and $q_*$ are fully faithful functors.
Proof. We adapt the proof of [11] Proposition on page 2 to our setting. As \( i^* \) is the inclusion of \( D(I) \) into \( D(V) \) (see [13] Proposition 1.15], it is fully faithful and triangulated. Therefore, \( i_* \) is also triangulated by [10] Lemma 5.3.6. As \( i^* \) sends compact objects to compact objects (see for example the proof of [13] Proposition 1.15], \( i_* \) respects set indexed coproducts by [15] Theorem 5.1]. This is exactly the setting of [14] which gives a recollement on the triple \((\text{Ker}(i_*), D(V), D(I))\).

For \( E \) to be in \( \text{Ker}(i_*) \) means that \( i_* E = 0 \). This holds precisely when \( \text{Hom}_{D(I)}(I, i_* E) \) for all \( I \in I \). But

\[
\text{Hom}_{D(I)}(I, i_* E) = \text{Hom}_{D(V)}(i^* I, E).
\]

As \( i^* \) is fully faithful, this means that \( \text{Ker}(i_*) = D(I)^\perp \), the right orthogonal to \( D(I) \) in \( D(V) \). Then [12] Proposition 4.9.1 (5)] shows that the composition

\[
D(I)^\perp \to D(V) \to D(V)/D(I) = D(V/I)
\]

is an equivalence. \( \square \)

Theorem 3.2. Let \( I \) be a strictly full dg subcategory of \( V \). The following conditions are equivalent:

1. \( V_i \) is a perfect \( I \)-module.
2. \( i_* \) preserves compact objects.
3. \( q_* \) preserves compact objects.
4. \((V/I)_q \) is a perfect \( V \)-module.

If this is the case, there is a “half recollement”

\[
\begin{array}{ccc}
D_c(V/I) & \xrightarrow{q^*} & D_c(V) \\
\xleftarrow{i_*} & & \xrightarrow{i_*} \\
D_c(I) & \xrightarrow{i^*} & D_c(V/I)
\end{array}
\]

Proof. First we show the equivalence of (1) and (2). Our setting satisfies the assumptions for Brown representability [15] Theorem 4.1. By [15] Theorem 5.1], \( i_* : D(V) \to D(I) \) preserves compactness if and only if its right adjoint \( i^*(\cdot) = R\text{Hom}_I(V_i, \cdot) \) preserves arbitrary direct sums. As the \( h \)-injective resolution of a direct sum is the direct sum of the \( h \)-injective resolution of the summands, \( R\text{Hom}_I(V_i, \cdot) \) preserves arbitrary direct sums if and only if \( \text{Hom}_I(V_i, \cdot) \) preserves arbitrary direct sums. By definition, this happens if \( V_i \) is a perfect \( I \)-module.

The proof of the equivalence of (3) and (4) is similar.

Finally, the equivalence of (2) and (3) follows from [3] Lemma 2.2], because the derived category of a DG category is compactly generated. \( \square \)

Recall that a functor \( h : T \to Vect \) from an Ext-finite triangulated category \( T \) to the category of vector spaces is called cohomological if it takes exact triangles to long exact sequences. It is of finite type if for every object \( A \in T \), \( \dim \oplus_n h(A[n]) < \infty \). For every object \( A \in T \) the functors \( h_A(\cdot) := \text{Hom}(A, \cdot) \) and \( h^A(\cdot) := \text{Hom}(\cdot, A) \) are finite dimensional cohomological functors by definition. Covariant (resp. contravariant) cohomological functors isomorphic to \( h_A \) (resp. \( h^A \)) are called representable. The category \( T \) is called left (resp. right) saturated if every covariant (resp. contravariant) cohomological functor of finite type is representable. Right saturatedness gives a sufficient condition for the existence of the half recollement of Theorem 3.2.

Lemma 3.3. Let \( I \) be a strictly full dg subcategory of \( V \).

1. If \( D_c(V) \) is right saturated, then \( q_* \) preserves compact objects.
2. If \( D_c(I) \) is right saturated, then \( i_* \) preserves compact objects.
Further, if $f$ (Theorem 1.2, [19, Theorem 1.2]) Proposition 4.4

$$K_f : \text{Lemma 4.5. Let } K(G) \text{ Grothendieck group Suppose that Corollary 4.3.}
$$

$\text{tion 4.24 of [18]. But the proof in fact only uses the existence of the Serre functor.}$

$\chi$ of $F \text{ or}$

Proof. We just prove (1). As adjoint functors are unique up to an isomorphism, it is enough to show that $q^* : D_c(V) \to D_c(V/I)$ has a right adjoint. For any $b \in D_c(V/I)$ consider the functor

$$F_b(a) = \text{Hom}(q^*(a), b).$$

This is a contravariant cohomological functor of finite type. Hence, it is representable by an object $q'_*(b) \in D_c(V)$:

$$F_b(a) = \text{Hom}(a, q'_*(b)).$$

As Hom is functorial in both variables, the correspondence $b \mapsto q'_*(b)$ is also functorial. By the construction, $q'_* \text{ is right adjoint to } q^*$, so it must agree with the restriction of $q_*$ to $D_c(V/I)$.

4. An exact sequence for numerical Grothendieck groups

Consider a dg category $V$. The Grothendieck group $K_0(V) = K_0(D_c(V))$ of $V$ comes equipped with the Euler (or Mukai) pairing

$$[a], [b] \mapsto ([a], [b])_\chi := \chi(\text{Hom}_V(a, b)) = \sum_{n \in \mathbb{Z}} (-1)^n H^n \text{Hom}_V(a, b).$$

Recall that a covariant autoequivalence $S : D_c(V) \to D_c(V)$ is a Serre functor, if there is a bifunctorial isomorphism

$$\text{Hom}(A, B)^* \cong \text{Hom}(B, SA), \quad A, B \in D_c(V).$$

Example 4.1. (1) If $V$ is smooth and proper, then $D_c(V)$ has a Serre functor [2, Section 3].

(2) Let $A$ be a finite-dimensional $k$-algebra of finite global dimension, and $V$ the DG category of right (or left) $A$-modules. Then $D_c(V)$, the bounded derived category of finite-dimensional $A$-modules has a Serre functor.

Proposition 4.2. Suppose that $D_c(V)$ has a Serre functor.

(1) For every pair of objects $a, b$ of $D_c(V)$

$$\langle [a], [b] \rangle_\chi = \langle [b], [Sa] \rangle_\chi = \langle [S^{-1}b], [a] \rangle_\chi$$

where $S$ is the Serre functor on $D_c(V)$.

(2) The left and right kernels of $\chi$ agree.

Proof. For $V$ smooth and proper this statement was proved in Lemma 4.25 and Proposition 4.24 of [18]. But the proof in fact only uses the existence of the Serre functor.

Corollary 4.3. Suppose that $V$ is a DG category such that the left and right kernels of $\chi$ agree (e.g. if $D_c(V)$ has a Serre functor). Then there is a well-defined numerical Grothendieck group $K_{0}^\num(V) := K_0(V)/\ker(\chi)$ of $V$.

Proposition 4.4 ([20, Theorem 1.2], [19, Theorem 1.2]). The numerical Grothendieck group $K_{0}^\num(V)$ is a finitely generated free abelian group.

If $f : A \to B$ is a functor of dg categories, then $f^* : D_c(A) \to D_c(B)$ induces a morphism $K^0(A) \to K^0(B)$.

Lemma 4.5. Let $A, B$ be DG-categories whose numerical Grothendieck group exist, and let $f : A \to B$ be a DG-functor. Then $f^*$ induces a map

$$f^* : K_{0}^\num(A) \to K_{0}^\num(B).$$

Further, if $f$ preserves compactness, then it induces a map

$$f_* : K_{0}^\num(B) \to K_{0}^\num(A).$$
Proof. As the Euler pairing is defined in terms of Hom-spaces in the derived category, it is compatible with standard derived adjunctions. For any $a \in D_c(A)$ and for any $b \in D_c(B)$ we have

$$\chi(f^*(a), b) = \sum (-1)^i \dim \text{Hom}^i_{D_c(B)}(f^*(a), b) = \sum (-1)^i \dim \text{Hom}^i_{D_c(A)}(a, f_*(b)).$$

While $f_*(b)$ is not necessarily compact, it is a (homotopy) colimit of compact objects $c_i \in D_c(A)$ in the sense of [17, Tag 090Z]. As $a$ is compact, $\text{Hom}_{D_c(A)}(a, -)$ commutes with homotopy colimits. Thus the above is equal to

$$\sum (-1)^i \dim \text{colim} \text{Hom}^i_{D_c(A)}(a, c_i).$$

Computing the Euler characteristic is compatible with taking direct sums. Thus for $a \in \ker \chi$ this expression vanishes, and $f^*(a)$ is again in $\ker \chi$ as required.

The second statement follows directly from the adjunction

$$\text{Hom}_{D_c(A)}(a, f_*(b)) = \text{Hom}_{D_c(B)}(f^*(a), b).$$

□

Lemma 4.6. Let $\mathcal{V}$ a dg category and let $\mathcal{I}$ be a strictly full dg subcategory of $\mathcal{V}$. Assume that the numerical Grothendieck group of $\mathcal{V}$, $\mathcal{I}$ and $\mathcal{V}/\mathcal{I}$ exist. Then:

1. $i^*(K_0(\mathcal{I})) \cap \ker(\chi_{\mathcal{V}}) = i^*(\ker(\chi_{\mathcal{I}}))$;
2. $\ker(\chi_{\mathcal{V}/\mathcal{I}}) \supseteq q^*(\ker(\chi_{\mathcal{I}}))$.

If moreover $q$ or, equivalently, $i$ preserves compactness, then

3. $q(\ker(\chi_{\mathcal{V}/\mathcal{I}})) = q^*(\ker(\chi_{\mathcal{I}})).$

Proof. (1): The containment “$\supseteq$” follows from the proof of Lemma 4.5. For “$\subseteq$” we observe that if $i^*(a) \in \ker(\chi_{\mathcal{V}})$, then for every $b \in K_0(\mathcal{I})$ we have that $\chi(i^*(a), i^*(b)) = 0$. But as $i^*$ is the inclusion of a full subcategory, the same equation holds in $K_0(\mathcal{I})$.

(2): Again, follows from the proof Lemma 4.5.

(3): Let $a \in \ker(\chi_{\mathcal{V}/\mathcal{I}})$ and let $b := q_*(a)$. Then for any $c \in D_c(\mathcal{V})$:

$$\chi(b, c) = \chi(q_*(a), c) = \chi(a, q^*(c)) = 0.$$

Hence, $b \in \ker(\chi_{\mathcal{V}})$. As $q^* \circ q_*$ is the identity of on objects of $D_c(\mathcal{V}/\mathcal{I})$, we have that $q^*(b) = q^*(q_*(a)) = a$.

□

As mentioned in the Section 11, there is an exact sequence of the ordinary Grothendieck groups [17 Proposition VIII.3.1.1]:

$$K_0(\mathcal{I}) \to K_0(\mathcal{V}) \to K_0(\mathcal{V}/\mathcal{I}) \to 0.$$

We now descend this sequence to numerical Grothendieck groups.

Theorem 4.7. Let $\mathcal{V}$ and let $\mathcal{I}$ be a strictly full dg subcategory of $\mathcal{V}$. Assume that the numerical Grothendieck group of $\mathcal{V}$, $\mathcal{I}$ and $\mathcal{V}/\mathcal{I}$ exist. Suppose moreover that $q$ or, equivalently, $i$ preserves compactness. Then there is an exact sequence

$$K_0^{\text{num}}(\mathcal{I}) \to K_0^{\text{num}}(\mathcal{V}) \to K_0^{\text{num}}(\mathcal{V}/\mathcal{I}) \to 0.$$

Proof. It follows from (4.1) that $K_0(\mathcal{V}/\mathcal{I}) = K_0(\mathcal{V})/i^*(K_0(\mathcal{I}))$. For short, denote

$$\mathcal{K}_\mathcal{V} := \ker(\chi_{\mathcal{V}})$$

and similarly for $\mathcal{I}$ and $\mathcal{V}/\mathcal{I}$. Then by Lemma 4.5 (1) we have

$$K_0^{\text{num}}(\mathcal{V})/i^*(K_0^{\text{num}}(\mathcal{I})) = (K_0(\mathcal{V})/\mathcal{K}_\mathcal{V})/(i^*(K_0(\mathcal{I}))/\mathcal{K}_\mathcal{I}) = (K_0(\mathcal{V})/\mathcal{K}_\mathcal{V})/(i^*(K_0(\mathcal{I}))/i^*(\mathcal{K}_\mathcal{I})) \simeq (K_0(\mathcal{V})/\mathcal{K}_\mathcal{V})/(i^*(K_0(\mathcal{I}))/i^*(K_0(\mathcal{I})) \cap \mathcal{K}_\mathcal{V}).$$

As

$$i^*(K_0(\mathcal{I}))/i^*(K_0(\mathcal{I})) \cap \mathcal{K}_\mathcal{V} \simeq (i^*(K_0(\mathcal{I}))) \cdot \mathcal{K}_\mathcal{V}/\mathcal{K}_\mathcal{V},$$
the above quotient is the same as
\[ K_0(V)/(i^*(K_0(I)) \cdot K_V). \]
Using similarly the identity
\[ (i^*(K_0(I)) \cdot K_V)/i^*(K_0(I)) \simeq K_V/(i^*(K_0(I)) \cap K_V) \]
we obtain that
\[ K_0(V)/(i^*(K_0(I)) \cdot K_V) \simeq (K_0(V)/i^*(K_0(I)))/(K_V/i^*(K_0(I)) \cap K_V) \]
\[ = (K_0(V)/i^*(K_0(I)))/(q^*(K_V)) \]
\[ = (K_0(V)/i^*(K_0(I)))/K_V/I, \]
where at the second equality we used the definition of \( q^* \), and at the last equality we used Lemma \ref{lem:1}. Noting that the last line is \( K_0\text{num}(V/I) \), we deduce the statement.

\begin{proof}
Let \( \mathcal{V} \) and let \( \mathcal{I} \) be a strictly full dg subcategory of \( \mathcal{V} \). Assume that the numerical Grothendieck group of \( \mathcal{V}, \mathcal{I} \) and \( \mathcal{V}/\mathcal{I} \) exist. Suppose moreover that \( K_0(V/I) \) has no torsion. Then there is an exact sequence
\[ K_0\text{num}(\mathcal{I}) \to K_0\text{num}(\mathcal{V}) \to K_0\text{num}(V/I) \to 0. \]

This means that \( q^* \) maps \((q^*)^{-1}(A)\) to \( A \) bijectively. As the quotient functor \( q : \mathcal{V} \to \mathcal{V}/\mathcal{I} \) is the identity on objects, the same is true for \( q^* \). When \( A \) is of infinite order, the above considerations mean that \( q^* \) does not introduce any new relation for the elements representing the classes in \((q^*)^{-1}(A)\). Such new relations could occur only from the new morphisms introduced when quotienting. Recall that morphisms in \( D_\ast(V/I) \) are roofs \( b \leftarrow c \to d \) such that \( \text{Cone}(c \to b) \in D_\ast(I) \), but these morphisms are only considered up to an equivalence relation. Because there are no new relations, we must have that there are no new morphisms in the quotient. That is, all the new roofs are killed by the equivalence relation when \( b \in (q^*)^{-1}(A) \) or \( c \in (q^*)^{-1}(A) \). As a consequence,
\[ \text{Hom}_{D_\ast(V/I)}(b,c) = \text{Hom}_{D_\ast(V/I)}(q^*b,q^*c) \]
for any \( b \in (q^*)^{-1}(A) \) and \( c \in K_0(V) \). Therefore, if \( a \in \text{Ker}(\chi_{\mathcal{V}/\mathcal{I}}) \), then \((q^*)^{-1}(a) \in \text{Ker}(\chi_{\mathcal{V}})\)
because
\[ \chi((q^*)^{-1}(a),c) = \chi(a,q^*c) = 0 \]
for every \( c \in K_0(V) \). In particular, if \( K_0(V/I) \) has no torsion, then the conclusion of Lemma \ref{lem:1} \((3)\) holds, even without the assumption that \( q \) or \( i \) preserve compactness. The statement then follows as in Theorem \ref{thm:1}.
\end{proof}
