Abstract

We consider general reaction diffusion systems posed on rectangular lattices in two or more spatial dimensions. We show that travelling wave solutions to such systems that propagate in rational directions are nonlinearly stable under small perturbations. We employ recently developed techniques involving point-wise Green’s functions estimates for functional differential equations of mixed type (MFDEs), allowing our results to be applied even in situations where comparison principles are not available.

AMS 2010 Subject Classification: 34K31, 37L15.

Key words: travelling waves, multi dimensional lattice differential equations, Green’s functions, nonlinear stability, Fourier synthesis.

1 Introduction

A classical line of inquiry in applied mathematics concerns the mechanisms by which energy or activity is transported across a spatial domain. In this paper we study the dynamics in higher-dimensional spatially discrete models such as the Nagumo lattice differential equation (LDE)

\[ \dot{u}_{ij} = u_{i+1,j} + u_{i-1,j} + u_{i,j+1} + u_{i,j-1} - 4u_{ij} + g(u_{ij}), \quad (i,j) \in \mathbb{Z}^2, \]

with prototypical cubic nonlinearity \( g(u) = u(u-1)(\rho-u) \) for some \( \rho \in (0,1) \). We are interested in initial data that are close to a planar travelling wave solution

\[ u_{ij}(t) = \Phi(i\sigma_1 + j\sigma_2 + ct); \quad \Phi(-\infty) = 0, \quad \Phi(\infty) = 1. \]

*Corresponding author.
The Nagumo equation is a phenomenological model in which two stable equilibria compete for dominance in a spatial domain. In modelling contexts one often thinks of these equilibria as representing material phases or chemical or biological species. The LDE (1.1) occurs both as a model in its own right as well as a standard semi-discretization of the Nagumo PDE. Planar travelling waves (1.2) can be thought of as a mechanism of transport in which the fitter species or more energetically favourable phase invades the spatial domain, albeit for very specialized initial data. Establishing the stability of these waves, as we do here in this paper, shows that this transport mechanism is available for an open set of initial conditions in phase space.

We note that much of the prior work on stability of travelling waves in (one-dimensional) lattice reaction-diffusion equations relies heavily on comparison principles. Indeed, one can often leverage the monotonicity inherent in the problem by using Lyapunov functions or sub and super-solutions that sandwich the travelling wave; see e.g. [11, 33]. It is only recently that existence and stability results have become available for LDEs that do not admit a comparison principle [3, 20, 21]. In order to incorporate such LDEs into our analysis, we avoid the use of comparison principles in our stability results. Indeed, in the bulk of the paper we study a general class of models that includes systems of LDEs such as the discrete Fitzhugh-Nagumo equation, possibly with nonlinear and non-symmetric coupling. For concreteness however, we focus exclusively on the Nagumo equation for the remainder of this introduction, but restrict our technical discussion to spectral analysis.

Existence of Planar Fronts

To motivate (1.1) and discuss the mathematical difficulties which arise in its study, we recall the classical Nagumo PDE

\[ u_t = u_{xx} + u_{yy} + g(u) \]  

in two space dimensions. This PDE features a thresholding nonlinearity that promotes high frequencies and has to compete with the diffusion operator, which by contrast attenuates high frequencies. The resolution of this competition is the formation of travelling waves, i.e. solutions of the form

\[ u(t, x, y) = \Phi(x\sigma_1 + y\sigma_2 + ct); \quad \Phi(-\infty) = 0, \quad \Phi(\infty) = 1 \]  

which propagate with speed \(-c\) in the direction \(\sigma = (\sigma_1, \sigma_2)\) with a fixed monotone wave profile \(\Phi\). The existence of such waves can be established via phase-plane analysis, since the wave profile necessarily satisfies the planar ODE

\[ c\Phi' = \Phi'' + g(\Phi) \]  

in which we have assumed the normalization \(\sigma_1^2 + \sigma_2^2 = 1\).

We remark that in moving from the continuum to the lattice, the first main difference already appears when formulating the analogue of the travelling wave ODE (1.5). Indeed, the wave profile \(\Phi : \mathbb{R} \to \mathbb{R}\) featuring in (1.1)-(1.2) necessarily satisfies the system

\[ c\Phi'(\xi) = \Phi(\xi + \sigma_1) + \Phi(\xi - \sigma_1) + \Phi(\xi + \sigma_2) + \Phi(\xi - \sigma_2) - 4\Phi(\xi) + g(\Phi(\xi)); \quad \Phi(-\infty) = 0, \quad \Phi(\infty) = 1. \]  

Inspection of this system immediately raises two important considerations that must be addressed.

The first issue is that due to the shifted arguments, the system (1.6) is a mixed-type functional differential equation (MFDE). The theory for MFDEs is both more subtle and less well known than the theory for ODEs. Indeed, the equation (1.6) is not well-posed when regarded as an evolution equation on its natural state space \(C^0([-\sigma_{max}, \sigma_{max}], \mathbb{R})\), with \(\sigma_{max} = \max\{\sigma_1, | \sigma_2|\}\). Nevertheless, the theory for MFDEs is sufficiently mature [15, 25, 28, 31] for our purposes in this paper. For example, it is known that for each bistable \(g\) and for each \(\sigma \in \mathbb{R}^2\) there is a unique \(c\) for which (1.6) admits a monotone solution [20]. We emphasize that we do not regard the current paper as making any significant contribution towards handling MFDEs.
The second issue is that the direction of propagation $\sigma$ features prominently in (1.6), in contrast to the ODE (1.5) which is completely isotropic. In fact, this $\sigma$ dependence can be quite rough, particularly for choices of $g$ at which the two spatially constant equilibria are nearly but not exactly energetically equivalent. For such choices of $g$ the waves move slowly enough to feel the lattice discreteness as a kind of friction which further slows down the fronts, sometimes to the point of pinning them [7, 9, 15]. Moreover, both numerical and analytical work [10, 19, 23, 30] points to this additional friction being felt anisotropically, more strongly in directions such as $\sigma = (1, 0)$ and $\sigma = (1, 1)$ for which there is stronger resonance with the lattice and weakening rapidly as the resonance weakens. We regard the main contribution of this work as the extension of techniques in nonlinear stability theory to handle the peculiarities that arise in anisotropic systems.

**Stability of Travelling Fronts**

A natural question, and a chief motivator of the present study, regards the extent to which the slowing of planar fronts facing lattice directions governs the evolution of initial data which are not themselves exact travelling waves. Preliminary numerical experiments show compactly supported initial data expanding to occupy a square whose sides are aligned with the lattice directions and which propagate outwards at the (slow) speed of the planar fronts. This suggests that the anisotropy in the wave speeds of planar fronts governs the dynamics for a large set of initial data. Indeed, one may conjecture that fronts facing the lattice directions $(1, 0)$ and $(0, 1)$ play a distinguished role in governing the dynamics of a large class of initial data.

In this study we take a small step towards understanding this behaviour by establishing the multidimensional stability of planar fronts moving through the lattice $\mathbb{Z}^2$. In particular, we show that the wave speeds of the planar fronts govern the dynamics of initial data which are themselves close to planar fronts. Furthermore, our results suggest that the waves facing directions in strongest resonance with the lattice, i.e. $\sigma = (1, 0)$ or $(0, 1)$, are more stable in the following sense. Although we obtain the same slow $t^{-1/4}$ rate for the relaxation of nearly linear interfaces to linear interfaces regardless of the direction that the wave is facing, we do obtain the relatively fast $t^{-3/2}$ rate for the rest of the perturbation to fronts facing a lattice direction as compared to the relatively slow $t^{-3/4}$ that we are able to obtain for perturbations to fronts facing an oblique direction.

These observations seem to support the conjecture mentioned above. Of course, much work remains to be done and a rigorous examination of initial data that is far from a planar front is beyond the scope of this study. Such an analysis may nevertheless be regarded as a natural next step, especially in view of the fact that non-planar travelling wave solutions to PDEs have been actively investigated of late; see e.g. [17, 34].

**One-Dimensional Stability** In order to illustrate the extra complications that the anisotropy of (1.1) imposes on our nonlinear stability analysis, we start by discussing the stability of waves in one spatial dimension. The linearization of the one-dimensional version of the PDE (1.3) about its travelling wave has a simple eigenvalue at zero coming from the translational symmetry in the problem. The remainder of the spectrum is contained away from the imaginary axis in the left half-plane. That the only neutral mode arises from translation suggests the Ansatz $u(t, x) = \Phi(x + ct + \theta(t)) + v(x, t)$. The degree of freedom generated by allowing $\theta$ to vary can be used to demand that the rapidly decaying part of the perturbation $v$ is orthogonal to the (adjoint) neutral mode, implying that the linear part of the evolution for $v$ generates an exponentially stable semigroup. One can then set up and close a bootstrapping argument with $v$ decaying exponentially fast and $\theta$ remaining small.

We remark that the argument sketched above can be transferred from the one-dimensional continuum $\mathbb{R}$ to the one-dimensional lattice $\mathbb{Z}$. The chief hurdle to be overcome is that unlike in the continuum, on the lattice travelling waves are no longer equilibria in a moving frame but rather periodic modulo the shift. This observation is not new; techniques to overcome it have been developed, for example in [3, 13, 16]. Here we proceed along the lines of the program pioneered by
Benzoni-Gavage and coworkers [8] in which Green’s functions for linear LDEs are constructed by ‘filling in’ the space between lattice points, restoring the relative equilibrium point of view.

**Two-Dimensional Stability** In moving from one spatial dimension to two, an additional mathematical difficulty is that the interface is no longer compact. Instead of occupying a point or interval, it now occupies a line or strip. One must now be concerned not only with rigid translations of the front but with long wave deformations of the interface which decay slowly at the linear level. The slow decay of these long wave deformations manifests as a curve of essential spectrum which touches the origin. The presence of essential spectrum is a complicating factor in the nonlinear stability analysis of travelling waves because the semigroups associated with the linear part of the evolution now exhibit only algebraic decay and thus a bootstrapping argument is no longer guaranteed to close if (even bounded) quadratic nonlinear terms are present. Nonlinear stability in the presence of essential spectrum which touches the imaginary axis is presently an active area of research; see e.g. [5].

Essential spectrum is also present in (1.3), but several authors have managed to either skillfully manage this complication [26] or avoid it altogether [27, 35]. Nevertheless, in the current paper we now give a brief description of how the proof of stability in [26] can be adapted to the case where the front faces a lattice direction \( \sigma = (1, 0) \) and how this proof must be extended to cope with the anisotropy of the lattice. To better see this, we need to reconsider this hurdle and develop techniques to deal with the essential spectrum. The chief difficulty in our setting is that although the spectral curves are no worse than in the continuum case, the spectral projections are complicated by the anisotropy of the lattice when the front faces an oblique direction.

**Lattice Directions** In the case when the wave is facing the lattice direction \( \sigma = (1, 0) \), we use the Ansatz

\[
u_{ij}(t) = \Phi(i + ct + \theta_j(t)) + v_{ij}(t).
\]

(1.7)

Here the phase of the wave is allowed to vary in the transverse direction, meaning the direction perpendicular to the motion of the wave and parallel to the interface which separates regions dominated by the respective equilibria. After substituting such an Ansatz into the evolution (1.1), one obtains

\[
\dot{v}_{ij} = [L_{ct}v]_{ij} + \Phi'(\xi)(\theta_{j+1} + \theta_{j-1} - 2\theta_j) - \hat{\theta}_j\Phi'(\xi + \theta_j) + N_{ij}(v, \theta)
\]

(1.8)

with \( \xi = i + ct \), together with the identity

\[
[L_{ct}v]_{ij} = v_{i+1,j} + v_{i-1,j} + v_{i,j+1} + v_{i,j-1} - 4v_{ij} + g'(\Phi(i + ct))v_{ij}
\]

(1.9)

and the estimate

\[
N_{ij}(v, \theta) = O((\theta_{j+1} - \theta_j)^2 + (\theta_{j-1} - \theta_j)^2) + O(\theta_j(\theta_{j+1} + \theta_{j-1} - 2\theta_j)) + O(\theta_j v_{ij}) + O(v_{ij}^2).
\]

(1.10)

Our choice of notation emphasizes the fact that the operator \( L_{ct} \) is non-autonomous. As a consequence, it is not immediately clear how to leverage information about the spectrum of \( L_{ct} \) to obtain decay rates on the semiflow it generates. The key is to notice that the operator \( L_{ct} \) is constant-coefficient with respect to \( j \). Performing a Fourier transform in this transverse direction decouples modes with different frequencies \( \omega \) and reduces (1.9) to

\[
[L_{\omega,ct}\hat{v}(\omega)]_i = \hat{v}_{i+1}(\omega) + \hat{v}_{i-1}(\omega) + e^{i\omega}\hat{v}_i(\omega) + e^{-i\omega}\hat{v}_i(\omega) - 4\hat{v}_i(\omega) + g'(\Phi(i + ct))\hat{v}_i(\omega).
\]

(1.11)

The work of [4, 8] essentially says that the spectrum of \( L_{\omega} := -c\partial + L_{\omega,0} \), regarded as an autonomous operator from \( W^{1,\infty}(\mathbb{R}, \mathbb{R}) \to L^\infty(\mathbb{R}, \mathbb{R}) \), governs the evolution semiflow of \( \frac{d}{dt}\hat{v}(\omega) = L_{\omega,ct}\hat{v}(\omega) \) in a
fashion similar to the usual spectral mapping theorem. To obtain information regarding the operator \( L_\omega \), it suffices to drop the hats in (1.11) and write

\[
[\mathcal{L}_\omega v](\xi) = -cv'(\xi) + v(\xi + 1) + v(\xi - 1) - 2(2 - \cos \omega)v(\xi) + g'(\Phi(\xi))v(\xi). \tag{1.12}
\]

At this point, one notes that \( L_0 \) is the linearization of the one-dimensional problem about \( \Phi \) which has received ample attention from investigators. In particular, it is known that \( L_0 \) is Fredholm with index 0, kernel spanned by \( \Phi' \) and range orthogonal to an adjoint eigenfunction \( \psi \), which can be normalized to \( \langle \Phi', \psi \rangle = 1 \) \cite{28, 29}. Moreover, \( L_0 \) has no spectrum in the closed right half plane other than its simple eigenvalue at zero \cite{13, 30}. Furthermore, since \( L_\omega \) depends upon \( \omega \) only by a spectral shift, the spectral projection onto the principal eigenvector is \( \omega \)-independent. This point is absolutely crucial.

Indeed, by demanding

\[
\sum_i v_{ij}(t)\psi(i + ct) \equiv 0 \tag{1.13}
\]

uniformly in \( j \), we are essentially taking the equivalent of a spectral projection associated to the non-autonomous operator \( L_d \) onto a region \( \{ \text{Re } \lambda < -\beta \} \subset \mathbb{C} \). This implies that \( L_d \) generates an exponentially stable semiflow on \( \{ v \mid \sum_i v_{ij}\psi(i + ct) \equiv 0 \} \). Under this restriction, we will see in \S 5 that solutions to (1.8) must satisfy the fixed point problem

\[
\begin{pmatrix}
  v(t) \\
  \theta(t)
\end{pmatrix} =
\begin{pmatrix}
  \mathcal{G}_{vv}(t, 0) & \mathcal{G}_{v\theta}(t, 0) \\
  \mathcal{G}_{\theta v}(t, 0) & \mathcal{G}_{\theta\theta}(t, 0)
\end{pmatrix}
\begin{pmatrix}
  v(0) \\
  \theta(0)
\end{pmatrix}
+ \int_0^t \begin{pmatrix}
  \mathcal{G}_{vv}(t, t_0) & \mathcal{G}_{v\theta}(t, t_0) \\
  \mathcal{G}_{\theta v}(t, t_0) & \mathcal{G}_{\theta\theta}(t, t_0)
\end{pmatrix}
\begin{pmatrix}
  \mathcal{N}_v(t_0; v(t_0), \theta(t_0)) \\
  \mathcal{N}_\theta(t_0; v(t_0), \theta(t_0))
\end{pmatrix} dt_0. \tag{1.14}
\]

In view of discussion above, we expect to have the exponential bounds \( \mathcal{G}_{v*}(t, t_0) = O(e^{-\beta(t-t_0)}) \), with \( * = v, \theta \). In addition, we expect \( \mathcal{G}_{\theta\theta}(t, t_0) \) to behave similarly to a heat kernel, on account of the expansion

\[
\dot{\theta}_j = \theta_{j+1} + \theta_{j-1} - 2\theta_j + O(\theta) + O(\theta^2) \tag{1.15}
\]

one obtains after imposing (1.13) upon (1.8). The nonlinear terms can be roughly\footnote{We are deliberately suppressing all mention of the precise sequence spaces we are referring to.} bounded as

\[
\mathcal{N}_v(t; v, \theta) = O(v^2) + O(\theta v) + O((\theta^\infty)^2) + O(\theta\theta^\infty), \tag{1.16}
\]

again with \( * = v, \theta \). Here we have \( \theta^\infty_j = (\theta_{j+1} - \theta_j, \theta_{j-1} - \theta_j) \) and \( \theta^{\infty}_j = \theta_{j+1} + \theta_{j-1} - 2\theta_j \), while multiplication of sequences should be performed pointwise and componentwise. In view of the integral inequality

\[
\int_0^t e^{-\alpha t}(1 + t_0)^{-\beta} dt_0 \leq C(1 + t)^{\beta}, \tag{1.17}
\]

we expect that \( v \) will decay at the slowest algebraic rate appearing among the terms \( \mathcal{N}_v \) and \( \mathcal{N}_\theta \). Using the heuristic that \( \theta \) decays like a one-dimensional heat kernel, which means its \( k \)th difference decays like \( t^{-\frac{k+1}{2}} \), we see that the slowest decay in \( \mathcal{N}_\theta \) comes from the terms \( (\theta^\infty)^2 \) and \( \theta\theta^\infty \), which behave as \( t^{-3/2} \).

Assuming now that indeed \( v \sim t^{-3/2} \), one can easily show that \( \theta \sim t^{-1/4} \) by substituting \( \alpha = 1/4 \) and \( \beta = 3/2 \) into the integral identity

\[
\int_0^t (1 + t - t_0)^{-\alpha}(1 + t_0)^{-\beta} dt_0 \leq C(1 + t)^{-\min\{\alpha + \beta - 1, \alpha, \beta\}}; \text{ when } \alpha, \beta \neq 1, \tag{1.18}
\]

which can be found in \cite{12} Lem. 3.2.
This rough sketch of the $\sigma = (1, 0)$ case follows [20] very closely and matches exactly the results obtained there in the case of two dimensions. In fact, in this special case the LDE stability analysis is easier than the PDE stability analysis simply because all of the operators are bounded and higher-order Sobolev norms are not needed. We remark that this analysis is also reminiscent of the work in [2] in which fronts facing the horizontal direction $\sigma = (1, 0, \ldots, 0)$ are shown to be stable in $\mathbb{R}^n$ with $n \geq 4$ for the nonlocal equation $u_t = J \ast u + g(u)$ with $J$ appropriately elliptic.

**Oblique Directions** The chief difficulty in our work arises when we consider waves that are not facing the lattice directions. In order to gain some insight, let us consider a wave facing a general direction $(\sigma_1, \sigma_2) \in \mathbb{Z}^2$, with $\sigma_1^2 \neq \sigma_2^2$ and $\sigma_1\sigma_2 \neq 0$. We seek an Ansatz which decomposes the general perturbation into a slowly decaying perturbation associated with deformations of the interface and a rapidly decaying perturbation which accounts for everything else. That is, we write

$$u_{ij}(t) = \Phi(n + ct + \theta_i(t)) + v_{nl}(t); \quad n = i\sigma_1 + j\sigma_2, \quad l = j\sigma_1 - i\sigma_2. \quad (1.19)$$

Upon substituting this Ansatz into the evolution (1.1) and using the wave profile equation (1.6), we obtain

$$\dot{v}_{nl} = [L_{ct}v]_{nl} + [M_{ct}\theta]_{nl} + N_{nl}(v, \theta) + \dot{\theta}_l\Phi'(n + ct + \theta_l), \quad (1.20)$$

where

$$[L_{ct}v]_{nl} = v_{n+\sigma_1,i+\sigma_2} + v_{n+\sigma_2,i-\sigma_1} + v_{n-\sigma_1,i-\sigma_2} + v_{n-\sigma_2,i+\sigma_1} - 4v_{nl} + g'(\Phi(n + ct))v_{nl} \quad (1.21)$$

and

$$[M_{ct}\theta]_{nl} = \Phi'(n + \sigma_1 + ct)(\theta_{i+\sigma_2} - \theta_i) + \Phi'(n + \sigma_2 + ct)(\theta_{i-\sigma_1} - \theta_i) + \Phi'(n - \sigma_1 + ct)(\theta_{i-\sigma_2} - \theta_i) + \Phi'(n - \sigma_2 + ct)(\theta_{i+\sigma_1} - \theta_i), \quad (1.22)$$

as well as

$$N_{nl}(v, \theta) = \sum_{k=1}^{2} O((\theta_{i+k\sigma_2} - \theta_i)^2 + (\theta_{i-k\sigma_1} - \theta_i)^2) + \sum_{k=1}^{2} O(\theta_i(\theta_{i+k\sigma_2} - \theta_i)) + \sum_{k=1}^{2} O(\theta_i(\theta_{i-k\sigma_1} - \theta_i)) + O(\theta_{i}v_{nl}). \quad (1.23)$$

The anisotropy of the lattice manifests itself in several places. Firstly, the term $M\theta$ is linear in the first differences of $\theta$, rather than the second differences. In particular, we expect the nonlinear estimates

$$N_{\theta}(t; v, \theta) = O(v^2) + O(v\theta) + O((\theta^o)^2) + O(\theta\theta^o), \quad (1.24)$$

now with

$$\theta^o_i = (\theta_{i+\sigma_2} - \theta_i, \theta_{i-\sigma_1} - \theta_i, \theta_{i-\sigma_2} - \theta_i, \theta_{i+\sigma_1} - \theta_i). \quad (1.25)$$

The term $\theta\theta^o$ is particularly dangerous, since we can expect it to behave as $t^{-1}$, which puts us in the $\beta = 1$ case for which (1.18) fails to hold.

This particular difficulty is often encountered in the study of stability analysis of travelling waves in PDE with conservation law structure such as viscous shocks, e.g. [20]. We make use of the simple, yet crucial, identity

$$\theta_i(\theta_{i+1} - \theta_i) = \frac{1}{2}[\theta_{i+1}^2 - \theta_i^2 - (\theta_{i+1} - \theta_i)^2], \quad (1.26)$$

which can be regarded as a discrete form of $uw = \left(\frac{1}{2}u^2\right)_x$. The square of the first difference decays like $t^{-1/2}$ and hence is safe. The difference of the squares though only decays like $t^{-1}$. However, we can sum by parts, transferring the difference to the heat kernel and in so doing move from the bad estimate

$$\int_0^t (1 + t - s)^{-1/4}(1 + s)^{-1}ds \sim \log(1 + t)(1 + t)^{-1/4} \quad (1.27)$$
to the good estimate

$$\int_0^t (1 + t - s)^{-3/4}(1 + s)^{-1/2} ds \sim (1 + t)^{-1/4}.$$  

(1.28)

In particular, we must carefully keep track of the nonlinear terms of order $O(\theta \psi^\circ)$ to make sure that they have the correct form.

Before we can proceed further, we need to decide on a normalization condition to use for the phases $\theta$. The linear operators $L_\omega$ are now given by

$$[L_\omega v]_n = -cv_n' + e^{i\omega \sigma_2}v_{n+\sigma_1} + e^{-i\omega \sigma_1}v_{n+\sigma_2} + e^{-i\omega \sigma_2}v_{n-\sigma_1} + e^{i\omega \sigma_1}v_{n-\sigma_2} - 4v_n$$

$$+ g'(\Phi(n + ct))v_n.$$  

(1.29)

In particular, the dependence on the frequency $\omega$ is now non-trivial. It is true that $L_0$ still has a simple eigenvalue at zero with the rest of the spectrum in the left half-plane and thus regular perturbation yields a curve of eigenvalues $\lambda_n$ and eigenvectors $\phi_n$. However, because the leading eigenvalues $\phi_n$ depend upon $\omega$, the natural orthogonality condition now lives in the Fourier domain. Indeed, it is natural to require that for each frequency $\omega$, the spectral projection onto $\phi_n$ of the Fourier coefficient $\hat{v}(\omega)$ must vanish. On the range of such a projection, one would expect the operator $L_{ct}$ to generate an exponentially stable semiflow.

However, we feel that the frequency mixing inherent in such a projection will lead to prohibitively complicated expressions for the nonlinearities that will most likely prevent us from verifying the conservation-law structure of the $O(\theta \psi^\circ)$ terms. This would thwart any attempts to circumvent the $\beta = 1$ problem in (1.18) through the use of (1.26). For this reason, we continue to use the frequency independent normalization

$$\sum_n v_n(\psi(n + ct)) \equiv 0$$  

(1.30)

that worked so well in the $\sigma = (1, 0)$ case. The price that needs to be paid is that the semiflow $G_{\psi \theta}(t, t_0)$ now decays algebraically at the rather slow rate of $O((1 + t - t_0)^{-3/4})$. The frequency dependence of the eigenfunctions $\phi_n$ is directly to blame for this.

At first glance, this means that the $O(\theta \psi)$ term in (1.24) behaves as $t^{-1}$, which of course is problematic. By carefully inspecting the part of $G_{\psi \theta}$ that decays at the slowest rate, we are able to show that the troublesome portion of $\psi$ is directly proportional to $\theta^\circ$. Together with a detailed analysis of the $O(\theta \psi)$ terms in the nonlinearities, this allows the use of (1.26) to prevent the logarithm from appearing in (1.27).

**Overview**

In the following sections we flesh out in great detail the sketch presented above. In §2 we state our hypotheses and main theorems. Our theorems are of the form “spectral stability implies nonlinear stability.” Our hypotheses relate largely to the existence of a travelling wave and spectral assumptions on the analog of $L_0$ and $L_\omega$. Section 3 is devoted to the development of coordinate systems, both the $(n, l)$ coordinates for the lattice and the $(v, \theta)$ coordinates for $u$ as well as to the derivation of a system of evolution equations in these coordinates and the estimation of the nonlinear terms. Section 4 is devoted to linear analysis, namely pointwise estimates on the Green’s functions associated with the $(v, \theta)$ evolution at the linear level. Section 5 is devoted to nonlinear stability, showing that so long as all of the terms on the right hand side decay as they ought for $t \in [0, T]$, then they actually decay as they ought for $t \in [0, \infty)$. Finally in §6 we show that our theorem is not vacuous. More concretely, we verify our abstract hypotheses for the Nagumo equation (1.1). All of the hypotheses with analogs in the continuum case [20] we can verify analytically. However we need to make an additional hypothesis (HS1)$_\omega$ to control terms which arise due to the anisotropy of the lattice. With the exception of the $\sigma = (1, 0)$ (resp. $\sigma = (1, 1)$) case in which these terms are absent (resp. benign), we cannot analytically verify this hypothesis and instead use numerics. We conclude in §7
by discussing the decisions we made that limit the scope of our work and suggesting potential areas for further research.

2 Main Results

Consider the nearest-neighbour lattice differential equation

\[ \dot{u}_{ij}(t) = f(u_{i+1,j}(t), u_{i,j+1}(t), u_{i-1,j}(t), u_{i,j-1}(t), u_{ij}(t)), \]  

(2.1)

for which \( u_{ij}(t) \in \mathbb{R}^d \) for all \((i, j) \in \mathbb{Z}^2\). For convenience, we introduce the symbol \( \pi^+_{ij} : \ell^\infty(\mathbb{Z}^2; \mathbb{R}^d) \to (\mathbb{R}^d)^5 \) for any pair \((i, j) \in \mathbb{Z}^2\), which acts as

\[ \pi^+_{ij} u = (u_{i+1,j}, u_{i,j+1}, u_{i-1,j}, u_{i,j-1}, u_{ij}) \in (\mathbb{R}^d)^5. \]

(2.2)

In particular, these operators produce a vector of neighbouring grid points that are arranged according to the "+"-shaped stencil. The system (2.1) can now be written in the condensed form

\[ \dot{u}_{ij}(t) = f(\pi^+_{ij} u(t)). \]

(2.3)

The conditions we need on the nonlinearity \( f \) are summarized in the following assumption.

(Hf) The nonlinearity \( f : (\mathbb{R}^d)^5 \to \mathbb{R}^d \) is \( C^2 \)-smooth and there exist two points \( u_\pm \in \mathbb{R}^d \) with

\[ f(u_\pm, u_\pm, u_\pm, u_\pm, u_\pm) = 0. \]

(2.4)

We emphasize that \( u_- \) and \( u_+ \) do not need to be equal. Let us now pick an arbitrary pair \((\sigma_1, \sigma_2) \in \mathbb{Z}^2\) with \( \gcd(\sigma_1, \sigma_2) = 1 \). Our next assumption states that (2.1) admits a wave solution that travels in the direction \((\sigma_1, \sigma_2)\) through the lattice.

(HΦ) There exists a wave speed \( c \neq 0 \) and a wave profile \( \Phi \in C^3(\mathbb{R}, \mathbb{R}^d) \) that satisfies the limits

\[ \lim_{\xi \to \pm \infty} \Phi(\xi) = u_\pm \]

(2.5)

and yields a solution to (2.1) upon writing

\[ u_{ij}(t) = \Phi(i\sigma_1 + j\sigma_2 + ct). \]

(2.6)

We note that the pair \((c, \Phi)\) solves the functional differential equation of mixed type (MFDE)

\[ c\Phi'(\xi) = f(\Phi(\xi + \sigma_1), \Phi(\xi + \sigma_2), \Phi(\xi - \sigma_1), \Phi(\xi - \sigma_2), \Phi(\xi)). \]

(2.7)

In particular, the \( C^3 \)-continuity mentioned in (HΦ) is automatic upon assuming that \( \Phi \) is merely continuous. For conciseness, we rewrite (2.7) in the form

\[ c\Phi'(\xi) = f([\tau \Phi](\xi)), \]

(2.8)

in which the operator \( \tau : C(\mathbb{R}, \mathbb{R}^d) \to C(\mathbb{R}, (\mathbb{R}^d)^5) \) acts as

\[ [\tau p](\xi) = (p(\xi + \sigma_1), p(\xi + \sigma_2), p(\xi - \sigma_1), p(\xi - \sigma_2), p(\xi)) \in (\mathbb{R}^d)^5. \]

(2.9)
A standard approach towards establishing the stability of the wave \((c, \Phi)\) under the nonlinear dynamics of the LDE (2.1) is to consider the linear variational problem
\[
\dot{v}_n(t) = Df([\tau \Phi](n + ct)) \left( e^{i\sigma_2 \omega} v_{n+\sigma_1}(t), e^{-i\sigma_1 \omega} v_{n+\sigma_2}(t), e^{-i\sigma_2 \omega} v_{n-\sigma_1}(t), e^{i\sigma_1 \omega} v_{n-\sigma_2}(t), v_n(t) \right). 
\] (2.10)
As can be seen, the linear operator on the right hand side of this system does not have constant coefficients and hence cannot be diagonalized via Fourier transform. It can however be partially diagonalized if one takes the Fourier transform in the direction that is perpendicular to the propagation of the wave, i.e., upon taking \(i\sigma_1 + j\sigma_2 + ct = \text{constant}\). As explained in §4, one arrives for each transverse spatial frequency \(\omega \in [-\pi, \pi]\) at an LDE posed on a one dimensional lattice that is parallel to the direction of propagation. This LDE is given by
\[
\dot{v}_n(t) = Df([\tau \Phi](n + ct)) \left( e^{i\sigma_2 \omega} v_{n+\sigma_1}(t), e^{-i\sigma_1 \omega} v_{n+\sigma_2}(t), e^{-i\sigma_2 \omega} v_{n-\sigma_1}(t), e^{i\sigma_1 \omega} v_{n-\sigma_2}(t), v_n(t) \right), 
\] (2.11)
in which we have \(n = i\sigma_1 + j\sigma_2\). As explained in detail in [28, §2], there is a close relationship between the Green’s function for the LDE (2.11) and the linear operators
\[
[L_\omega p](\xi) = -c p'(\xi) + Df([\tau \Phi](\xi))[\tau_\omega p](\xi),
\] (2.12)
in which the operator \(\tau_\omega : C(\mathbb{R}, \mathbb{R}^d) \to C(\mathbb{R}, (\mathbb{R}^d)^5)\) is defined by
\[
[\tau_\omega p](\xi) = (e^{i\sigma_2 \omega} p(\xi + \sigma_1), e^{-i\sigma_1 \omega} p(\xi + \sigma_2), e^{-i\sigma_2 \omega} p(\xi - \sigma_1), e^{i\sigma_1 \omega} p(\xi - \sigma_2), p(\xi)) \in (\mathbb{R}^d)^5.
\] (2.13)
Written out in the traditional form used in the landmark paper [28], we have
\[
[L_\omega p](\xi) = -c p'(\xi) + \sum_{j=1}^{5} A_{\omega,j}(\xi)p(\xi + r_j),
\] (2.14)
in which the shifts \(r_j\) and operators \(A_{\omega,j}\) are given by
\[
\begin{align*}
\begin{array}{c|c}
 r_1 & \sigma_1 \\
r_2 & \sigma_2 \\
r_3 & -\sigma_1 \\
r_4 & -\sigma_2 \\
r_5 & 0 \\
\end{array}
\end{align*}
\begin{align*}
\begin{array}{c|c}
 A_{\omega,1}(\xi) & e^{i\sigma_2 \omega} D_1 f(\Phi(\xi + \sigma_1), \Phi(\xi + \sigma_2), \Phi(\xi - \sigma_1), \Phi(\xi - \sigma_2), \Phi(\xi)) \\
A_{\omega,2}(\xi) & e^{-i\sigma_1 \omega} D_2 f(\Phi(\xi + \sigma_1), \Phi(\xi + \sigma_2), \Phi(\xi - \sigma_1), \Phi(\xi - \sigma_2), \Phi(\xi)) \\
A_{\omega,3}(\xi) & e^{-i\sigma_2 \omega} D_3 f(\Phi(\xi + \sigma_1), \Phi(\xi + \sigma_2), \Phi(\xi - \sigma_1), \Phi(\xi - \sigma_2), \Phi(\xi)) \\
A_{\omega,4}(\xi) & e^{i\sigma_1 \omega} D_4 f(\Phi(\xi + \sigma_1), \Phi(\xi + \sigma_2), \Phi(\xi - \sigma_1), \Phi(\xi - \sigma_2), \Phi(\xi)) \\
A_{\omega,5}(\xi) & D_5 f(\Phi(\xi + \sigma_1), \Phi(\xi + \sigma_2), \Phi(\xi - \sigma_1), \Phi(\xi - \sigma_2), \Phi(\xi)). \\
\end{array}
\end{align*}
\] (2.15)
The formal adjoints of these operators are written as
\[
[L_\omega^* : W^{1,\infty}(\mathbb{R}, \mathbb{C}^d) \to L^\infty(\mathbb{R}, \mathbb{C}^d), \quad \omega \in [-\pi, \pi],
\] (2.16)
and act as
\[
[L_\omega^* q](\xi) = c q'(\xi) + \sum_{j=1}^{5} A_{\omega,j}^*(\xi)q(\xi - r_j).
\] (2.17)
Indeed, the designation of formal adjoint is justified by an easy computation which shows that
\[
\int_{-\infty}^{\infty} \langle q(\xi), [L_\omega p](\xi) \rangle \, d\xi = \int_{-\infty}^{\infty} \langle [L_\omega^* q](\xi), p(\xi) \rangle \, d\xi
\] (2.18)
holds for all pairs $p,q \in W^{1,\infty}(\mathbb{R}, \mathbb{C}^d)$, where $(\cdot, \cdot)$ denotes the standard inner product on $\mathbb{C}^d$. We emphasize that for the rest of the paper we will reserve the symbol $(\cdot, \cdot)$ to denote the standard inner product on $\mathbb{C}^d$ or $\mathbb{R}^d$ with $\ell^2 (L^2)$ inner products always written out as sums (integrals).

In view of the fact that $r_j \in \mathbb{Z}$ holds for all the shifts, an easy computation shows that

$$e^{-2\pi i\ell}(\mathcal{L}_\omega - \lambda)e^{2\pi i\ell} = \mathcal{L}_\omega - 2\pi i\ell c - \lambda$$

(2.20)

for all $\lambda \in \mathbb{C}$ and $\ell \in \mathbb{Z}$, in which the exponential shift operator $e^\nu$ is defined by

$$[e^\nu v](\xi) = e^{\nu\xi} v(\xi).$$

(2.21)

In particular, for all $\omega \in [-\pi, \pi]$, the spectrum of $\mathcal{L}_\omega$ is invariant under the operation $\lambda \mapsto \lambda + 2\pi i\ell$. We now proceed to describe the precise assumptions we need to impose on the spectra of these operators.

Since $\Phi(\xi)$ approaches $u_\pm$ as $\xi \to \infty$, we can define the characteristic functions

$$\Delta_\nu^\pm(\tau) = -cz + \sum_{j=1}^5 \lim_{\xi \to \pm\infty} A_{\omega,j}(\xi)[e^{\nu\xi}]$$

(2.22)

for each $\omega \in [-\pi, \pi]$. Our first spectral assumption states that the characteristic functions associated to $\mathcal{L}_\omega - \lambda$ cannot have roots on the imaginary axis if $\text{Re} \lambda \geq 0$.

(HS)\textsubscript{ess} For all $\omega \in [-\pi, \pi]$ and $\lambda \in \mathbb{C}$ that have $\text{Re} \lambda \geq 0$, we have

$$\text{det}[\Delta_\nu^\pm(i\nu) - \lambda I] \neq 0$$

(2.23)

for all $\nu \in \mathbb{R}$.

Since (2.20) implies that we can restrict $\text{Im} \lambda$ to a compact interval, the \textit{a priori} bound on solutions $\nu \in \mathbb{R}$ to (2.23) obtained in [21] Lem. 3.1 shows that (2.23) in fact holds whenever $\text{Re} \lambda \geq -\beta$ for some $\beta > 0$. In particular, in view of [28, Thm. A], (HS)\textsubscript{ess} implies that the operators $\mathcal{L}_\omega - \lambda$ are Fredholm whenever $\text{Re} \lambda \geq -\beta$.

Notice that $\tau_0 = \tau$. It is natural to expect that the operator $\mathcal{L}_0$ encodes stability properties of the wave $(c, \Phi)$ under perturbations that are constant in the direction transverse to propagation. Indeed, our next three spectral assumptions on $\mathcal{L}_0$ are sufficient to guarantee the nonlinear stability of the wave under such perturbations [33]. These assumptions basically state that $\mathcal{L}_0$ has isolated simple point spectrum at $\lambda \in \{2\pi ic\}$ and no other spectrum in the half-plane $\text{Re} \lambda \geq -\beta$.

(HS1)\textsubscript{p} There exists $\beta > 0$ such that $\mathcal{L}_0 - \lambda$ is invertible as a map from $W^{1,\infty}(\mathbb{R}, \mathbb{C}^d)$ into $L^\infty(\mathbb{R}, \mathbb{C}^d)$ for all $\lambda \notin 2\pi ic\mathbb{Z}$ that have $\text{Re} \lambda \geq -\beta$.

(HS2)\textsubscript{p} The only nontrivial solutions $p \in W^{1,\infty}(\mathbb{R}, \mathbb{C}^d)$ of $\mathcal{L}_0p = 0$ are $p = \Phi'$ and scalar multiples thereof.

(HS3)\textsubscript{p} The equation $\mathcal{L}_0p = \Phi'$ does not admit a solution $p \in W^{1,\infty}(\mathbb{R}, \mathbb{C}^d)$.

Throughout the remainder of this paper, we will use the shorthand $\phi := \Phi'$.

As we have discussed above, the operator $\mathcal{L}_0$ is Fredholm. The continuity of the Fredholm index together with (HS1)\textsubscript{p} imply that the Fredholm index of $\mathcal{L}_0$ must be zero. Using [28, Thm. A] together with (HS2)\textsubscript{p}, one sees that the kernel of $\mathcal{L}_0$ must be one-dimensional. Another application of [28, Thm. A] now in combination with (HS3)\textsubscript{p} shows that the kernel of $\mathcal{L}_0$ is spanned by a function $\psi \in W^{1,\infty}(\mathbb{R}, \mathbb{R}^d)$ that can be uniquely fixed by the identity

$$\int_{-\infty}^\infty (\psi(\xi), \phi(\xi))d\xi = 1,$$

(2.24)
since \( \phi \) does not lie in the range of \( \mathcal{L}_0 \). In addition, both \( \phi(\xi) \) and \( \psi(\xi) \) decay exponentially as \( \xi \to \infty \). Finally, a short computation along the lines of [20] Lem 2.9 yields the useful identity

\[
\sum_{n \in \mathbb{Z}} \langle \psi(n + \vartheta), \phi(n + \vartheta) \rangle = \int_{-\infty}^{\infty} \langle \psi(\xi), \phi(\xi) \rangle d\xi = 1,
\]

which holds for every \( \vartheta \in \mathbb{R} \).

Before we proceed, we introduce for any \( \zeta \in \mathbb{R} \) the exponentially weighted spaces

\[
BC_{\zeta}^1(\mathbb{R}, \mathbb{C}^d) = \{ p \in C(\mathbb{R}, \mathbb{C}^d) \mid \sup_{\xi \in \mathbb{R}} e^{-\zeta|\xi|} |p(\xi)| < \infty \},
\]

\[
BC_{\zeta}^1(\mathbb{R}, \mathbb{C}^d) = \{ p \in C^1(\mathbb{R}, \mathbb{C}^d) \mid \sup_{\xi \in \mathbb{R}} e^{-\zeta|\xi|} \|p(\xi) + |p'(\xi)|\| < \infty \}.
\]

The following perturbation result is a direct consequence of the assumptions (HS1), (HS3). It basically states that there is a branch of simple eigenvalues \( \lambda_\omega \), for \( \mathcal{L}_\omega \) with corresponding eigenvectors \( \phi_\omega \) and adjoint eigenvectors \( \psi_\omega \). These eigenvectors decay exponentially at a rate that can be chosen to be independent of \( \omega \). In addition, with the exception of simple eigenvalues at \( \lambda_\omega + 2\pi ic\mathbb{Z} \), the spectrum of \( \mathcal{L}_\omega \) lies to the left of the line \( \text{Re} \lambda = -\beta \).

**Proposition 2.1.** Assume that \( (Hf), (H\Phi), (HS)_{\text{ess}} \) and \( (HS1)_p, (HS3)_p \) all hold. Then there exists a constant \( 0 < \delta_\omega \ll 1 \) together with triplets

\[
(\lambda_\omega, \phi_\omega, \psi_\omega) \in \mathbb{C} \times W^{1,\infty}(\mathbb{R}, \mathbb{C}^d) \times W^{1,\infty}(\mathbb{R}, \mathbb{C}^d),
\]

defined for each \( \omega \in (-\delta_\omega, \delta_\omega) \), such that the following hold true.

(i) There exists \( \beta > 0 \) such that for all \( \omega \in (-\delta_\omega, \delta_\omega) \), the operator \( \mathcal{L}(\omega) - \lambda \) is invertible as a map from \( W^{1,\infty}(\mathbb{R}, \mathbb{C}^d) \) into \( L^\infty(\mathbb{R}, \mathbb{C}^d) \), for all \( \lambda \in \mathbb{C} \) that have \( \text{Re} \lambda \geq -\beta \) and for which \( \lambda - \lambda_\omega \notin 2\pi i\mathbb{Z} \).

(ii) The only nontrivial solutions \( p \in W^{1,\infty}(\mathbb{R}, \mathbb{C}^d) \) of \( (\mathcal{L}_\omega - \lambda_\omega)p = 0 \) are \( p = \phi_\omega \) and scalar multiples thereof.

(iii) The only nontrivial solutions \( q \in W^{1,\infty}(\mathbb{R}, \mathbb{C}^d) \) of \( (\mathcal{L}_\omega^* - \lambda_\omega)q = 0 \) are \( q = \psi_\omega \) and scalar multiples thereof.

(iv) For all \( \omega \in (-\delta_\omega, \delta_\omega) \) we have

\[
\int_{-\infty}^{\infty} \langle \psi_\omega(\xi), \phi_\omega(\xi) \rangle d\xi = 1.
\]

In particular, the equation \( (\mathcal{L}_\omega - \lambda_\omega)v = \phi_\omega \) does not admit a solution \( v \in W^{1,\infty}(\mathbb{R}, \mathbb{C}^d) \).

(v) There exists \( \eta > 0 \) such that the maps

\[
\omega \mapsto \begin{cases} 
\lambda_\omega \in \mathbb{C}, \\
\phi_\omega \in BC_{-\eta}(\mathbb{R}, \mathbb{C}^d) \\
\psi_\omega \in BC_{-\eta}(\mathbb{R}, \mathbb{C}^d)
\end{cases}
\]

are all well-defined and \( C^2 \)-smooth.

(vi) We have \( \lambda_0 = 0, \phi_0 = \phi \) and \( \psi_0 = \psi \).

**Proof.** The key observation is that for sufficiently small \( \eta > 0 \), the operator \( \mathcal{L}_0 \) is also a Fredholm operator with index zero when viewed as a map from \( BC_{-\eta}^1(\mathbb{R}, \mathbb{C}^d) \) into \( BC_{-\eta}(\mathbb{R}, \mathbb{C}^d) \). This can be seen as in [4] Lem. 4.7] by observing that the operator

\[
\mathcal{L}_0 : p \mapsto \mathcal{L}_0[\cosh(\eta p)]^{-1}p(p)
\]

(2.30)
is an operator of the form covered by the theory in [28] that in addition is asymptotically hyperbolic. In particular, it is a Fredholm operator mapping $BC^1(\mathbb{R}, \mathbb{C}^d)$ into $BC_0(\mathbb{R}, \mathbb{C}^d)$ with a one-dimensional kernel spanned by the bounded function $\xi \mapsto \cosh(\eta \xi) \phi(\xi)$. In addition, the index of $L_0$ viewed as a map between these two spaces is zero, which can be concluded from the spectral flow formula in [28 Thm. C].

All the properties stated above now follow from regular perturbation. Indeed, the map $\omega \mapsto L_\omega$ is analytic and the perturbation $L_0 - L_\omega$ is bounded. More explicitly, consider the range

$$R = L_0(BC^1(\mathbb{R}, \mathbb{C}^d)) \subset BC_{-\eta}(\mathbb{R}, \mathbb{C}^d)$$

and define $F : R \times \mathbb{C} \times \mathbb{R} \rightarrow BC_{-\eta}(\mathbb{R}, \mathbb{C}^d)$ by

$$F(p, \lambda, \omega) = (L_\omega - \lambda)(\phi + p).$$

Observe that $F(0, 0, 0) = 0$ and compute the derivative

$$D_{p, \lambda}F(0, 0, 0) : (\delta \lambda, \delta p) \mapsto L_0 \delta \phi - \lambda \delta \phi,$$

which is injective as a consequence of $\phi \notin R$ and (HS2) and surjective because $BC_{-\eta}(\mathbb{R}, \mathbb{C}^d) = R \oplus \text{span}\{\phi\}$. The desired curves $\omega \mapsto (\lambda_\omega, \phi_\omega)$ are now a direct consequence of the implicit function theorem, upon writing $\phi_\omega = \phi + p_\omega$. The remaining curve $\omega \mapsto \psi_\omega$ can be constructed in a similar fashion.

The first of our two final assumptions ensures that the curve $\omega \mapsto \lambda_\omega$ touches the origin in a quadratic tangency that opens up on the left side of the imaginary axis. The second assumption guarantees that the only part of the spectrum of the operators $L_\omega$ with $\omega \in [-\pi, \pi]$ that can potentially lie in the half-plane $\text{Re} \lambda \geq -\eta$ are the simple isolated eigenvalues $\lambda_\omega + 2\pi i c \mathbb{Z}$ defined for $\omega \approx 0$.

(HS1)$_\omega$ Recalling the curves $\omega \mapsto (\lambda_\omega, \phi_\omega)$ defined in Proposition 2.1, we have the Melnikov identity

$$\int_{-\infty}^{\infty} \left( \psi(\xi), \left[ \partial_\omega L_\omega, \omega = 0 \right] \phi(\xi) \right) d\xi$$

$$+ 2 \int_{-\infty}^{\infty} \left( \psi(\xi), \left[ \left[ \partial_\omega \partial_\omega L_\omega, \omega = 0 \right], \left[ \partial_\omega \phi_\omega, \omega = 0 \right] \right] (\xi) \right) d\xi \neq 0.$$  

(HS2)$_\omega$ For all $\omega \in [-\pi, \pi] \setminus \{0\}$ and $\lambda \in \mathbb{C}$ that have $\text{Re} \lambda \geq 0$, the operator $L_\omega - \lambda$ is invertible as a map from $W^{1,2}(\mathbb{R}, \mathbb{C}^d)$ into $L^\infty(\mathbb{R}, \mathbb{C}^d)$.

**Proposition 2.2.** Consider the setting of Proposition 2.1. We have $[\partial_\omega \lambda_\omega, \omega = 0] \in i\mathbb{R}$ and $[\partial_\omega \phi_\omega, \omega = 0]$ takes values in $i\mathbb{R}^d$. In addition, if (HS1)$_\omega$ also holds, then there exists a constant $\kappa > 0$ such that

$$\text{Re} \lambda_\omega < -\kappa \omega^2$$

for all $\omega \in (-\delta_\omega, \delta_\omega)$.

**Proof.** To address the imaginary claims we Taylor expand the quantities $\lambda_\omega$, $\phi_\omega$ and $\psi_\omega$ in $\omega$ about $\omega = 0$ in the expression $(L_\omega - \lambda_\omega)\phi_\omega = 0$ to obtain

$$O(\omega^3) = L_0 \phi + \omega \left( L_0 \left[ \partial_\omega \phi_\omega, \omega = 0 \right] + \left[ \partial_\omega L_\omega, \omega = 0 \right] \right)$$

$$+ \frac{\omega^2}{2} \left( L_0 \left[ \partial_\omega^2 \phi_\omega, \omega = 0 \right] + 2 \left[ \partial_\omega L_\omega, \omega = 0 \right] \left[ \partial_\omega \phi_\omega, \omega = 0 \right] + \left[ \partial_\omega^2 L_\omega, \omega = 0 \right] \right).$$

Taking the inner product against $\psi$ and recalling that $L_0^* \psi = 0$ leaves

$$[\partial_\omega \lambda_\omega, \omega = 0] = \int_{-\infty}^{\infty} \left( \psi(\xi), [\partial_\omega L_\omega, \omega = 0] \phi(\xi) \right) d\xi.$$
Inspecting the definition of $L_\omega$ shows that $i[\partial_\omega L_\omega]_{\omega=0}$ maps real-valued functions to real-valued functions. This together with the fact that $\phi$ and $\psi$ are real-valued implies that $i[\partial_\omega \lambda_\omega]_{\omega=0}$ is real.

In order to obtain (2.35), it suffices to integrate the $O(\omega^2)$ term in (2.36) against $\psi$, yielding

\[
[\partial^2_\omega \lambda_\omega]_{\omega=0} = \int_{-\infty}^{\infty} (\psi(\xi), \left[\partial^2_\omega L_\omega\right]_{\omega=0} \phi(\xi))\, d\xi + 2\int_{-\infty}^{\infty} (\psi(\xi), \left[[\partial_\omega L_\omega - \partial_\omega \lambda_\omega]_{\omega=0} \right] \phi(\xi))\, d\xi. \tag{2.38}
\]

\[\Box\]

**Proposition 2.3.** Assume that $(Hf)$, $(H\Phi)$, $(HS)_{\text{ess}}$, $(HS1)_{\omega}$, $(HS3)_{p}$, and $(HS2)_{\omega}$ all hold and recall the constant $0 < \delta_2 \ll 1$ from Proposition 2.1. Then there exists a constant $\beta > 0$ such that for all $\omega \in \mathbb{C}$ that have $\Re \lambda \geq -\beta$ and all $\omega \in [-\pi, \pi]$ that have $|\omega| \geq \delta_2$, the operator $L_\omega - \lambda$ is invertible as a map from $W^{1,\infty}(\mathbb{R}, \mathbb{C}^d)$ into $L^{\infty}(\mathbb{R}, \mathbb{C}^d)$.

**Proof.** This follows from the continuous dependence of $L_\omega$ on $\omega$, the fact that resolvent sets are open and the identity (2.20) which shows we only have to consider spectral parameters $\lambda$ in compact sets. \[\Box\]

We are now almost ready to state our main results. First, we introduce for any $\vartheta \in \mathbb{R}$ the function $\chi(\vartheta) \in \ell^\infty(\mathbb{Z}; \mathbb{R}^d)$ defined by

\[
\chi_n(\vartheta) = -i[\partial_\omega \phi_\omega]_{\omega=0}(n+\vartheta) + i\vartheta(n+\vartheta) \sum_{\ell \in \mathbb{Z}} (\psi(\ell + \vartheta), [\partial_\omega \phi_\omega]_{\omega=0}(\ell + \vartheta)). \tag{2.39}
\]

This can be seen as the residual of the $\mathbb{R}^d$-valued function $-i[\partial_\omega \phi_\omega]_{\omega=0}$ after projecting out the part along $\phi(\cdot + \vartheta)$.

**Theorem 2.4.** Consider the LDE (2.1) and suppose that $(Hf)$, $(H\Phi)$, $(HS)_{\text{ess}}$, $(HS1)_{\omega}$, $(HS3)_{p}$ and $(HS2)_{\omega}$ are all satisfied. Pick any $\alpha < \frac{5}{4}$ and $1 \leq p \leq \infty$. Then there exist constants $\delta > 0$ and $C > 0$ such that for any $v^0 \in \ell^\infty(\mathbb{Z}; \mathbb{R}^d)$ that can be bounded by

\[
\|v^0\|_{\ell^p(\mathbb{Z}; \mathbb{R}^d)} \leq \delta, \tag{2.40}
\]

there exist $C^1$-smooth functions $\theta : [0, \infty) \to \ell^\infty(\mathbb{Z}; \mathbb{R})$ and $w : [0, \infty) \to \ell^\infty(\mathbb{Z}; \mathbb{R}^d)$ that satisfy the following properties.

(i) The function

\[
u_{ij}(t) = \Phi(i\sigma_1 + j\sigma_2 + ct + \theta_{i\sigma_2 - j\sigma_1}(t)) + \chi_{i\sigma_1 + j\sigma_2}(ct)(\theta_{i\sigma_2 - j\sigma_1 + 1}(t) - \theta_{i\sigma_2 - j\sigma_1}(t)) + w_{i\sigma_1 + j\sigma_2,i\sigma_2 - j\sigma_1}(t) \tag{2.41}
\]

satisfies (2.1) for all $t \geq 0$ with the initial condition

\[
u_{ij}(0) = \Phi(i\sigma_1 + j\sigma_2) + v^0_{i\sigma_1 + j\sigma_2,i\sigma_2 - j\sigma_1}. \tag{2.42}
\]

(ii) For all $t \geq 0$ and all $l \in \mathbb{Z}$ we have

\[
\sum_{n \in \mathbb{Z}} (\psi(n + ct), w_{n l}(t)) = 0. \tag{2.43}
\]

\[\footnote{The $\ell^p$ norm is taken with respect to the first index and the $\ell^1$ norm with respect to the second index.}\]
(iii) The function \( \theta \) satisfies the estimates
\[
\| \theta(t) \|_{L^2(Z; \mathbb{R})} \leq C(1 + t)^{-1/4} \| v^0 \|_{L^p(Z; \mathbb{R}^d)}, \\
\| \theta(t) \|_{L^\infty(Z; \mathbb{R})} \leq C(1 + t)^{-1/2} \| v^0 \|_{L^p(Z; \mathbb{R}^d)}.
\]  
(2.44)

(iv) The function \( \theta_{\text{diff}} : [0, \infty) \to L^\infty(Z; \mathbb{R}) \) defined by
\[
[\theta_{\text{diff}}](t) = \theta_{t+1}(t) - \theta_t(t)
\]
\[
\| \theta_{\text{diff}}(t) \|_{L^2(Z; \mathbb{R})} \leq C(1 + t)^{-3/4} \| v^0 \|_{L^p(Z; \mathbb{R}^d)}, \\
\| \theta_{\text{diff}}(t) \|_{L^\infty(Z; \mathbb{R})} \leq C(1 + t)^{-1} \| v^0 \|_{L^p(Z; \mathbb{R}^d)}.
\]  
(2.46)

(v) The function \( w \) satisfies the estimates
\[
\| w(t) \|_{L^p(Z; \mathbb{R}^d)} \leq C(1 + t)^{-\alpha} \| v^0 \|_{L^p(Z; \mathbb{R}^d)}, \\
\| w(t) \|_{L^\infty(Z; \mathbb{R}^d)} \leq C(1 + t)^{-5/4} \| v^0 \|_{L^p(Z; \mathbb{R}^d)}.
\]  
(2.47)

Our final two results cover situations where the wave travels in directions that are preferred by the lattice, in which case the decay rates on \( v(t) \) can be improved. Notice that we only recover the bounds obtained by Kapitula [25] when analyzing waves that travel horizontally or vertically and for which the perpendicular discrete diffusion coefficients are multiples of the identity matrix. In fact, in this case we even get slightly faster decay rates, because we can exploit the embedding \( L^1(Z; \mathbb{R}) \subset L^2(Z; \mathbb{R}) \subset L^\infty(Z; \mathbb{R}) \), which does not generalize to the function spaces \( L^q(\mathbb{R}; \mathbb{R}) \).

**Theorem 2.5.** Consider the LDE (2.1) and suppose that \((Hf), (H\Phi), (HS)_{\text{ess}}, (HS1)_{p'}, (HS3)_{p'} \) and \((HS1)_{\omega}, (HS2)_{\omega} \) are all satisfied. Pick any matrix \( A \in \mathbb{R}^{d \times d} \). Suppose that either \((\sigma_1, \sigma_2) = (1,0) \) with
\[
f(u_{i+1,j}, u_{i,j+1}, u_{i-1,j}, u_{i,j-1}, u_{i,j}) = A[u_{i,j+1} + u_{i-1,j} + u_{i,j-1}],
\]
\[
of(u_{i+1,j}, u_{i,j+1}, u_{i-1,j}, u_{i,j-1}, u_{i,j}) = A[u_{i,j} + u_{i-1,j} + u_{i,j-1}],
\]
or that \((\sigma_1, \sigma_2) = (0,1) \) with
\[
of(u_{i+1,j}, u_{i,j+1}, u_{i-1,j}, u_{i,j-1}, u_{i,j}) = A[u_{i+1,j} + u_{i,j+1} + u_{i,j-1} + u_{i,j-1}],
\]  
\[
(2.48) \quad (2.49) \quad (2.50)
\]
Then we have \( \partial \omega \phi_\omega = 0 \). In addition, the statements in Theorem 2.4 all hold, after replacing (v) by
\[
(v') \quad \text{The function } v = w \text{ satisfies the estimates}
\]
\[
\| w(t) \|_{L^p(Z; \mathbb{R}^d)} \leq C(1 + t)^{-5/4} \| v^0 \|_{L^p(Z; \mathbb{R}^d)}, \\
\| w(t) \|_{L^\infty(Z; \mathbb{R}^d)} \leq C(1 + t)^{-3/2} \| v^0 \|_{L^p(Z; \mathbb{R}^d)}.
\]  
(2.51)

In the special case that \( \sigma \) is one of the lattice directions \((1,0)\) or \((0,1)\) and moreover the coupling in the transverse direction is linear with weights that are equal both across components in the vector \( u \) and from one neighbour to the other, we obtain stronger decay. While this case is certainly restrictive, it also holds in our motivating example (1.1) and so we state it here as a theorem.
\textbf{Theorem 2.6.} Consider the LDE (2.1) and suppose that (Hf), (HΦ), (HS)_{ess}, and (HS1)_{p},(HS3)_{p} are all satisfied. Pick any constant \( \kappa > 0 \). Suppose that either \((\sigma_1, \sigma_2) = (1, 0)\) with
\[
\begin{align*}
f(u_{i+1,j}, u_{i,j+1}, u_{i-1,j}, u_{i,j-1}, u_{ij}) &= \kappa [u_{i,j+1} + u_{i-1,j}] + g(u_{i+1,j}, u_{i-1,j}, u_{ij}),
\end{align*}
\] (2.52)
or that \((\sigma_1, \sigma_2) = (0, 1)\) with
\[
\begin{align*}
f(u_{i+1,j}, u_{i,j+1}, u_{i-1,j}, u_{i,j-1}, u_{ij}) &= \kappa [u_{i+1,j} + u_{i-1,j}] + g(u_{i+1,j}, u_{i-1,j}, u_{ij}).
\end{align*}
\] (2.53)
Then the triplets \((\lambda, \phi, \psi)\) are defined for all \( \omega \in [-\pi, \pi] \) and we have \( \phi_\omega = \phi \) for all \( \omega \in [-\pi, \pi] \).
In addition, the statements in Theorem 2.4 all hold, after replacing (v) by
(v)’ The function \( v = w \) satisfies the estimates
\[
\begin{align*}
\|w(t)\|_{L^p(\mathbb{Z}^2;\mathbb{R}^d)} &\leq C(1 + t)^{-7/4} \|v^0\|_{L^p(\mathbb{Z}^2;\mathbb{R}^d)}, \\
\|w(t)\|_{L^p(\mathbb{Z}^2;\mathbb{R}^d)} &\leq C(1 + t)^{-7/4} \|v^0\|_{L^p(\mathbb{Z}^2;\mathbb{R}^d)}.
\end{align*}
\] (2.54)

\section{3 Coordinate System}

In this section we develop the coordinate system that we use to analyze the planar nonlinear LDE (2.1). We start by introducing the new coordinates
\[
\begin{align*}
n &= i\sigma_1 + j\sigma_2, \\
l &= i\sigma_2 - j\sigma_1.
\end{align*}
\] (3.1)
The first of these coordinates represents the direction parallel to the propagation of the wave, while the second coordinate represents the direction perpendicular to wave motion. In the sequel we refer to \( n \) as the wave coordinate and \( l \) as the transverse coordinate.

We emphasize that we always have \((n, l) \in \mathbb{Z}^2 \) due to our assumption that \((\sigma_1, \sigma_2) \in \mathbb{Z}^2 \). However, the inverse of the transformation (3.1) is given by
\[
\begin{align*}
i &= \frac{1}{\sigma_1^2 + \sigma_2^2}(n\sigma_1 + l\sigma_2), \\
j &= \frac{1}{\sigma_1^2 + \sigma_2^2}(n\sigma_2 - l\sigma_1),
\end{align*}
\] (3.2)
which means that the pairs \((n, l)\) in the range of the transformation (3.1) represent only a sublattice of \( \mathbb{Z}^2 \). Indeed, rewriting the LDE (2.1) in terms of our new coordinates, we obtain the system
\[
\begin{align*}
\dot{u}_{nl}(t) &= f\left(\pi_{nl}^X u(t)\right),
\end{align*}
\] (3.3)
in which the linear operator \( \pi_{nl}^X : \ell^\infty(\mathbb{Z}^2;\mathbb{R}^d) \to (\mathbb{R}^d)^5 \) is given by
\[
\pi_{nl}^X u = \left(u_{n+\sigma_1,l+\sigma_2}, u_{n+\sigma_2,l-\sigma_1}, u_{n-\sigma_1,l+\sigma_2}, u_{n-\sigma_2,l-\sigma_1}, u_{nl}\right).
\] (3.4)
As an example, the new coordinates transform the discrete Nagumo LDE (1.1) into the system
\[
\begin{align*}
\dot{u}_{nl} = [\Delta^X u]_{nl} + g(u_{nl}(t)),
\end{align*}
\] (3.5)
in which
\[
[\Delta^X u]_{nl} = u_{n+\sigma_1,l+\sigma_2} + u_{n+\sigma_2,l-\sigma_1} + u_{n-\sigma_1,l-\sigma_2} + u_{n-\sigma_2,l+\sigma_1} - 4u_{nl}.
\] (3.6)
To avoid clutter, we also introduce the operator
\[
\pi^X : \ell^\infty(\mathbb{Z}^2;\mathbb{R}^d) \to \ell^\infty(\mathbb{Z}^2,(\mathbb{R}^d)^5)
\] (3.7)
that acts as
\[ [\pi^x u]_{nl} = \pi^x_n u. \] (3.8)

The operator \( \pi^x \) should be regarded as a shorthand for generating a stencil of grid points. Note that when \((\sigma_1, \sigma_2)\) is equal to \((0, 1)\) or \((1, 0)\), we have \(\pi^x = \pi^+\) as introduced in §2. Lifting the nonlinearity \(f\) in the obvious fashion to act on \(\ell^\infty(\mathbb{Z}^2; (\mathbb{R}^d)^5)\) instead of \((\mathbb{R}^d)^5\), we can now rephrase (3.3) in the compact form
\[ \dot{u}(t) = f(\pi^x u(t)). \] (3.9)

In the sequel, we often refer to (3.3) as an equation in local form, while (3.9) is called an equation in global form.

Let us now consider any bounded function \(\zeta : \mathbb{R} \to \mathbb{R}\), where we will use both \(s = d\) and \(s = 5d\). For any shift \(\vartheta \in \mathbb{R}\), we introduce the sequence \(T_\vartheta \zeta \in \ell^\infty(\mathbb{Z}; \mathbb{R}^s)\) that is defined by
\[ [T_\vartheta \zeta]_n = \zeta(n + \vartheta). \] (3.10)

In particular, \(T_\vartheta \) converts a function defined on \(\mathbb{R}\) into a sequence by evaluating the function at the points \(\mathbb{Z} + \vartheta\). Furthermore, for any \(\theta \in \ell^\infty(\mathbb{Z}; \mathbb{R})\), we write \(T_\theta \zeta \in \ell^\infty(\mathbb{Z}^2; \mathbb{R}^s)\) for the planar sequence that is defined by
\[ [T_\theta \zeta]_{nl} = \zeta(n + \theta_l). \] (3.11)

By interpreting a shift \(\vartheta \in \mathbb{R}\) as a constant sequence in \(\ell^\infty(\mathbb{Z}; \mathbb{R})\), we note that we can also write \(T_\vartheta \zeta \in \ell^\infty(\mathbb{Z}^2; \mathbb{R}^s)\) to represent the planar sequence
\[ [T_\vartheta \zeta]_{nl} = \zeta(n + \vartheta), \] (3.12)
which is constant in the second coordinate.

Using this notation, we observe that the travelling wave solution \(u_{nl}(t) = \Phi(n + ct)\) to (3.9) can be written as
\[ u(t) = T_{ct} \Phi. \] (3.13)

In order to understand the stability of this travelling wave, we set out to seek solutions to (3.9) that can be written as
\[ u(t) = T_{ct + \theta(t)} \Phi + v(t), \] (3.14)
which in local form is equivalent to
\[ u_{nl}(t) = \Phi(n + ct + \theta_l(t)) + v_{nl}(t). \] (3.15)

Here the function
\[ \theta : [0, \infty) \to \ell^\infty(\mathbb{Z}; \mathbb{R}) \] (3.16)
represents a deformation of the travelling wave profile in the transverse direction, while the remainder function
\[ v : [0, \infty) \to \ell^\infty(\mathbb{Z}^2; \mathbb{R}^d) \] (3.17)
contains any perturbations that are 'transverse' to this deformation in an appropriate sense. Indeed, allowing \(\theta\) to vary in \(\ell^\infty(\mathbb{Z}; \mathbb{R})\) buys us \(\mathbb{Z}\)-many degrees of freedom which we can use to restrict \(v\) to live in a favourable subspace.

In order to describe the different norms we employ for the function \(v\), we introduce the sequence spaces
\[ X_{p,q} = \ell^p(\mathbb{Z}; \ell^q(\mathbb{Z}; \mathbb{R}^d)), \] (3.18)
parametrized by pairs of exponents \(1 \leq p \leq \infty\) and \(1 \leq q \leq \infty\). A sequence \(v \in X_{p,q}\) can be interpreted as a planar sequence \(v \in \ell^\infty(\mathbb{Z}^2; \mathbb{R}^d)\) by the identification
\[ v_{nl} = (v_n)_l. \] (3.19)
In particular, the $\ell^p$ norm is taken along the direction of the wave and the $\ell^q$ norm is taken in the transverse direction.

Before we can describe the relation between $\theta$ and $v$, we need to introduce a number of operators. First of all, for any $\vartheta \in \mathbb{R}$ and any $1 \leq p \leq \infty$, we write
\[
Q_{\vartheta} : \ell^p(\mathbb{Z}; \mathbb{R}^d) \rightarrow \mathbb{R}
\]
for the bounded linear operator that acts as
\[
Q_{\vartheta} v = \sum_{n \in \mathbb{Z}} \langle \psi(n + \vartheta), v_n \rangle.
\] (3.21)
This operator is well-defined as a consequence of the fact that the adjoint eigenfunction $\psi(\xi)$ decays at an exponential rate as $\xi \rightarrow \pm \infty$. This decay also allows us to view $Q_{\vartheta}$ as a bounded linear map
\[
Q_{\vartheta} : \mathcal{X}_{p,q} \rightarrow \ell^q(\mathbb{Z}; \mathbb{R})
\] (3.22)
by writing
\[
[Q_{\vartheta} v]_l = \sum_{n \in \mathbb{Z}} \langle \psi(n + \vartheta), v_{nl} \rangle.
\] (3.23)
In particular, $Q_{\vartheta}$ acts only on the direction of propagation of the wave. Associated to $Q_{\vartheta}$, we can introduce the operator
\[
P_{\vartheta} = \left[ T_{\vartheta} \phi \right] Q_{\vartheta}
\] (3.24)
which can be seen either as a bounded linear map
\[
P_{\vartheta} : \ell^p(\mathbb{R}, \mathbb{R}^d) \rightarrow \ell^p(\mathbb{R}, \mathbb{R}^d)
\] (3.25)
or as a bounded linear map
\[
P_{\vartheta} : \mathcal{X}_{p,q} \rightarrow \mathcal{X}_{p,q}
\] (3.26)
by writing
\[
[P_{\vartheta} v]_n = \left[ T_{\vartheta} \phi \right]_n [Q_{\vartheta} v]_l = \phi(n + \vartheta) \sum_{n' \in \mathbb{Z}} \langle \psi(n' + \vartheta), v_{n'n} \rangle.
\] (3.27)
For convenience, we also introduce the operators
\[
Q'_{\vartheta} : \mathcal{X}_{p,q} \rightarrow \ell^q(\mathbb{Z}; \mathbb{R})
\] (3.28)
which arise in the course of computing time derivatives of $Q_{ct}$ and act as
\[
[Q'_{\vartheta} v]_l = \sum_{n \in \mathbb{Z}} \langle \psi'(n + \vartheta), v_{nl} \rangle.
\] (3.29)
Note that $\psi'(\xi)$ also decays exponentially as $\xi \rightarrow \pm \infty$, which can be deduced from the MFDE satisfied by $\psi$. Finally, we write
\[
P'_{\vartheta} : \mathcal{X}_{p,q} \rightarrow \mathcal{X}_{p,q}
\] (3.30)
for the associated operators $P'_{\vartheta} = \left[ T_{\vartheta} \phi \right] Q'_{\vartheta}$ that act as
\[
[P'_{\vartheta} v]_n = \left[ T_{\vartheta} \phi \right]_n [Q'_{\vartheta} v]_l = \phi(n + \vartheta) \sum_{n' \in \mathbb{Z}} \langle \psi'(n' + \vartheta), v_{n'n} \rangle.
\] (3.31)
Notice that (2.25) implies that
\[
Q_{\vartheta} T_{\vartheta} \phi = 1
\] (3.32)
for all $\vartheta \in \mathbb{R}$. In particular, we have the identity $P^2_{\vartheta} = P_{\vartheta}$, both in $\mathcal{L}(\ell^p(\mathbb{Z}; \mathbb{R}^d))$ and $\mathcal{L}(\mathcal{X}_{p,q})$. In fact, the operator $P_{\vartheta}$ can be seen as the spectral projection onto the neutral mode for the
linearization of (2.1) about \( T_\ell \Phi \) when posed on the subspace of \( \ell^\infty(\mathbb{Z}^2; \mathbb{R}^d) \) that contains only sequences that are constant in the transverse direction. Here we are interested in the case when arbitrary perturbations are considered, in which case zero is no longer an isolated eigenvalue and the spectral projection does not exist in a classical sense. Rather the projection \( P_\theta \) can be thought of as a crude approximation of what the spectral projection onto the origin wants to be. See [6, 37] for more examples of extending spectral projections through the essential spectrum. Let us emphasize here that \( P_\phi \) is not a projection.

### 3.1 Equations for \( v \) and \( \theta \)

We are now ready to describe the relation between \( v(t) \) and \( \theta(t) \). The goal is to eliminate the neutral mode in the best way that we can that does not complicate the eventual Fourier synthesis. To this end, we introduce for any \( 1 \leq p \leq \infty \) and \( q \in \{2, \infty\} \) the subspace

\[
\mathcal{X}_{p,q}^\perp(t) = \{ v \in \mathcal{X}_{p,q} \mid Q_{ct}v = 0 \in \ell^q(\mathbb{Z}; \mathbb{R}) \}
\]

and demand \( v(t) \in \mathcal{X}_{p,q}^\perp(t) \). As we shall see below, this condition is sufficient to fix the dynamics of both \( \theta \) and \( v \) as long as these functions are both sufficiently small. In particular, the pair \((v, \theta) \in \mathcal{X}_{p,q}^\perp \times \ell^q(\mathbb{Z}; \mathbb{R})\) form coordinates for the solution \( u \) in a tubular neighbourhood of the wave profile \( \Phi \).

Differentiating the Ansatz (3.15), we find that

\[
\dot{u}_{nl}(t) = (c + \dot{\theta}_l(t)) \Phi'(n + ct + \theta_l(t)) + \dot{v}_{nl}(t) = f(\tau \Phi)(n + ct + \theta_l(t)) + \dot{\theta}_l(t) \phi(n + ct + \theta_l(t)) + \dot{v}_{nl}(t),
\]

which we abbreviate as

\[
\dot{u}(t) = f(T_{ct+\theta(t)} \tau \Phi) + \dot{\theta}(t)T_{ct+\theta(t)} \phi + \dot{v}(t),
\]

using the convention that the product of a sequence \( \theta \in \ell^\infty(\mathbb{Z}; \mathbb{R}) \) with a planar sequence \( v \in \mathcal{X}_{p,\infty} \) is given by \( [\theta v]_{nl} = \theta_l v_{nl} \). Imposing the condition that the Ansatz (3.15) is a true solution to the LDE (3.9), we obtain the following evolution equation for \( v \):

\[
v(t) = f(\pi^\perp T_{ct+\theta(t)} \Phi + \pi^\perp v(t)) - f(T_{ct+\theta(t)} \tau \Phi) - \dot{\theta}(t)T_{ct+\theta(t)} \phi.
\]

It is desirable to write the term \( f(y) - f(x) \) as \( f'(x)(y - x) + O((y - x)^2) \). To this end we analyze the difference \( T_{ct}(\pi^\perp T_\theta - T_\theta \tau) \Phi \) which when added to \( \pi^\perp v \) gives us the relevant \((x-y)\) in our Taylor expansion. Note that \( T_\theta \) does not commute with \( \pi^\perp \) or \( \tau \) because \( \theta \) is in general \( l \)-dependent. This difference is a vector of differences of the wave profile, the first term of which is \( \Phi(\xi + \sigma_1 + \theta_{l+\sigma_2}) - \Phi(\xi + \sigma_1 + \theta_l) \), the other terms being similar except with different indices on and signs in front of the \( \sigma_j \). To lowest order this term factors as the product \( \Phi'(\xi + \sigma_1)(\theta_{l+\sigma_2} - \theta_l) \). This is the first time that the anisotropy of the lattice complicates our analysis. Firstly, the coefficient on \( (\theta_{l+\sigma_2} - \theta_l) \) is \( \Phi'(\xi - \sigma_1) \neq \Phi'(\xi + \sigma_1) \) and hence the two slowly decaying first differences \( (\theta_{l+\sigma_2} - \theta_l) \) do not combine to form a relatively rapidly decaying second difference \( \theta_{l+\sigma_2} + \theta_{l-\sigma_2} - 2\theta_l \) (unless of course \( \sigma_1 = 0 \)). Secondly, because the coefficients on the first differences do not have identical behaviour in the wave direction, this term cannot be projected away by imposing an orthogonality condition on \( v \) that is uniform in \( l \).

We now introduce notation that allows us to decompose the vector of differences \( T_{ct}(\pi^\perp T_\theta - T_\theta \tau) \Phi \) and more generally the right hand side of (3.36) into linear terms that generate the evolution semigroup, nonlinear terms whose estimation requires care, and nonlinear terms which are estimated relatively easily.

We use the notation \( \theta^\circ \in \ell^\infty(\mathbb{Z}; \mathbb{R}^5) \) to refer to the sequence

\[
\theta^\circ_l = (\theta_{l+\sigma_2} - \theta_l, \theta_{l-\sigma_1} - \theta_l, \theta_{l-\sigma_2} - \theta_l, \theta_{l+\sigma_1} - \theta_l, 0) \in \mathbb{R}^5.
\]
In all of our applications the 5th coordinate is zero, but we include the 5th coordinate so that dimensions match. A short computation shows that

$$[\pi^X T_{ct+\theta} \Phi - T_{ct+\theta} \tau \Phi]_{nl} = [\mathcal{T}(\theta_c^I) \Phi(\cdot + ct + \theta_I)]_n,$$

(3.38)
in which we have introduced the symbol

$$\mathcal{T}(\alpha) = (T_{\sigma_1+\alpha_1} - T_{\sigma_1}, T_{\sigma_2+\alpha_2} - T_{\sigma_2}, T_{-\sigma_1+\alpha_3} - T_{-\sigma_1}, T_{-\sigma_2+\alpha_4} - T_{-\sigma_2}, 0),$$

(3.39)
for any $$\alpha = (\alpha_1, \ldots, \alpha_5) \in \mathbb{R}^5$$. For any $$n \in \mathbb{Z}$$ and $$\vartheta \in \mathbb{R}$$, we now introduce the linear operator $$M(n, \vartheta): \mathbb{R}^5 \to (\mathbb{R}^d)^5$$ that acts as

$$M(n, \vartheta) \alpha = [(\alpha_1 T_{\sigma_1}, \alpha_2 T_{\sigma_2}, \alpha_3 T_{-\sigma_1}, \alpha_4 T_{-\sigma_2}, 0) \phi(\cdot + \vartheta)]_n$$

$$= (\alpha_1 \phi(\vartheta + n + \sigma_1), \alpha_2 \phi(\vartheta + n + \sigma_2), \alpha_3 \phi(\vartheta + n - \sigma_1), \alpha_4 \phi(\vartheta + n - \sigma_2), 0).$$

(3.40)
Upon introducing the nonlinear function $$\mathcal{M}: \mathbb{Z} \times \mathbb{R} \times \mathbb{R}^5 \to (\mathbb{R}^d)^5$$ given by

$$\mathcal{M}(n, \vartheta; \alpha) = [\mathcal{T}(\alpha) \Phi(\cdot + \vartheta)]_n - M(n, \vartheta) \alpha,$$

(3.41)
the fact that $$\Phi''$$ is bounded yields the estimate

$$\mathcal{M}(n, \vartheta; \alpha) = O(|\alpha|^2), \quad \alpha \to 0,$$

(3.42)
which holds uniformly for $$n \in \mathbb{Z}$$ and $$\vartheta \in \mathbb{R}$$. We have hence obtained

$$[\pi^X T_{ct+\theta} \Phi - T_{ct+\theta} \tau \Phi]_{nl} = M(n, ct + \theta_I) \theta_c^I + \mathcal{M}(n, ct + \theta_I; \theta_c^I),$$

(3.43)
which we write in global form as

$$\pi^X T_{ct+\theta} \Phi - T_{ct+\theta} \tau \Phi = M(ct + \theta) \theta_c^o + \mathcal{M}(ct + \theta; \theta_c^o).$$

(3.44)
Thus (3.36) may be rewritten informally as

$$\dot{v} = L[\pi^X v + M\theta_c^o + \mathcal{M}] + \mathcal{N}(\pi^X v + M\theta_c^o + \mathcal{M})$$

(3.45)
where we have introduced some new notation. The linear operator $$L$$ is given in local form by

$$L(n, \vartheta)v = Df([\tau \Phi](n + \vartheta))v,$$

(3.46)
while the nonlinear $$\mathcal{N}$$, given by

$$\mathcal{N}(n, \vartheta; v) = f([\tau \Phi](n + \vartheta) + v) - f([\tau \Phi](n + \vartheta)) - Df([\tau \Phi](n + \vartheta))v,$$

(3.47)
enjoys the estimate

$$\mathcal{N}(n, \vartheta; v) = O(|v|^2), \quad v \to 0,$$

(3.48)
which is uniform for $$n \in \mathbb{Z}$$ and $$\vartheta \in \mathbb{R}$$ and follows from the $$C^2$$-smoothness of $$f$$ together with the uniform boundedness of $$\Phi$$. We now begin the process of separating the terms which are easy to estimate from those that require more care by writing

$$\dot{v}(t) = L(ct + \theta(t))[\pi^X v(t) + M(ct + \theta(t)) \theta_c^o(t)] - \dot{\theta}(t) T_{ct+\theta(t)} \Phi$$

$$+ \mathcal{R}_{1,ct}(v(t), \theta(t)),$$

(3.49)
in which the nonlinearity $$\mathcal{R}_{1,ct}: \ell^\infty(\mathbb{Z}^2; \mathbb{R}^d) \times \ell^\infty(\mathbb{Z}; \mathbb{R}) \to \ell^\infty(\mathbb{Z}^2; \mathbb{R}^d)$$ acts as

$$[\mathcal{R}_{1,ct}(v, \theta)]_{nl} = L(n, ct + \theta_I) \mathcal{M}(n, ct + \theta_I; \theta_c^I)$$

$$+ \mathcal{N}(n, ct + \theta_I; \pi^X v + M(n, ct + \theta_I) \theta_c^o + \mathcal{M}(n, ct + \theta_I; \theta_c^I)).$$

(3.50)
We now set out to derive an expression for \( \dot{\theta}_t \). Differentiating the condition \( Q_{ct}v(t) = 0 \) shows that
\[
Q_{ct}\dot{v}(t) + cQ'_{ct}v(t) = 0 \in \ell^\infty(Z; \mathbb{R}).
\] (3.51)
Substitution of (3.49) yields the system
\[
\dot{\theta}(t)Q_{ct}T_{ct+\theta(t)\phi} = Q_{ct}L(ct + \theta(t))[\pi^x v(t) + M(ct + \theta(t))\theta^\circ] + cQ'_{ct}v + Q_{ct}\mathcal{R}_{1,ct}(v(t), \theta(t)).
\] (3.52)
Observe that for each \( l \) and at each time \( t \), the quantity \( Q_{ct}T_{ct+\theta(t)\phi} \) is merely a number that can be divided away to isolate \( \dot{\theta}_t \). In view of the identity \( Q_{ct}T_{ct} = 1 \), the uniform bound on \( \Phi'' = \phi'' \) implied by \( \Phi, H, (2.7) \) and (2.5) and the expansion \( \frac{1}{1+\phi} = 1 - \varepsilon + O(\varepsilon^2) \), we can pick a small \( \delta_\theta > 0 \) and introduce functions \( V_\theta : (-\delta_\theta, \delta_\theta) \to \mathbb{R} \) that are fixed by the relation
\[
[Q_{ct}T_{ct+\theta(t)\phi}]^{-1} - 1 = -\theta_t Q_{ct}T_{ct}\phi' + V_{ct}(\theta_t).
\] (3.53)
These functions satisfy the bounds
\[
V_\phi(\theta_t) = O(|\theta_t|^2), \quad \theta_t \to 0,
\] (3.54)
uniformly for \( \theta \in \mathbb{R} \) and can be extended to map \( \ell^\infty(Z; (-\delta_\theta, \delta_\theta)) \) into \( \ell^\infty(Z; \mathbb{R}) \). Using these functions to rewrite (3.52), we obtain
\[
\dot{\theta}(t) = Q_{ct}L(ct + \theta(t))[\pi^x v(t) + M(ct + \theta(t))\theta^\circ] + cQ'_{ct}v + Q_{ct}\mathcal{R}_{1,ct}(v(t), \theta(t)),
\] (3.55)
in which the nonlinearity \( S_{1,ct} : \ell^\infty(Z; \mathbb{R}^d) \times \ell^\infty(Z; (-\delta_\theta, \delta_\theta)) \to \ell^\infty(Z; \mathbb{R}) \) is defined by
\[
S_{1,ct}(v, \theta) = (1 - \theta_t Q_{ct}T_{ct} \phi' + V_{ct}(\theta_t))Q_{ct}R_{1,ct}(v, \theta) + cV_{ct}(\theta)Q'_{ct}v + V_{ct}(\theta)Q_{ct}L(ct + \theta)\pi^x v + M(ct + \theta)\theta^\circ.
\] (3.56)
Notice that we are explicitly excluding terms of order \( O(\theta v) \) and \( O(\theta^\circ) \) from the nonlinearity \( S_{1,ct} \) because these terms require special treatment in our nonlinear stability analysis; see §5.
Plugging (3.55) back into (3.49), we arrive at
\[
\dot{v}(t) = [I - P_{ct}]L(ct + \theta(t))[\pi^x v(t) + M(ct + \theta(t))\theta^\circ] - cP'_{ct}v(t) + Q_{ct}\mathcal{R}_{2,ct}(v(t), \theta(t)),
\] (3.57)
in which the nonlinearity \( R_{2,ct} : \ell^\infty(Z; \mathbb{R}^d) \times \ell^\infty(Z; (-\delta_\theta, \delta_\theta)) \to \ell^\infty(Z; \mathbb{R}^d) \) acts as
\[
R_{2,ct}(v, \theta) = R_{1,ct}(v, \theta) + \theta T_{ct+\theta(t)}\phi Q_{ct}T_{ct+\theta(t)}Q_{ct}L(cp + \theta(t))[\pi^x v(t) + M(cp + \theta(t))\theta^\circ(t)] + cP'_{ct}v(t)
+ c\theta T_{ct+\theta(t)}\phi Q_{ct}T_{ct+\theta(t)}Q'_{ct}v(t)
- [T_{ct+\theta(t)} - T_{ct}]\phi S_{1,ct}(v(t), \theta(t)) + c[T_{ct+\theta(t)} - T_{ct}]\phi Q'_{ct}v(t).
\] (3.58)
Notice that we are absorbing the \( O(\theta v) \) and \( O(\theta^\circ) \) terms into the nonlinearity \( R_{2,ct} \), in contrast to our expression (3.55) for \( \dot{\theta}_t \).
The next step is to expand the linear operators $L(\vartheta)$ and $M(\vartheta)$ around $\vartheta = ct$. In particular, we write

$$L_{ct} = L(ct), \quad M_{ct} = M(ct)$$

and obtain the system

$$\dot{v}(t) = [I - P_{ct}]L_{ct}[\pi^v v(t) + M_{ct}\theta^\circ(t)] - cP_{ct}'v(t)$$

$$\dot{\theta}(t) = Q_{ct}L_{ct}[\pi^v v(t) + M_{ct}\theta^\circ(t)] + cQ_{ct}'v(t) + \theta H_{3,ct}[v(t), \theta(t)] + S_{3,ct}(v(t), \theta(t)).$$

Here we have introduced the linear operators $H_{3,ct} : \ell^\infty(\mathbb{Z}^2; \mathbb{R}^d) \times \ell^\infty(\mathbb{Z}; \mathbb{R}^5) \to \ell^\infty(\mathbb{Z}; \mathbb{R})$ that act as

$$H_{3,ct}[v, \theta] = Q_{ct}L_{ct}[\partial_\vartheta L(\vartheta)]_{\vartheta = ct}[\pi^v v + M_{ct}\theta^\circ] + Q_{ct}L_{ct}[\partial_\vartheta M(\vartheta)]_{\vartheta = ct}\theta^\circ$$

$$-Q_{ct}T_{ct}\psi Q_{ct}L_{ct}[\pi^v v + M_{ct}\theta^\circ] - cQ_{ct}T_{ct}\psi Q_{ct}'v,$$

together with the nonlinearities $R_{3,ct} : \ell^\infty(\mathbb{Z}^2; \mathbb{R}^d) \times \ell^\infty(\mathbb{Z}; (-\delta_\theta, \delta_\theta)) \to \ell^\infty(\mathbb{Z}; \mathbb{R})$ given by

$$R_{3,ct}(v, \theta) = R_{2,ct}(v, \theta) + [I - P_{ct}][L(ct + \theta) - L(ct)][\pi^v v + M(ct + \theta)\theta^\circ] + [I - P_{ct}]L_{ct}[M(ct + \theta) - M(ct)]\theta^\circ$$

and the nonlinearities $S_{3,ct} : \ell^\infty(\mathbb{Z}^2; \mathbb{R}^d) \times \ell^\infty(\mathbb{Z}; (-\delta_\theta, \delta_\theta)) \to \ell^\infty(\mathbb{Z}; \mathbb{R})$ defined by

$$S_{3,ct}(v, \theta) = S_{1,ct}(v, \theta) + Q_{ct}[L(ct + \theta) - L(ct) - \theta[\partial_\vartheta L(\vartheta)]_{\vartheta = ct}][\pi^v v + M(ct + \theta)\theta^\circ]$$

$$+Q_{ct}L_{ct}[M(ct + \theta) - M(ct) - \theta[\partial_\vartheta M(\vartheta)]_{\vartheta = ct}]\theta^\circ$$

$$-\theta Q_{ct}T_{ct}\psi Q_{ct}[L(ct + \theta) - L(ct)][\pi^v v + M(ct + \theta)\theta^\circ] - \theta Q_{ct}T_{ct}\psi Q_{ct}L_{ct}[M(ct + \theta) - M(ct)]\theta^\circ.$$

Our final step consists of rewriting the linear operator $H_{3,ct}$ in such a way that the nonlinear analysis in §5 is simplified. In particular, we reuse the symbol $\tau$ to write

$$[\tau v]_{nl} = (v_{n+\sigma_1, j} + v_{n+\sigma_2, j}, v_{n-\sigma_1, j}, v_{n-\sigma_2, j}, v_{n, l}) \in \mathbb{R}^5$$

for any $v \in \ell^\infty(\mathbb{Z}^2; \mathbb{R}^d)$. Notice that unlike $\pi^v$, the operator $\tau$ does not act on the transverse direction $\ell \in \mathbb{Z}$. Indeed, for any $v \in \ell^\infty(\mathbb{Z}^2; \mathbb{R}^d)$ we have the identity

$$\pi^v v = \tau v + \tau \cdot v^\circ,$$

in which

$$[v^\circ]_{nl} = (v_{n, l+\sigma_2} - v_{n, l}, v_{n, l-\sigma_1} - v_{n, l}, v_{n, l-\sigma_2} - v_{n, l}, v_{n, l+\sigma_1} - v_{n, l}, 0),$$

while the dot product is defined in the obvious manner. A short computation shows that

$$Q_{ct}L_{ct}\tau v = \sum_{n \in \mathbb{Z}}(\psi(n + ct), Df([\tau\Phi](n + ct)))[\psi v]_{nl}$$

$$= \sum_{n \in \mathbb{Z}}Df([\tau\Phi](n + ct))\tau^* v](n + ct), v_{nl})$$

$$= \sum_{n \in \mathbb{Z}}(-c\psi'(n + ct), v_{nl})$$

$$= -cQ_{ct}'v.$$
In particular, we see that
\[
H_{4,ct}[v,0] = Q_{ct}[\partial_\theta L(\theta)]_{\theta=ct} \pi^x v - Q_{ct} T_{ct} \phi' Q_{ct} L_{ct} \tau \cdot v^o. \tag{3.68}
\]

Putting everything together, we finally arrive at the system
\[
\dot{v}(t) = \left[I - P_{ct}\right] L_{ct}[\pi^x v(t) + M_{ct} \theta^o(t)] - c P_{ct}' v(t) + \mathcal{R}_{4,ct}(v(t), \theta(t)),
\]
\[
\dot{\theta}(t) = Q_{ct} L_{ct}[\pi^x v(t) + M_{ct} \theta^o(t)] + c Q_{ct}' v(t) + \theta H_{4,ct}[\tau v(t), \theta^o(t)] + S_{4,ct}(v(t), \theta(t)). \tag{3.69}
\]

Here we have introduced the linear operators \(H_{4,ct} : \ell^\infty(Z^2, (\mathbb{R}^d)^{5}) \times \ell^\infty(Z; \mathbb{R}^5) \to \ell^\infty(Z; \mathbb{R})\) that act as
\[
H_{4,ct}[\tau v, \theta^o] = Q_{ct}[\partial_\theta L(\theta)]_{\theta=ct}[\tau v + M_{ct} \theta^o] + Q_{ct} L_{ct}[\partial_\theta M(\theta)]_{\theta=ct} \theta^o - Q_{ct} T_{ct} \phi' Q_{ct} L_{ct} M_{ct} \theta^o \tag{3.70}
\]
and are bounded uniformly for \(t \in \mathbb{R}\). In addition, after picking a smooth cut-off function \(\chi^c : [0, \infty) \to [0, 1]\) that has
\[
\chi^c([0, 1]) = 1, \quad \chi^c([2, \infty)) = 0, \tag{3.71}
\]
we have introduced the nonlinearities \(\mathcal{R}_{4,ct} : \ell^\infty(Z^2; \mathbb{R}^d) \times \ell^\infty(Z; \mathbb{R}) \to \ell^\infty(Z^2; \mathbb{R})\) given by
\[
\mathcal{R}_{4,ct}(v, \theta) = \chi^c\left(\|v\|_{\ell^\infty(Z^2; \mathbb{R}^d)} + 2\delta_0^{-1}\|\theta\|_{\ell^\infty(Z; \mathbb{R})}\right) \mathcal{R}_{3,ct}(v, \theta) \tag{3.72}
\]
and the nonlinearities \(S_{4,ct} : \ell^\infty(Z^2; \mathbb{R}^d) \times \ell^\infty(Z; \mathbb{R}) \to \ell^\infty(Z; \mathbb{R})\) defined by
\[
S_{4,ct}(v, \theta) = \chi^c\left(\|v\|_{\ell^\infty(Z^2; \mathbb{R}^d)} + 2\delta_0^{-1}\|\theta\|_{\ell^\infty(Z; \mathbb{R})}\right) S_{3,ct}(v, \theta) + \theta Q_{ct}[\partial_\theta L(\theta)]_{\theta=ct}[\tau \cdot v^o] - \theta Q_{ct} T_{ct} \phi' Q_{ct} L_{ct} \tau \cdot v^o. \tag{3.73}
\]

We emphasize that the introduction of the cut-offs serves as a notational convenience only. In particular, they allow us to formulate the following global bounds on the nonlinearities.

**Proposition 3.1.** Suppose that (HF), (HF$^\epsilon$), (HS)$_{\text{ess}}$ and (HS)$_p$ (HS$^3_p$) are satisfied and pick \(1 \leq p \leq \infty\). There exists a constant \(C > 0\) such that for any \(t \in \mathbb{R}, v \in X_{p,2}^{\pi^x}\) and \(\theta \in \ell^2(Z; \mathbb{R})\) we have the bounds
\[
\|\mathcal{R}_{4,ct}(v, \theta)\|_{X_{p,1}} \leq C\left(\|v\|_{X_{p,2}} + \|\theta^o\|_{\ell^2(Z; \mathbb{R}^5)} + \|\theta\|_{\ell^2(Z; \mathbb{R})}\right) \left(\|v\|_{X_{p,2}} + \|\theta^o\|_{\ell^2(Z; \mathbb{R}^5)}\right),
\]
\[
\|\mathcal{R}_{4,ct}(v, \theta)\|_{X_{p,2}} \leq C\left(\|v\|_{X_{p,2}} + \|\theta^o\|_{\ell^2(Z; \mathbb{R}^5)} + \|\theta\|_{\ell^2(Z; \mathbb{R})}\right) \left(\|v\|_{X_{p,\infty}} + \|\theta^o\|_{\ell^\infty(Z; \mathbb{R}^5)}\right), \tag{3.74}
\]

together with
\[
\|S_{4,ct}(v, \theta)\|_{\ell^1(Z; \mathbb{R})} \leq C\left(\|\theta\|_{\ell^2(Z; \mathbb{R})} \|\theta^o\|_{X_{p,2}} + C\left(\|v\|_{X_{p,\infty}} + \|\theta^o\|_{\ell^\infty(Z; \mathbb{R}^5)}\right) \|\theta\|_{\ell^2(Z; \mathbb{R})}\right) + C\left(\|v\|_{X_{p,2}} + \|\theta^o\|_{\ell^2(Z; \mathbb{R}^5)}\right) \left(\|v\|_{X_{p,2}} + \|\theta^o\|_{\ell^\infty(Z; \mathbb{R}^5)}\right),
\]
\[
\|S_{4,ct}(v, \theta)\|_{\ell^2(Z; \mathbb{R})} \leq C\left(\|\theta\|_{\ell^2(Z; \mathbb{R})} \|\theta^o\|_{X_{p,2}} + C\left(\|v\|_{X_{p,\infty}} + \|\theta^o\|_{\ell^\infty(Z; \mathbb{R}^5)}\right) \|\theta\|_{\ell^2(Z; \mathbb{R})}\right) \|\theta\|_{\ell^\infty(Z; \mathbb{R})} + C\left(\|v\|_{X_{p,2}} + \|\theta^o\|_{\ell^2(Z; \mathbb{R}^5)}\right) \left(\|v\|_{X_{p,\infty}} + \|\theta^o\|_{\ell^\infty(Z; \mathbb{R}^5)}\right). \tag{3.75}
\]
Proof. Consider two arbitrary sequences $a, b \in \ell^2(\mathbb{Z}; \mathbb{R})$ and write $ab \in \ell^1(\mathbb{Z}; \mathbb{R})$ for the product sequence $|ab|_l = a_l b_l$. Using Cauchy-Schwartz and an elementary estimate it is easy to see that

\[
\|ab\|_{\ell^1(\mathbb{Z}; \mathbb{R})} \leq \|a\|_{\ell^2(\mathbb{Z}; \mathbb{R})} \|b\|_{\ell^2(\mathbb{Z}; \mathbb{R})}; \quad \|ab\|_{\ell^1(\mathbb{Z}; \mathbb{R})} \leq \|a\|_{\ell^2(\mathbb{Z}; \mathbb{R})} \|b\|_{\ell^\infty(\mathbb{Z}; \mathbb{R})}.
\] (3.76)

Another elementary estimate shows that

\[
\|a^2b\|_{\ell^1(\mathbb{Z}; \mathbb{R})} \leq \|a\|_{\ell^2(\mathbb{Z}; \mathbb{R})}^2 \|b\|_{\ell^\infty(\mathbb{Z}; \mathbb{R})}; \quad \|a^2b\|_{\ell^1(\mathbb{Z}; \mathbb{R})} \leq \|a\|_{\ell^2(\mathbb{Z}; \mathbb{R})} \|a\|_{\ell^\infty(\mathbb{Z}; \mathbb{R})} \|b\|_{\ell^\infty(\mathbb{Z}; \mathbb{R})}.
\] (3.77)

The exponential decay of $\phi(\xi)$ and $\phi'(\xi)$ as $\xi \to \pm \infty$ imply the inclusions $T_{ct,\phi} \in \ell^p(\mathbb{Z}; \mathbb{R}^d)$ and $T_{ct,\phi'} \in \ell^p(\mathbb{Z}; \mathbb{R}^d)$. In addition, the short-range interaction operators $\pi^x$ and $\pi^v$ are bounded as maps from $X_p,2$ into $X_p,2$. Finally, all long-range interactions featuring in $R_{4, ct}$ and $S_{4, ct}$ come from the linear operators $Q_{ct}$ and $Q'_{ct}$. These operators are bounded as maps from $X_p,2$ into $\ell^2(\mathbb{Z}; \mathbb{R})$. In particular, the bounds (3.74)-(3.75) follow directly from the estimates (3.76)-(3.77) upon inspection of the structure of $R_{4, ct}$ and $S_{4, ct}$.

We conclude this section by summarizing our discussion and explicitly stating the relation between our modified system (3.69) and the original LDE (2.1).

**Proposition 3.2.** Suppose that $(Hf)$, $(H\phi)$, $(HS)_{\text{ess}}$ and $(HS)_{\text{p}}$ are satisfied. Pick any $t_0 \in \mathbb{R}$ and consider any pair of functions $v : [t_0, \infty) \to \ell^\infty(\mathbb{Z}; \mathbb{R}^d)$ and $\theta : [t_0, \infty) \to \ell^\infty(\mathbb{Z}; \mathbb{R})$ for which $Q_{ct,0}v(t_0) = 0$ and for which the inequalities

\[
\|\theta(t)\|_{\ell^\infty(\mathbb{Z}; \mathbb{R})} \leq \frac{1}{2} \delta_\theta, \quad \|v(t)\|_{\ell^\infty(\mathbb{Z}; \mathbb{R}^d)} \leq \frac{1}{2}
\] (3.78)

hold for all $t \geq t_0$. Then if the pair $(v, \theta)$ satisfies (3.69), we have $Q_{ct}v(t) = 0$ for all $t \geq t_0$ and the function

\[
u_{ij}(t) = \phi(i\sigma_1 + j\sigma_2 + ct + \theta_{\sigma_2 - j\sigma_1}(t)) + v_{\sigma_1 + j\sigma_2,i\sigma_1 - j\sigma_1}(t)
\] (3.79)

satisfies the LDE (2.1) for all $t \geq t_0$.

**Proof.** Since $Q_{ct}P'_{ct} = Q'_{ct}$, we can compute

\[
\frac{d}{dt}[Q_{ct}v(t)] = cQ'_{ct}v(t) + Q_{ct}\dot{v}(t) = cQ'_{ct}v(t) + Q_{ct}P'_{ct}v(t) + Q_{ct}R_{4, ct}(v(t), \theta(t)) = Q_{ct}R_{4, ct}(v(t), \theta(t)) = Q_{ct}R_{2, ct}(v(t), \theta(t)) = 0.
\] (3.80)

The last equality can be verified directly from (3.58), in view of the restriction $|\theta_l(t)| < \delta_\theta$ for all $l \in \mathbb{Z}$, which shows that (3.53) is satisfied for all $t \geq t_0$. The fact that the function $u(t)$ solves (2.1) follows directly from the computations in this section.

## 4 Green’s functions

In this section we focus on the linear part of the system (3.69), which is given by

\[
\dot{v}(t) = [I - P_{ct}]L_{ct}[\pi^x v(t) + M_{ct}\theta^x(t)] - cP'_{ct}v(t)
\]

\[
\dot{\theta}(t) = Q_{ct}L_{ct}[\pi^x v(t) + M_{ct}\theta^x(t)] + cQ'_{ct}v(t).
\] (4.1)
Viewing this system as an ODE posed on $\ell^\infty(\mathbb{Z}^2; \mathbb{R}^d) \times \ell^\infty(\mathbb{Z}; \mathbb{R})$, it is clear that solutions are well-defined in forward and backward time since the linear operator on the right hand side is bounded uniformly for $t \in \mathbb{R}$. In particular, we can define a Green’s function

$$G(t, t_0) = \begin{pmatrix} G_{vv}(t, t_0) & G_{v\theta}(t, t_0) \\ G_{\theta v}(t, t_0) & G_{\theta\theta}(t, t_0) \end{pmatrix} \in \mathcal{L}(\ell^\infty(\mathbb{Z}^2; \mathbb{R}^d) \times \ell^\infty(\mathbb{Z}; \mathbb{R}))$$

(4.2)

by writing

$$\begin{pmatrix} v(t) \\ \theta(t) \end{pmatrix} = G(t, t_0) \begin{pmatrix} v_{t_0} \\ \theta_{t_0} \end{pmatrix}$$

(4.3)

for the unique solution to (4.1) that has the initial condition $v(t_0) = v_{t_0} \in \ell^\infty(\mathbb{Z}^2; \mathbb{R}^d)$ and $\theta(t_0) = \theta_{t_0} \in \ell^\infty(\mathbb{Z}; \mathbb{R})$.

Fixing $1 \leq p \leq \infty$, our goal is to restrict attention to initial conditions in the smaller spaces $\mathcal{X}_{p,q}^\perp(t_0) \times \ell^p(\mathbb{Z}; \mathbb{R})$. In particular, we obtain bounds for the Green’s function viewed as a mapping

$$G(t, t_0) : \mathcal{X}_{p,q}^\perp(t_0) \times \ell^p(\mathbb{Z}; \mathbb{R}) \to \mathcal{X}_{p,q}^\perp(t) \times \ell^q(\mathbb{Z}; \mathbb{R})$$

(4.4)

with $q_1 \in \{1, 2\}$ and $q_2 \in \{2, \infty\}$.

Our first results show that any solution $(v, \theta)$ to (4.1) can in fact be seen as the coordinates of a solution $\bar{w}$ to the system

$$\frac{d}{dt} \bar{w}(t) = L_{ct} \pi^\times \bar{w}(t)$$

(4.5)

posed on $\ell^\infty(\mathbb{Z}^2; \mathbb{R}^d)$. In particular, there is a close connection between the Green’s function $\mathcal{G}(t, t_0) \in \mathcal{L}(\ell^\infty(\mathbb{Z}^2; \mathbb{R}^d))$ associated to (4.5) and the Green’s function $G(t, t_0)$ for (4.1).

**Lemma 4.1.** Suppose that (Hf), (H\Phi) and (HS1)$_p$-(HS3)$_p$ are satisfied. Consider any $v_{t_0} \in \ell^\infty(\mathbb{Z}^2; \mathbb{R}^d)$ and $\theta_{t_0} \in \ell^\infty(\mathbb{Z}; \mathbb{R})$ for which $Q_{ct0}v_{t_0} = 0 \in \ell^\infty(\mathbb{Z}; \mathbb{R})$. Then upon writing $\bar{w}(t)$ for the solution to (4.5) with the initial condition

$$\bar{w}(t_0) = v_{t_0} + \theta_{t_0} T_{ct0} \phi,$$

(4.6)

the pair

$$v(t) = [I - P_{ct}] \bar{w}(t), \quad \theta(t) = Q_{ct} \bar{w}(t)$$

(4.7)

satisfies (4.1) with

$$v(t_0) = v_{t_0}, \quad \theta(t_0) = \theta_{t_0}.$$

(4.8)

**Proof.** By construction, for any $t \geq t_0$ we have

$$v(t) = \bar{w}(t) - \theta(t) T_{ct} \phi.$$  

(4.9)

Turning first to the equation for $\theta(t)$, we compute

$$\dot{\theta}(t) = c' Q'_{ct} \bar{w}(t) + Q_{ct} \dot{\bar{w}}(t) = c' Q'_{ct} \bar{w}(t) + Q_{ct} L_{ct} \pi^\times \bar{w}(t) = c' Q'_{ct} v(t) + c \theta(t) Q'_{ct} T_{ct0} \phi + Q_{ct} L_{ct} \pi^\times v(t) + Q_{ct} L_{ct} \pi^\times \theta(t) T_{ct} \phi.$$  

(4.10)

It hence suffices to show that for every $\theta \in \ell^\infty(\mathbb{Z}; \mathbb{R})$ we have

$$c' Q'_{ct} T_{ct0} \phi + Q_{ct} L_{ct} \pi^\times \theta T_{ct0} \phi = Q_{ct} L_{ct} M_{ct} \theta^\circ.$$  

(4.11)

To see this, note that the first order terms in the Taylor expansion of (3.43) yield

$$\pi^\times \theta T_{ct0} \phi - \theta T_{ct0} \phi = M \theta^\circ.$$  

(4.12)
In particular, we have
\[ \begin{align*}
L_{ct} \pi^x \theta_{ct} \phi &= L_{ct}M \theta^o + \theta L_{ct} \tau \phi \\
&= L_{ct}M \theta^o + \theta T_{ct} \phi',
\end{align*} \]  
(4.13)
where in the last step we used the fact that $L_0 \phi = 0$. Furthermore, differentiating $Q_{ct} T_{ct} \phi = 1$ with respect to $t$, we find
\[ cQ_{ct} T_{ct} \phi + cQ_{ct} T_{ct} \phi' = 0, \]  
(4.14)
which establishes (4.11).

It remains to consider the equation satisfied by $v(t)$. A short computation yields
\[ \begin{align*}
\dot{v}(t) &= \bar{\omega}(t) - \dot{\theta}(t) T_{ct} \phi - c\theta(t) T_{ct} \phi' \\
&= L_{ct} \pi^x \bar{\omega}(t) - P_{ct} L_{ct} [\pi^x v(t) + M_{ct} \theta^o(t)] - cP_{ct} \tau v(t) - c\theta(t) T_{ct} \phi'
\end{align*} \]  
(4.15)
which together with (4.13) completes the proof. 
\[ \square \]

**Corollary 4.2.** Consider the setting of Lemma 4.1. The Green’s function associated to the linear system (4.1) can be represented as
\[ G(t, t_0) = \begin{pmatrix}
G_{v,v}(t, t_0) & G_{v,\theta}(t, t_0) & G_{\theta,v}(t, t_0) & G_{\theta,\theta}(t, t_0)
\end{pmatrix} = \begin{pmatrix}
[I - P_{ct}] \bar{G}(t, t_0) [I - P_{ct}] & [I - P_{ct}] \bar{G}(t, t_0) T_{ct} \phi \\
Q_{ct} \bar{G}(t, t_0) [I - P_{ct}] & Q_{ct} \bar{G}(t, t_0) T_{ct} \phi
\end{pmatrix}. \]  
(4.16)

In order to study the Green’s function $\bar{G}(t, t_0)$, we exploit the fact that the LDE (4.5) posed on $\mathbb{Z}^2$ decouples into a set of LDEs posed on $\mathbb{Z}$ after taking the Fourier transform in the direction perpendicular to the propagation of the wave. In particular, let us introduce for any $1 \leq q \leq \infty$ and $q \in \{1, 2, \infty\}$ the frequency space
\[ \hat{X}_{p,q} = \ell^p(\mathbb{Z}; L^q([\pi, \pi], \mathbb{R}^d)). \]  
(4.17)

For any $v \in \chi_{p,1} \cap \chi_{p,2}$ and $\theta \in \ell^1(\mathbb{Z}; \mathbb{R}) \cap \ell^2(\mathbb{Z}; \mathbb{R})$ we can now introduce the sequence $\hat{v} \in \hat{X}_{p,2}$ and the function $\hat{\theta} \in L^2([\pi, \pi], \mathbb{R})$ defined by
\[ \hat{v}_n(\omega) = \sum_{l \in \mathbb{Z}} v_{nl} e^{-il\omega}, \quad \hat{\theta}(\omega) = \sum_{l \in \mathbb{Z}} \theta_{l} e^{-il\omega}. \]  
(4.18)

In a standard fashion, these maps can be extended to maps $v \rightarrow \hat{v}$ and $\theta \rightarrow \hat{\theta}$ from $\chi_{p,2} \rightarrow \hat{X}_{p,2}$ and $\ell^2(\mathbb{Z}; \mathbb{R}) \rightarrow L^2([\pi, \pi], \mathbb{R})$ respectively that are bounded and invertible via
\[ \begin{align*}
v_{nl} &= \frac{1}{2\pi} \int_{-\pi}^{\pi} e^{il\omega} \hat{v}_n(\omega) d\omega, \quad \theta_{l} = \frac{1}{2\pi} \int_{-\pi}^{\pi} e^{il\omega} \hat{\theta}(\omega).
\end{align*} \]  
(4.19)

The following technical result gives useful bounds for frequency dependent convolution operators.

**Lemma 4.3.** Consider any set of maps $K_{\omega} : \ell^\infty(\mathbb{Z}; \mathbb{R}^d) \rightarrow \ell^\infty(\mathbb{Z}; \mathbb{R}^d)$ defined for $\omega \in [-\pi, \pi]$ that can be represented as
\[ [K_{\omega} v]_n = \sum_{n_0 \in \mathbb{Z}} [K_{\omega}]_{n,n_0} v_{n_0}. \]  
(4.20)

Suppose that there exist constants $\eta > 0$ and $\vartheta \in \mathbb{R}$ for which the bounds
\[ [K_{\omega}]_{n,n_0} \leq m(\omega) e^{-|n-n_0+\vartheta|}, \quad \omega \in [\pi, \pi] \]  
(4.21)
hold for some function \( m(\cdot) \in L^\infty([-\pi, \pi], \mathbb{R}) \). Then there exists \( C > 0 \) that depends only on \( \eta \) such that for any \( 1 \leq p \leq \infty \) and any pair \( 1 \leq q_2 \leq q_1 \leq \infty \), the map

\[
K : \hat{\mathcal{X}}_{p,q_1} \to \hat{\mathcal{X}}_{p,q_2}
\]

defined by

\[
[Kv](\omega) = K_\omega v(\omega)
\]
satisfies the estimate

\[
\|K\|_{\mathcal{L}(\hat{\mathcal{X}}_{p,q_1}, \hat{\mathcal{X}}_{p,q_2})} \leq C \|m\|_{\mathcal{L}(L^{q_1}([-\pi, \pi], \mathbb{R}), L^{q_2}([-\pi, \pi], \mathbb{R}))} \leq C \|m\|_{L^p([-\pi, \pi], \mathbb{R})},
\]

in which

\[
1 - \frac{1}{s} = \frac{1}{q_2} - \frac{1}{q_1}.
\]

Proof. Writing \( M_{q_1,q_2} = \|m\|_{\mathcal{L}(L^{q_1}([-\pi, \pi], \mathbb{R}), L^{q_2}([-\pi, \pi], \mathbb{R}))} \), the generalized Hölder’s inequality shows that

\[
M_{q_1,q_2} \leq \|m\|_{L^p([-\pi, \pi], \mathbb{R})}.
\]

Using Minkowski’s inequality, we obtain

\[
\|Kv\|_{L^{q_2}([-\pi, \pi], \mathbb{R}^d)} \leq \left[ \int_\mathbb{R} \left| \sum_{n_0 \in \mathbb{Z}} e^{-\eta |n-n_0+\delta|} \|v_{n_0}(\omega)\|^2 |m(\omega)|^{q_2} d\omega \right|^{1/q_2} \right]^{1/p} \leq \sum_{n_0 \in \mathbb{Z}} e^{-\eta |n-n_0+\delta|} \left[ \int \|v_{n_0}(\omega)\|^{q_2} |m(\omega)|^{q_2} d\omega \right]^{1/q_2} \leq \sum_{n_0 \in \mathbb{Z}} e^{-\eta |n-n_0+\delta|} M_{q_1,q_2} \|v_{n_0}(\cdot)\|_{L^{q_1}([-\pi, \pi], \mathbb{R}^d)}.
\]

If \( 1 \leq p < \infty \), an application of Young’s inequality now yields

\[
\|Kv\|_{\hat{\mathcal{X}}_{p,q_2}} \leq \left[ \sum_{n_0 \in \mathbb{Z}} e^{-\eta |n-n_0|} M_{q_1,q_2} \|v_{n_0}(\cdot)\|_{L^{q_1}([-\pi, \pi], \mathbb{R}^d)} \right]^{1/p} \leq C_1 \|v\|_{\hat{\mathcal{X}}_{p,q_1}} \leq C_2 M_{q_1,q_2} \|v\|_{\hat{\mathcal{X}}_{p,q_1}}.
\]

A simpler argument can be used for the remaining case \( p = \infty \).

Formally taking the Fourier transform of the LDE (4.5) yields the system of uncoupled LDEs

\[
\partial_t \hat{\varpi}(t, \omega) = L_{ct} \hat{\pi}^\times(t, \omega), \quad \omega \in [-\pi, \pi],
\]

in which we have introduced the map \( \hat{\pi}^\times \in \mathcal{L}(L^p(\mathbb{Z}, \mathbb{R}^d), L^p(\mathbb{Z}; (\mathbb{R}^d)^3)) \) that acts as

\[
[\hat{\pi}^\times v]_n = (e^{i\sigma_2 \omega} v_{n+\sigma_1}, e^{-i\sigma_1 \omega} v_{n+\sigma_2}, e^{-i(\sigma_2 \omega)} v_{-n-\sigma_1}, e^{i\sigma_1 \omega} v_{-n-\sigma_2}, v_n).
\]

We write \( \varpi_\omega(t, t_0) \in \mathcal{L}(L^p(\mathbb{Z}; \mathbb{R}^d)) \) for the Green’s function associated to the 1d LDE

\[
\frac{d}{dt} \hat{\varpi}(t) = L_{ct} \hat{\pi}^\times(t).
\]

The following preliminary result provides some basic information for the Green’s function \( \varpi_\omega(t, t_0) \) that allows us to show that (4.5) is well-posed as an evolution on \( \mathcal{X}_{p,2} \).

**Lemma 4.4.** Suppose that (Hf), (HΦ), (HS)_{e\nu}, (HS1)_{p}(HS3)_{p} and (HS1)_{e}(HS2)_{\omega} are all satisfied and pick any \( \epsilon > 0 \). Then the Green’s function \( \varpi_\omega(t, t_0) \) can be represented as the convolution

\[
[\varpi_\omega(t, t_0)]_n = \sum_{n_0 \in \mathbb{Z}} [\varpi_\omega(t, t_0)]_{n,n_0} \varpi_{n_0}
\]

and there exist constants \( C > 0 \) and \( \eta > 0 \) such that we have the bound

\[
[\varpi_\omega(t, t_0)]_{n,n_0} \leq C e^{(t-t_0)\epsilon^{-\eta \epsilon n + ct_0 - \epsilon Ct_0}}
\]

for every \( t \geq t_0 \) and \( \omega \in [-\pi, \pi] \).
Lemma 4.6. Let $\lambda$ be a solution to isolate the leading order dynamics of (4.31) associated to the eigenvalues $G_\omega(\xi, \xi_0, \lambda)$ which implies that the integration contour in (4.34) can be shifted to the left as long as $G_\omega(\xi, \xi_0, \lambda)$ is analytic. The construction of the functions $G_\omega(\xi, \xi_0, \lambda)$ is invertible, the map $(\lambda, \omega) \mapsto G_\omega(\xi, \xi_0, \lambda)$ is continuous and analytic in the first variable. In particular, our spectral assumptions allow us to pick $\gamma = \epsilon > 0$ for all $\omega \in [-\pi, \pi]$. The bound (4.33) follows from [20, Eq. (2.35)]. The exponent $\eta > 0$ can be chosen to be independent of $\omega$ due to the fact that the characteristic equations
\[
\det[\Delta^\pm(z) - \epsilon I] = 0
\]
have no roots in sufficiently narrow vertical strips $|\text{Re } z| \leq 2\eta$. This is a consequence of $(\text{HS})_{\text{ess}}$ together with the $a$-priori bound on $\text{Im } z$ established in [24, Lem. 3.1].

Lemma 4.5. Suppose that $(Hf)$, $(H\Phi)$, $(\text{HS})_{\text{ess}}$, $(\text{HS}1)_p$-$(\text{HS}3)_p$ and $(\text{HS}1)_o$-$(\text{HS}2)_o$ are all satisfied. Pick any $t_0 \in \mathbb{R}$ and $\overline{w}_{t_0} \in X_{p,2}$. Write $\overline{w}(t)$ for the solution to (4.5) with $\overline{w}(t_0) = \overline{w}_{t_0}$. Then for all $t \geq t_0$ we have $\overline{w}(t) \in X_{p,2}$, together with
\[
\overline{w}_{nt}(t) = \frac{1}{2\pi} \int_{-\pi}^{\pi} e^{i\omega t} \sum_{n_0 \in \mathbb{Z}} [\overline{G}_\omega(t, t_0)]_{n,n_0} [\overline{w}_{t_0}(\omega)]_{n_0} d\omega.
\]

Proof. Let us first consider $\overline{w}_{t_0} \in X_{p,1} \cap X_{p,2}$. The Fourier transform $\hat{\overline{w}}_{t_0}^*\omega$ is now well-defined for all $\omega \in [-\pi, \pi]$ and $\|\hat{\overline{w}}_{t_0}^\omega\|_{\tilde{X}_{p,\infty}} \leq \|\overline{w}_{t_0}\|_{X_{p,1}}$. Upon writing $\hat{\zeta}(t) = \overline{G}_\omega(t, t_0)\overline{w}_{t_0}(\omega)$, we see by Lemma 4.3 and Lemma 4.4 that $\zeta(t) \in \tilde{X}_{p,\infty} \subset \tilde{X}_{p,2}$ for all $t \geq t_0$. Upon writing $\hat{\tilde{w}}(t) \in X_{p,2}$ for the inverse Fourier transform of $\zeta(t)$, we find by construction that $\tilde{w}$ solves (4.5) with $\tilde{w}(t_0) = \tilde{w}_{t_0}$. By uniqueness of solutions, we now must have $\tilde{w}(t) = \tilde{w}(t)$ for all $t \geq t_0$. These conclusions can now be extended to $\overline{w}_{t_0} \in X_{p,2}$ in a standard fashion.

In light of Proposition 2.1, we can define for any $t \in \mathbb{R}$ and $\omega \in (-\delta, \delta)$ the operator
\[
Q_{\omega,ct}(\omega) \psi = \sum_{n \in \mathbb{Z}} \psi_\omega(n + ct) v_n,
\]
with the projection $P_{\omega,ct} = T_{ct} P_\omega Q_{\omega,ct}$. These frequency dependent projections can be used to isolate the leading order dynamics of (4.31) associated to the eigenvalues $\lambda_\omega$. This allows us to considerably refine the crude estimates in Lemma 4.4.

Lemma 4.6. Suppose that $(Hf)$, $(H\Phi)$, $(\text{HS})_{\text{ess}}$, $(\text{HS}1)_p$-$(\text{HS}3)_p$ and $(\text{HS}1)_o$-$(\text{HS}2)_o$ are all satisfied. Then there exist constants $\delta_\omega > 0$, $C > 0$, $\beta > 0$ and $\eta > 0$ such that for any $\omega \in [-\pi, \pi]$ with $|\omega| \geq \delta_\omega$ we have
\[
[\overline{G}_\omega(t, t_0)]_{n,n_0} \leq Ce^{-\beta(t-t_0)}e^{-\eta|n+ct-n_0-ct_0|},
\]
for any sufficiently large $\gamma \gg 1$, in which the functions $G_\omega(\xi, \xi_0, \lambda)$ solve the MFDE
\[
(L_\omega - \lambda)G_\omega(\cdot, \xi_0, \lambda) = \delta(\cdot - \xi_0)
\]
in the sense of distributions. In view of the symmetry (2.20), we see that
\[
G_\omega(\xi, \xi_0, \lambda + 2\pi ic) = e^{2\pi i(\xi_0-\xi)}G(\xi, \xi_0, \lambda),
\]
which implies that the integration contour in (4.34) can be shifted to the left as long as $G_\omega(\xi, \xi_0, \cdot)$ is analytic. The construction of the functions $G_\omega$ in [20, Lem. 2.6] shows that on regions where $L_\omega - \lambda$ is invertible, the map $(\lambda, \omega) \mapsto G_\omega(\xi, \xi_0, \lambda)$ is continuous and analytic in the first variable. The exponent $\eta > 0$ can be chosen to be independent of $\omega$ due to the fact that the characteristic equations
\[
\det[\Delta^\pm(z) - \epsilon I] = 0
\]
have no roots in sufficiently narrow vertical strips $|\text{Re } z| \leq 2\eta$. This is a consequence of $(\text{HS})_{\text{ess}}$ together with the $a$-priori bound on $\text{Im } z$ established in [24, Lem. 3.1].
while for any $\omega \in (-\delta, \delta)$ we have
\[
\overline{g}_\omega(t, t_0) = e^{-\lambda\omega(t-t_0)}T_{ct} \phi_\omega Q_{\omega,ct_0} + \overline{H}_{1,\omega}(t, t_0),
\]
(4.41)
together with the bound
\[
|\overline{H}_{1,\omega}(t, t_0)|_{n,n_0} \leq Ce^{-\beta(t-t_0)}e^{-\eta|n+ct-n_0-ct_0|}.
\]
(4.42)

\textbf{Proof.} Recall the representation (4.34) and pick a sufficiently small $\delta_\lambda > 0$. For convenience, write
\[
\Omega = \{ (\lambda, \omega) \in \mathbb{C} \times (-\delta, \delta_\omega) \mid 0 < |\lambda - \lambda_\omega| < \delta_\lambda \}.
\]
(4.43)
We can proceed as in [20, Lem. 2.7] to write
\[
G_\omega(\xi, \xi_0, \lambda) = E_\omega(\xi, \xi_0, \lambda) + H_\omega(\xi, \xi_0, \lambda)
\]
(4.44)
for all pairs $(\lambda, \omega) \in \Omega$, in which $E_\omega$ is explicitly given by
\[
E_\omega(\xi, \xi_0, \lambda) = -(\lambda - \lambda_\omega)^{-1} \phi_\omega(\xi)\psi(\xi_0)^*.
\]
(4.45)
while the remainder $(\lambda, \omega) \mapsto H_\omega(\xi, \xi_0, \lambda)$ is continuous and analytic in the first variable. In addition, we claim that for some $C > 0$ and $\eta > 0$ the uniform bound
\[
|H_\omega(\xi, \xi_0, \lambda)| \leq Ce^{-\eta|\xi-\xi_0|}
\]
(4.46)
holds for all $(\lambda, \omega) \in \Omega$. To see this, we note that the operator $L_\omega$ appearing in the proof of [20, Lem. 2.7], which in our case can be interpreted as a quasi inverse for $L_\omega - \lambda_\omega$, can be constructed in such a way that it depends continuously on $\omega$. This is a direct consequence of the fact that the direct sum decomposition [25, Eq. (4.7)] associated to $L_\omega - \lambda_\omega$ depends continuously on $\omega$ in view of Proposition 2.1.

The meromorphic expansion (4.44) allows us to shift the integration contour in (4.34) to the left of the imaginary axis, picking up the appropriate residues. Indeed, the constant $\beta > 0$ appearing in the statement comes from the fact that Propositions 2.1-2.3 imply that $L_\omega - \lambda$ is Fredholm with index zero on the half-plane $\text{Re} \lambda \geq -\beta$ and is invertible on this half plane except for the simple poles at $\lambda = \lambda_\omega$ which we have now accounted for.

From now on, we assume without loss of generality that $\sigma_1 \neq 0$, noting that this can always be realized by flipping the horizontal and vertical directions if necessary. The key is that we can write
\[
T_{ct}\phi_\omega Q_{\omega,ct_0} = T_{ct}\phi Q_{ct_0} - i\sigma_1^{-1}[e^{i\sigma_1\omega} - 1]T_{ct}[\partial_\omega \phi]_{\omega=0}Q_{ct_0} - i\sigma_1^{-1}[e^{i\sigma_1\omega} - 1]T_{ct}\phi[\partial_\omega Q_{\omega,ct_0}]_{\omega=0}
\]
(4.47)
for any $\omega \in (-\delta, \delta)$, where the $C^2$-smoothness of the branch $\omega \mapsto (\phi_\omega, \psi_\omega) \in BC_{-\eta}(\mathbb{R}, \mathbb{R}^d)^2$ allows us to estimate
\[
|[Q_{\omega}(t, t_0)]_{n,n_0}| \leq C\omega^2 e^{-\eta|n+ct-n_0-ct_0|}.
\]
(4.48)
Note that we are using $e^{i\sigma_1\omega} - 1$ to replace the regular $O(\omega)$ term in the Taylor expansion. The interpretation of the formal symbol as a difference operator in the transverse spatial direction is exploited heavily in the nonlinear argument in §5.

For any $t \geq 0$, we now introduce the function $m_t \in L^\infty([\pi, \pi], \mathbb{R})$ that is given by
\[
m_t(\omega) = \begin{cases} 
    e^{-\lambda_\omega t} & \omega \in (-\delta, \delta), \\
    0 & \omega \notin (-\delta, \delta).
\end{cases}
\]
(4.49)
Exploiting the representation (4.47) allows us to obtain the following estimate.
Corollary 4.7. Consider the setting of Lemma 4.6. There exist constants \( \delta_\omega > 0 \), \( C > 0 \), \( \beta > 0 \), \( \kappa > 0 \) and \( \eta > 0 \) such that for any \( \omega \in [-\pi, \pi] \) we may write
\[
\overline{G}_\omega(t, t_0) = m_{t-t_0}(\omega)T_{t_0}\phi Q_{t_0} - i\sigma_1^{-1}e^{i\sigma_1\omega}m_{t-t_0}(\omega)T_{t_0}\{\partial_\omega\phi\}|_{\omega=0}Q_{t_0} + i\sigma_1^{-1}e^{i\sigma_1\omega}m_{t-t_0}(\omega)T_{t_0}\phi|_{\omega=0}Q_{t_0} + \mathcal{H}_2(t, t_0),
\]
in which we have the bound
\[
\|\mathcal{H}_2(t, t_0)\|_{n, n_0} \leq C|\omega|^2e^{-\kappa\omega^2(t-t_0)} + e^{-\beta(t-t_0)}e^{-\eta|n+ct-n_0-ct_0|}.
\]

Throughout the remainder of this section, we exploit the representation (4.50) to obtain detailed bounds for the components of the Green’s function \( \mathcal{G}(t, t_0) \). We start by providing some basic preliminary estimates.

Lemma 4.8. Fix \( \kappa > 0 \) and consider the multiplication operators induced by the functions \( \tilde{m}_{k,t}(\omega) = |\omega|^k e^{-\kappa\omega^2t} \). There exists \( C > 0 \) such that the following estimates hold for all integers \( k \in \{0, 1, 2\} \).
\[
\begin{align*}
\|\tilde{m}_{k,t}\|_{L^2([-\pi, \pi], \mathbb{R})} & \leq C(1 + t)^{-k/2}, \\
\|\tilde{m}_{k,t}\|_{L^\infty([-\pi, \pi], \mathbb{R})} & \leq C(1 + t)^{-(k+1/2)}, \\
\|\tilde{m}_{k,t}\|_{L^2([-\pi, \pi], \mathbb{R})} & \leq C(1 + t)^{-k/2}, \\
\|\tilde{m}_{k,t}\|_{L^\infty([-\pi, \pi], \mathbb{R})} & \leq C(1 + t)^{-(k+1/2)}. 
\end{align*}
\]

Proof. These bounds follow from Lemma 4.3, upon estimating \( \|\tilde{m}_{k,t}\|_{L^s([-\pi, \pi], \mathbb{R})} \) with \( s = \infty \) for the first estimate, \( s = 2 \) for the second and third estimates and \( s = 1 \) for the last estimate. \( \square \)

For convenience, we write \( A(t, t_0) : \ell^2(\mathbb{Z}; \mathbb{R}) \rightarrow \ell^2(\mathbb{Z}; \mathbb{R}) \) for the Fourier multiplication operator that acts in frequency space as
\[
A(t, t_0) : \hat{\theta} \mapsto m_{t-t_0}(\omega)\hat{\theta}(\omega), \quad \omega \in [-\pi, \pi].
\]
Using the bounds
\[
\|\hat{\theta}\|_{L^\infty([-\pi, \pi], \mathbb{R})} \leq \|\theta\|_{\ell^1(\mathbb{Z}; \mathbb{R})}, \quad \|\theta\|_{\ell^\infty(\mathbb{Z}; \mathbb{R})} \leq \frac{1}{2\pi} \|\hat{\theta}\|_{L^1([-\pi, \pi], \mathbb{R})},
\]
the estimates in Lemma 4.8 with \( k = 0 \) now imply that
\[
\begin{align*}
\|A(t, t_0)\|_{\ell^2(\mathbb{Z}; \mathbb{R})} & \leq C, \\
\|A(t, t_0)\|_{\ell^1(\mathbb{Z}; \mathbb{R})} & \leq C(1 + t - t_0)^{-1/4}, \\
\|A(t, t_0)\|_{\ell^\infty(\mathbb{Z}; \mathbb{R})} & \leq C(1 + t - t_0)^{-1/4}, \\
\|A(t, t_0)\|_{\ell^1(\mathbb{Z}; \mathbb{R})} & \leq C(1 + t - t_0)^{-1/2}.
\end{align*}
\]
We also introduce the shorthand \( A^\circ(t, t_0) \) for the operator \( \theta \mapsto [A(t, t_0)\theta]^\circ = A(t, t_0)\theta^\circ \), which in view of Lemma 4.8 with \( k = 1 \) has the bounds
\[
\begin{align*}
\|A^\circ(t, t_0)\|_{\ell^2(\mathbb{Z}; \mathbb{R}^5)} & \leq C(1 + t - t_0)^{-1/2}, \\
\|A^\circ(t, t_0)\|_{\ell^1(\mathbb{Z}; \mathbb{R}^5)} & \leq C(1 + t - t_0)^{-3/4}, \\
\|A^\circ(t, t_0)\|_{\ell^\infty(\mathbb{Z}; \mathbb{R}^5)} & \leq C(1 + t - t_0)^{-3/4}, \\
\|A^\circ(t, t_0)\|_{\ell^1(\mathbb{Z}; \mathbb{R}^5)} & \leq C(1 + t - t_0)^{-1}.
\end{align*}
\]
Finally, for any unit vector $e \in \mathbb{R}^5$ we write $A^\omega(t, t_0)$ for the operator $\theta \mapsto [e \cdot A^\omega(t, t_0)\theta]^\omega$, which in view of Lemma 4.8 with $k = 2$ has the bounds
\[
\|A^\omega(t, t_0)\|_{\ell^2(\mathbb{Z}; \mathbb{R}) \to \ell^2(\mathbb{Z}; \mathbb{R}^5)} \leq C(1 + t - t_0)^{-1},
\|A^\omega(t, t_0)\|_{\ell^2(\mathbb{Z}; \mathbb{R}) \to \ell^2(\mathbb{Z}; \mathbb{R}^5)} \leq C(1 + t - t_0)^{-5/4},
\|A^\omega(t, t_0)\|_{\ell^2(\mathbb{Z}; \mathbb{R}) \to \ell^\infty(\mathbb{Z}; \mathbb{R}^5)} \leq C(1 + t - t_0)^{-5/4},
\|A^\omega(t, t_0)\|_{\ell^2(\mathbb{Z}; \mathbb{R}) \to \ell^\infty(\mathbb{Z}; \mathbb{R}^5)} \leq C(1 + t - t_0)^{-3/2}.
\]

We now obtain the following estimates on the Green’s function $G(t, t_0)$ and the associated operators $G^\omega(t, t_0)$ that are defined by
\[
G^\omega(t, t_0) \left( \frac{v}{\theta} \right) = \left[ G(t, t_0) \left( \frac{v}{\theta} \right) \right]^\omega.
\]

**Proposition 4.9.** Suppose that $(Hf)$, $(H\Phi)$, $(HS)_{\text{ass}}, (HS1)_{p, \omega}$, $(HS2)_{p, \omega}$, and $(HS1)_{p, \omega}$, $(HS2)_{\omega}$ are all satisfied. Pick any $1 \leq p \leq \infty$ and introduce the shorthand
\[
\chi_{ct} = -i[t - P_{ct}]T_{ct}[\partial_{\nu}\phi]_{\omega = 0}.
\]

Then there exists $C > 0$ such that for any $t \geq t_0$, the Green’s function $G(t, t_0)$ for (4.1) satisfies the bounds
\[
\|G_{\nu v}(t, t_0)\|_{\ell^2(\mathbb{Z}; \mathbb{R}) \to \ell^2(\mathbb{Z}; \mathbb{R}^5)} \leq C(1 + t - t_0)^{-1},
\|G_{\nu v}(t, t_0)\|_{\ell^2(\mathbb{Z}; \mathbb{R}) \to \ell^2(\mathbb{Z}; \mathbb{R}^5)} \leq C(1 + t - t_0)^{-5/4},
\|G_{\nu v}(t, t_0)\|_{\ell^2(\mathbb{Z}; \mathbb{R}) \to \ell^\infty(\mathbb{Z}; \mathbb{R}^5)} \leq C(1 + t - t_0)^{-5/4},
\|G_{\nu v}(t, t_0)\|_{\ell^2(\mathbb{Z}; \mathbb{R}) \to \ell^\infty(\mathbb{Z}; \mathbb{R}^5)} \leq C(1 + t - t_0)^{-3/2},
\]
in which $e_4 = (0, 0, 0, 1, 0)$, together with
\[
\|G_{\nu v}(t, t_0)\|_{\ell^2(\mathbb{Z}; \mathbb{R}) \to \ell^2(\mathbb{Z}; \mathbb{R}^5)} \leq C(1 + t - t_0)^{-1/2},
\|G_{\nu v}(t, t_0)\|_{\ell^2(\mathbb{Z}; \mathbb{R}) \to \ell^2(\mathbb{Z}; \mathbb{R}^5)} \leq C(1 + t - t_0)^{-3/4},
\|G_{\nu v}(t, t_0)\|_{\ell^2(\mathbb{Z}; \mathbb{R}) \to \ell^\infty(\mathbb{Z}; \mathbb{R}^5)} \leq C(1 + t - t_0)^{-3/4},
\|G_{\nu v}(t, t_0)\|_{\ell^2(\mathbb{Z}; \mathbb{R}) \to \ell^\infty(\mathbb{Z}; \mathbb{R}^5)} \leq C(1 + t - t_0)^{-1}.
\]

In addition, for any $t \geq t_0$ the components of the function $G^\omega(t, t_0)$ have the bounds
\[
\|G^\omega_{\nu v}(t, t_0)\|_{\ell^2(\mathbb{Z}; \mathbb{R}) \to \ell^2(\mathbb{Z}; \mathbb{R}^5)} \leq C(1 + t - t_0)^{-1},
\|G^\omega_{\nu v}(t, t_0)\|_{\ell^2(\mathbb{Z}; \mathbb{R}) \to \ell^2(\mathbb{Z}; \mathbb{R}^5)} \leq C(1 + t - t_0)^{-5/4},
\|G^\omega_{\nu v}(t, t_0)\|_{\ell^2(\mathbb{Z}; \mathbb{R}) \to \ell^\infty(\mathbb{Z}; \mathbb{R}^5)} \leq C(1 + t - t_0)^{-5/4},
\|G^\omega_{\nu v}(t, t_0)\|_{\ell^2(\mathbb{Z}; \mathbb{R}) \to \ell^\infty(\mathbb{Z}; \mathbb{R}^5)} \leq C(1 + t - t_0)^{-3/2},
\]

otherwise with
\[
\|G^\omega_{\nu v}(t, t_0)\|_{\ell^2(\mathbb{Z}; \mathbb{R}) \to \ell^2(\mathbb{Z}; \mathbb{R}^5)} \leq C(1 + t - t_0)^{-1},
\|G^\omega_{\nu v}(t, t_0)\|_{\ell^2(\mathbb{Z}; \mathbb{R}) \to \ell^2(\mathbb{Z}; \mathbb{R}^5)} \leq C(1 + t - t_0)^{-5/4},
\|G^\omega_{\nu v}(t, t_0)\|_{\ell^2(\mathbb{Z}; \mathbb{R}) \to \ell^\infty(\mathbb{Z}; \mathbb{R}^5)} \leq C(1 + t - t_0)^{-5/4},
\|G^\omega_{\nu v}(t, t_0)\|_{\ell^2(\mathbb{Z}; \mathbb{R}) \to \ell^\infty(\mathbb{Z}; \mathbb{R}^5)} \leq C(1 + t - t_0)^{-3/2}.
\]
Proof. In view of the representation of $G(t, t_0)$ given in Corollary 4.2, the bounds above can be derived from the expressions for $G_w(t, t_0)$ given in Corollary 4.7. To this end, one can use the estimates in Lemma’s 4.3 and 4.8, together with the facts that $Q_cT_c\Phi = 1$, that $[I - P_c]T_cQ_c = 0$ and that $Q_{ct_0}v_{t_0} = 0$.

In the sequel, it is convenient to decompose the function $v(t)$ as

$$v(t) = w(t) + \chi_{ct_0}^{-1}e_4 \cdot \theta^\circ(t).$$

As a direct consequence of Proposition 4.9 we can now obtain the following bounds for the linear evolution of $w(t)$.

**Corollary 4.10.** Consider the setting of Proposition 4.9. Upon writing

$$G_w(t, t_0) = (G_{w^1}(t, t_0) \quad G_{w^2}(t, t_0))$$

for the $1 \times 2$ operator valued matrix with components

$$G_{w^1}(t, t_0) := G_{w^1}(t, t_0) - \chi_{ct_0}^{-1}e_4 \cdot G_{\theta^\circ}(t, t_0),$$

$$G_{w^2}(t, t_0) := G_{w^2}(t, t_0) - \chi_{ct_0}^{-1}e_4 \cdot G_{\theta^\circ}(t, t_0),$$

there exists $C > 0$ such that the following estimates hold for all $t \geq t_0$,

$$\|G_{w^1}(t, t_0)\|_{X^1 \rightarrow X^2} + \|G_{w^2}(t, t_0)\|_{l^2(Z; \mathbb{R}) \rightarrow X^1} \leq C(1 + t - t_0)^{-1},$$

$$\|G_{w^1}(t, t_0)\|_{X^1 \rightarrow X^2} + \|G_{w^2}(t, t_0)\|_{l^1(Z; \mathbb{R}) \rightarrow X^1} \leq C(1 + t - t_0)^{-5/4},$$

$$\|G_{w^1}(t, t_0)\|_{X^1 \rightarrow X^2} + \|G_{w^2}(t, t_0)\|_{l^2(Z; \mathbb{R}) \rightarrow X^1} \leq C(1 + t - t_0)^{-5/4},$$

$$\|G_{w^1}(t, t_0)\|_{X^1 \rightarrow X^2} + \|G_{w^2}(t, t_0)\|_{l^1(Z; \mathbb{R}) \rightarrow X^1} \leq C(1 + t - t_0)^{-3/2}.$$ (4.67)

### 5 Proof of Main Results

In this section we set up the nonlinear iteration argument that is used to prove our main results. In particular, we fix $1 \leq p \leq \infty$, pick an initial condition

$$v_0 \in X^1_{p,1}(0), \quad \theta_0 \in l^1(Z; \mathbb{R})$$

and consider for $t \geq 0$ the fixed point problem

$$
\begin{pmatrix}
v(t) \\
\theta(t)
\end{pmatrix}
= G(t, 0)
\begin{pmatrix}
v_0 \\
\theta_0
\end{pmatrix}
+ \int_0^t G(t, t_0)
\begin{pmatrix}
0 \\
\theta(t_0)H_4[\tau v(t_0), \theta^\circ(t_0)]
\end{pmatrix}
dt_0
+ \int_0^t G(t, t_0)
\begin{pmatrix}
R_{4,ct_0}(v(t_0), \theta(t_0)) \\
S_{4,ct_0}(v(t_0), \theta(t_0))
\end{pmatrix}
dt_0.
$$

(5.2)

Upon writing

$$w(t) = v(t) - \chi_{ct_0}^{-1}e_4 \cdot \theta^\circ(t),$$

we observe by linearity that any solution to (5.2) for some $t \geq 0$ necessarily satisfies the system

$$
\begin{pmatrix}
v^\circ(t) \\
\theta^\circ(t) \\
w(t)
\end{pmatrix}
= \begin{pmatrix}
G^\circ(t, 0) \\
G_{w^1}(t, t_0) \\
G_{w^2}(t, t_0)
\end{pmatrix}
\begin{pmatrix}
v_0 \\
\theta_0 \\
\theta(t_0)
\end{pmatrix}
+ \int_0^t \begin{pmatrix}
G^\circ(t, t_0) \\
G_{w^1}(t, t_0) \\
G_{w^2}(t, t_0)
\end{pmatrix}
\begin{pmatrix}
0 \\
\theta(t_0)H_4[\tau v(t_0), \theta^\circ(t_0)] \\
R_{4,ct_0}(v(t_0), \theta(t_0)) \\
S_{4,ct_0}(v(t_0), \theta(t_0))
\end{pmatrix}
dt_0
+ \int_0^t \begin{pmatrix}
G^\circ(t, t_0) \\
G_{w^1}(t, t_0) \\
G_{w^2}(t, t_0)
\end{pmatrix}
\begin{pmatrix}
R_{4,ct_0}(v(t_0), \theta(t_0)) \\
S_{4,ct_0}(v(t_0), \theta(t_0))
\end{pmatrix}
dt_0.
$$

(5.4)
We write
\[ E_0 = \|v_0\|_{X_{p,1}} + \|\theta_0\|_{L^1(\mathbb{Z}; \mathbb{R})}. \]  
Eq. (5.5)

We also introduce the non-decreasing functions
\[
\begin{align*}
M_v(t) &= \sup_{0 \leq t \leq t} (1 + t_0) \|v(t_0)\|_{X_{p,2}}, \\
M_v(t) &= \sup_{0 \leq t \leq t} (1 + t_0) \|v(t_0)\|_{X_{p,\infty}}, \\
M_v(t) &= \sup_{0 \leq t \leq t} (1 + t_0)^{3/4} \|v(t_0)\|_{X_{p,2}}, \\
M_v(t) &= \sup_{0 \leq t \leq t} (1 + t_0)^{5/4} \|v(t_0)\|_{X_{p,\infty}},
\end{align*}
\]
Eq. (5.6)

together with
\[
\begin{align*}
M_\theta(t) &= \sup_{0 \leq t \leq t} (1 + t_0)^{1/4} \|\theta(t_0)\|_{\ell^2(\mathbb{Z}; \mathbb{R})}, \\
M_\theta(t) &= \sup_{0 \leq t \leq t} (1 + t_0)^{1/2} \|\theta(t_0)\|_{\ell^\infty(\mathbb{Z}; \mathbb{R})}, \\
M_\theta(t) &= \sup_{0 \leq t \leq t} (1 + t_0)^{3/4} \|\theta(t_0)\|_{\ell^2(\mathbb{Z}; \mathbb{R})}, \\
M_\theta(t) &= \sup_{0 \leq t \leq t} (1 + t_0)^{5/4} \|\theta(t_0)\|_{\ell^\infty(\mathbb{Z}; \mathbb{R})},
\end{align*}
\]
Eq. (5.7)

and
\[
\begin{align*}
M_w(t) &= \sup_{0 \leq t \leq t} (1 + t_0)^{9/8} \|w(t_0)\|_{X_{p,2}}, \\
M_w(t) &= \sup_{0 \leq t \leq t} (1 + t_0)^{5/4} \|w(t_0)\|_{X_{p,\infty}}.
\end{align*}
\]
Eq. (5.8)

Finally, we write
\[ M(t) = M_v(t) + M_v(t) + M_v(t) + M_v(t) + M_\theta(t) + M_\theta(t) + M_\theta(t) + M_\theta(t). \]
Eq. (5.9)

**Proposition 5.1.** Suppose that \( (Hf), (Hf), (HS)_{\text{est}}, (HS1)_p, (HS3)_p \) and \((HS1)_{\omega}(HS2)_{\omega} \) are all satisfied and pick any \( 1 \leq p \leq \infty \). Then there exists a constant \( C > 0 \) such that the following holds true. Consider any initial condition \( (v_0, \theta_0) \in X_{p,1}(0) \times \ell^1(\mathbb{Z}; \mathbb{R}) \) and suppose that for some \( T \geq 0 \) the functions
\[ v : [0, T] \to X_{p,2}, \quad \theta : [0, T] \to \ell^2(\mathbb{Z}; \mathbb{R}) \]
Eq. (5.10)
satisfy the fixed point problem (5.2) for all \( 0 \leq t \leq T \). Then the functions \( (v, \theta) \) satisfy the nonlinear LDE (3.69) for all \( 0 \leq t \leq T \) and we have the bound
\[ M(T) \leq CE_0 + CM^2(T) + CM^3(T). \]
Eq. (5.11)

In addition, for all sufficiently small \( \epsilon > 0 \) there exist functions
\[ \bar{v} : [0, T + \epsilon] \to X_{p,2}, \quad \bar{\theta} : [0, T + \epsilon] \to \ell^2(\mathbb{Z}; \mathbb{R}) \]
Eq. (5.12)

that satisfy the fixed point problem (5.2) for all \( 0 \leq t \leq T + \epsilon \) and have \( \bar{v}(t) = v(t) \) and \( \bar{\theta}(t) = \theta(t) \) for all \( 0 \leq t \leq T \).

Notice that the exponents \( 9/8 \) and \( 5/4 \) appearing in \( M_v(t) \) and \( M_w(t) \) are slightly less than the exponents \( 5/4 \) and \( 3/2 \) that one would expect from the linear evolution of the corresponding variables. This is related to the fact that, even if we assume \emph{a priori} that \( M(t) \) is bounded, the nonlinear term \( R_{4,\epsilon,t_0} (v(t_0), \theta(t_0)) \) decays at a rate of \( O(t_0^{-1}) \) in \( X_{p,1} \) and \( O(t_0^{-5/4}) \) in \( X_{p,2} \). These rates are typically too slow to close a nonlinear estimate. The same is true of the term \( \theta(t_0)H_{4,\epsilon,t}[\tau v(t_0), \theta^2 v(t_0)] \), which also decays at a rate of \( O(t_0^{-1}) \) in \( \ell^1(\mathbb{Z}; \mathbb{R}) \). The key is that we will exploit the special structure of
Similarly, using $\delta M$ nonlinear term for $t$ decay rapidly. By using a fast estimate on the semigroup for have to choose whether to make the semigroup decay rapidly or whether to make the nonlinear term decay more rapidly and the other decay more slowly. The point of this lemma is that you don’t the term and how good an estimate one can use on the nonlinear term. In one case we have a given a fixed DuHamel term, there is a tradeoff between how good an estimate one can use on the estimate terms on the right hand side of the variation of constants formula. It is often the case that conservation laws. The slow decay of $H$ Lemma 5.2. Consider the setting of Proposition 5.1. For any $\gamma \neq 1$ and $\delta \neq 1$. Then there is a constant $C > 0$ such that\[ \int_0^{t/2} (1 + t - t_0)^{-\alpha} (1 + t_0)^{-\gamma} dt_0 + \int_{t/2}^t (1 + t - t_0)^{-\delta} (1 + t_0)^{-\beta} dt_0 \leq C (1 + t)^{-\min\{\alpha + \gamma - 1, \beta + \delta - 1, \alpha, \beta\}}. \]Lemma 5.3 (Lemma 3.2 in [12] (restated)). Let $\alpha, \beta, \gamma$ and $\delta$ be positive real numbers, with $\gamma \neq 1$ and $\delta \neq 1$. Then there is a constant $C > 0$ such that\[ \int_0^{t/2} (1 + t - t_0)^{-\alpha} (1 + t_0)^{-\gamma} dt_0 + \int_{t/2}^t (1 + t - t_0)^{-\delta} (1 + t_0)^{-\beta} dt_0 \leq C (1 + t)^{-\min\{\alpha + \gamma - 1, \beta + \delta - 1, \alpha, \beta\}}. \]
It hence remains to consider the terms \( G \) associated to the terms \( M \) larger than the decay rate of the relevant component of appearing in (5.2) and (5.4) can be bounded as desired. The same holds true for the part of \( M \) critical case \( \gamma \). Indeed, the critical case \( \gamma = 1 \) occurs in (5.22) only when coupling \( R_4 \) with \( G_\text{vv}, G_\text{θv}, G_\text{vv}^\ast, \) and \( G_\text{ww} \), which all have \( 1 \to q \) decay rates \( \alpha \) that are faster than those of \( M_\text{v,q}, M_\text{θ,q}, M_\text{v*,q}, M_\text{θ*,q} \) and \( M_\text{w,q} \) respectively. Similarly, the semigroups \( G_\text{vθ} \) and \( G_\text{wθ} \) appearing in (5.24) have \( 1 \to q \) decay rates \( \alpha \) that are faster than those of \( M_\text{v*,q} \) and \( M_\text{w,q} \) respectively. Finally, only \( M_\text{w,**} \) and \( M_\text{w,**} \) feature the exponent \( 2 \). Since \( \beta \geq \frac{5}{2} \) and the \( 2 \to \infty \) norms of \( G_\text{vv}^\ast, G_\text{vθ}^\ast, G_\text{ww} \) and \( G_\text{wθ}^\ast \) all have \( \delta = \frac{5}{2} \), the critical case \( \delta = 1 \) occurs only when the decay rate \( \beta \) of the \( \| \cdot \|_2 \) norm of the nonlinearity is strictly larger than the decay rate of the relevant component of \( M(t) \).

The exact same arguments can also be applied for the components of \( M(t) \) associated to the terms

\[
\int_0^t \begin{pmatrix}
G_\text{vv}(t,t_0) & G_\text{vθ}(t,t_0) - \chi_{ct}\sigma_1^{-1}e_4 \cdot A^\ast(t,t_0) \\
G_\text{θv}(t,t_0) & G_\text{θθ}(t,t_0) - \chi_{ct}\sigma_1^{-1}e_4 \cdot \theta^\ast(t_0)
\end{pmatrix} dt_0.
\]

It hence remains to consider the terms

\[
\int_0^t \begin{pmatrix} 0 & \chi_{ct}\sigma_1^{-1}e_4 \cdot A^\ast(t,t_0) \\
0 & \chi_{ct}\sigma_1^{-1}e_4 \cdot A^\ast(t,t_0)
\end{pmatrix} dt_0.
\]

These components require a more refined analysis and are discussed in our next result.

---

3 Note that there is some overlap between the terms appearing in (5.22) and (5.23).
Lemma 5.5. Consider the setting of Proposition 5.1. There exists a constant \( C > 0 \) such that for any unit vector \( e \in \mathbb{R}^b \) and \( t \geq 0 \), the quantities

\[
I_q(t) := \int_0^t \|A(t, t_0)\theta(t_0)\theta^e(t_0)\|_{L^p(\mathbb{R}^b)} \, dt_0,
\]

\[
I_{q,e}(t) := \int_0^t \|A^e(t, t_0)e \cdot \theta(t_0)\theta^e(t_0)\|_{L^p(\mathbb{R}^b)} \, dt_0
\]

satisfy the estimates

\[
I_q(t) \leq CM^2(t)(1 + t)^{-1/4},
\]

\[
I_{q,e}(t) \leq CM^2(t)(1 + t)^{-1/2},
\]

\[
I_{q,e}(t) \leq CM^2(t)(1 + t)^{-3/4},
\]

\[
I_{q,e}(t) \leq CM^2(t)(1 + t)^{-1}.
\]

Proof. Restricting ourselves for the moment to \( I_q(t) \), we make use of (5.16) with exponents given by the following table.

| \( I_q \) | \( I_{q,e} \) |
|---|---|
| \( \alpha_a \) | \( \|A(t, t_0)\|_{L^1 \to L^2} \sim (t - t_0 + 1)^{-1/4} \) | \( \|A(t, t_0)\|_{L^1 \to L^\infty} \sim (t - t_0 + 1)^{-1/2} \) |
| \( \gamma_a \) | \( \|\theta^e(t_0)\|_{L^2}^2 \sim M(t)^2\| (t_0 + 1)^{-3/2} \) | \( \|\theta^e(t_0)\|_{L^2}^2 \sim M(t)^2\| (t_0 + 1)^{-3/2} \) |
| \( \alpha_b \) | \( \|A^e(t, t_0)\|_{L^1 \to L^2} \sim (t - t_0 + 1)^{-3/4} \) | \( \|A^e(t, t_0)\|_{L^1 \to L^\infty} \sim (t - t_0 + 1)^{-1} \) |
| \( \gamma_b \) | \( \|\theta(t_0)\|_{L^2}^2 \sim M(t)^2\| (t_0 + 1)^{-1/2} \) | \( \|\theta(t_0)\|_{L^2}^2 \sim M(t)^2\| (t_0 + 1)^{-1/2} \) |
| \( \delta \) | \( \|A(t, t_0)\|_{L^1 \to L^2} \sim C \) | \( \|A(t, t_0)\|_{L^1 \to L^\infty} \sim (t - t_0 + 1)^{-1/4} \) |
| \( \beta \) | \( \|\theta^e\|_{L^\infty} \|\theta\|_{L^2} \sim M(t)^2\| (t - t_0 + 1)^{-5/4} \) | \( \|\theta^e\|_{L^\infty} \|\theta\|_{L^2} \sim M(t)^2\| (t - t_0 + 1)^{-5/4} \) |

The last two rows are straightforward to understand. This corresponds to the time interval \([t/2, t]\) on which the semigroup is weak regardless of its rate of decay and the accumulation of the nonlinear terms is what is dangerous. Our nonlinear terms \( \|\theta^e\|_{L^1} \|\theta\|_{L^2} \) decay so rapidly that we can use even the incredibly weak \( L^2 \to L^1 \) estimates for \( A \). This is because the exponent \( \delta \) describing the decay of \( A \) appears on the right hand side of (5.16) only in the form \( \beta + \delta - 1 \) and never by itself, thus a large \( \beta \) can compensate for a small \( \delta \). In our case we have \( \beta + \delta - 1 = 1/4 \) for \( q = 2 \) and \( 1/2 \) for \( q = \infty \), enough to establish the desired rates of decay for \( I_q \), as long as the \([0, t/2]\) intervals cooperate.

The interval \([0, t/2]\) is more subtle. As per (1.26) we decompose the nonlinear term \( \theta^e \) into the sum of an \((a)\) term, \( (\theta^e)^2 \) (where we are interpreting the square of a vector to be the vector of the squares of the components) and a \((b)\) term \( (\theta^e)^\gamma \). The first of these we estimate in the usual way using the \( L^1 \to L^2 \) norm on the semigroup. For the second of these, we make use of the definition of \( A^\alpha \) to transfer the \( \alpha \) from \( \theta^2 \) to \( A \), effectively summing by parts.

To establish the estimates for \( I_{q,e} \), simply replace \( A \) everywhere by \( A^e \) and \( A^e \) by \( A^e_{\infty} \), adding \( 1/2 \) to all values of \( \alpha \) and \( \delta \). Notice that the critical situations \( \gamma = 1 \) and \( \delta = 1 \) are never encountered. \( \square \)

Proof of Proposition 5.1. The fact that solutions to the fixed point problem (5.2) are solutions to the LDE follows from direct differentiation and the linear well-posedness result Lemma 4.5. The short term existence claims involving the constant \( \epsilon > 0 \) can be established in a standard fashion by applying the contraction mapping principle. Finally, the bound (5.11) has been verified by the discussion above. \( \square \)

Proof of Theorem 2.4. In view of the bound (5.11), one sees that whenever \( E_0 \) is sufficiently small the inequality \( M(T) \leq 3CE_0 \) must hold. In particular, if \( E_0 \) is sufficiently small it is possible to construct a solution to the fixed point problem (5.2) that is defined for all \( t \geq 0 \) by repeatedly applying Proposition 5.1. The bounds for \( \theta_{\text{diff}} \) stated in item (iii) can be established in the same
way as the bounds for \( \theta^\circ(t) \). The remainder of the decay rates given in the statement of the theorem follow directly from the definition of \( M(t) \).

Proof of Theorem 2.5. Upon writing

\[
\theta^\circ(t) = (\theta_{i+\sigma_1} + \theta_{i-\sigma_1} - 2\theta_i, \theta_{i+\sigma_2} + \theta_{i-\sigma_2} - 2\theta_i, 0),
\]

(5.28)

the estimates for the nonlinearities \( R_{4,ct} \) and \( S_{4,ct} \) that appear in Proposition 3.1 remain valid upon replacing all occurrences of \( \|\theta\| \|\theta^\circ\| \) by \( \|\theta\| \|\theta^\circ\| \). In addition, there exists an operator \( H_{5,ct} \) such that \( \theta H_{4,ct}[0, \theta^\circ] = \theta H_{5,ct} \theta^\circ \). Finally, we have \( [\partial_\omega \phi_\omega]_{\omega=0} = 0 \) and \( [\partial_\omega \psi_\omega]_{\omega=0} = 0 \), which means that \( v(t) = w(t) \). In particular, upon writing

\[
M_{\theta^\circ,2}(t) = \sup_{0 \leq t_0 \leq t} (1 + t_0)^{5/4} \|\theta^\circ(t_0)\|_{L^2(\mathbb{Z}; \mathbb{R}^3)},
\]

\[
M_{\theta^\infty,\infty}(t) = \sup_{0 \leq t_0 \leq t} (1 + t_0)^{3/2} \|\theta^\infty(t_0)\|_{L^\infty(\mathbb{Z}; \mathbb{R}^3)}
\]

(5.29)

and replacing all references to \( M_{v,0} \) by \( M_{\theta^\infty,q} \), all the nonlinear terms that decay at the rate \( O(t_0^{-1}) \) have disappeared. This allows us to replace the exponent 9/8 appearing in the definition of \( M_{w,2} \) by 5/4 and the exponent 5/4 appearing in the definition of \( M_{w,\infty} \) by 3/2.

With these choices, all the nonlinearities decay at a rate of \( O(t_0^{-3/2}) \) in \( L^1(Z; \mathbb{R}) \) or \( X_{p,1} \) and \( O(t_0^{-7/4}) \) in \( L^2(Z; \mathbb{R}) \) or \( X_{p,2} \). This is sufficiently fast to close the nonlinear argument with direct crude estimates.

Proof of Theorem 2.6. The claims concerning the triplets \( (\lambda_\omega, \phi_\omega, \psi_\omega) \) follow directly upon inspection of (2.14), which shows that

\[
L_\omega p = L_0 p + 2\kappa (\cos(\omega) - 1)p.
\]

(5.30)

This in turn implies \( \lambda_\omega = 2\kappa (\cos(\omega) - 1) \), \( \phi_\omega = \phi \) and \( \psi_\omega = \psi \), which immediately establishes the two conditions (HS1)_\omega and (HS2)_\omega. Corollary 4.2 now implies that both \( G_{vv}(t, t_0) \) and \( G_{v\theta}(t, t_0) \) decay exponentially instead of algebraically. As above in the proof of Theorem 2.5, the nonlinearities decay at a rate of \( O(t_0^{-7/4}) \) in \( L^2(Z; \mathbb{R}) \) or \( X_{p,2} \). Since these nonlinear decay rates are now the only restriction on the decay of \( w \), we can replace both of the exponents 9/8 and 5/4 appearing in the definitions of \( M_{w,2} \) and \( M_{w,\infty} \) respectively by 7/4.

\[\square\]

6 The Nagumo Equation

We return now to the scalar equation (1.1) which was discussed in the introduction. The goal of this section is twofold: firstly we show that the main theorems are not vacuous by exhibiting an example to which they apply; and secondly we present numerical studies which highlight the sensitive nature of anisotropy in the problem.

We again write

\[
\dot{u}_{ij}(t) = [\Delta^+ u(t)]_{ij} + g(u_{ij}(t); \rho),
\]

(6.1)

in which the nonlinearity \( g \) is given by

\[
g(u; \rho) = -\frac{5}{2} (u^2 - 1)(u - \rho),
\]

(6.2)

with \( \rho \in (-1, 1) \). The parameter \( \rho \) determines the location of the middle zero of the cubic and can be regarded as a measure of the difference in the depth of the wells of the potential \( G(u) = \int g(u)du \). When \( \rho \) is far from zero, the “local free energy” of the equilibria at \( \pm 1 \) are significantly different and hence the more energetically favorable equilibrium invades the spatial domain rapidly. In such a parameter regime, the lattice discreteness is hardly felt; phenomenologically (1.1) behaves very
Fig. 1: Left: plot depicting \( M_p(\theta) = -[\delta^2 \lambda_\omega]_{\omega=0} \) evaluated for (6.1) with detuning parameter \( \rho \) and direction of propagation \( (\sigma_1, \sigma_2) = (\cos \theta, \sin \theta) \). It is a polar plot, so actually plotted are \( (\cos \theta M_p(\theta), \sin \theta M_p(\theta)) \). The computations were performed with \( \gamma = 10^{-5} \). Right: \( c(\rho) \) plot for the fixed direction \( \theta = 0 \), which corresponds to \( (\sigma_1, \sigma_2) = (1, 0) \). The critical value for \( \rho \) at which pinning sets in is given. The computations were performed with \( \gamma = 10^{-6} \).

much like its PDE limit. However, when \( \rho \) is close to zero, the two equilibria are comparably stable, the more stable of the two invades the spatial domain slowly, and the lattice discreteness is felt keenly. Here we take care to retain the \( \rho \) dependence so that we can contrast the small and order 1 parameter regimes. Let \( \rho_* = \rho_*(\sigma) \) denote the largest value of \( \rho \) for which the wave is pinned (\( c = 0 \)).

We now verify the hypotheses. As a preliminary step, we state a comparison principle for the linearization of (1.1) about its traveling wave, represented in \( (n, l) \) coordinates as

\[
\dot{v}_{nl} - \{v_{n+\sigma_1,l-\sigma_2} + v_{n-\sigma_1,l+\sigma_2} + v_{n+\sigma_2,l+\sigma_1} + v_n - v_{n-\sigma_2,l-\sigma_1} - 4v_{nl} + g'(\Phi(n + ct))v_{nl}\} = 0. \tag{6.3}
\]

In case the equality in (6.3) is replaced with the inequality \( \geq (\leq) \) we say that \( v \) is a super- (sub-) solution. We make use of the following standard comparison principle.

**Lemma 6.1.** Let \( \Lambda \subset \mathbb{Z}^2 \) denote the lattice spanned by \( (\sigma_1, \sigma_2) \) and \( (\sigma_1, -\sigma_2) \) on which (6.3) is naturally posed. Let \( q^0, r^0 \in C^\infty(\Lambda, \mathbb{R}) \) with \( q^0_{nl} \geq r^0_{nl} \) for all \( (n, l) \in \Lambda \) and \( q^0 \neq r^0 \). Let \( q(t) \) and \( r(t) \) denote super- and sub-solutions to (6.3) with initial conditions \( q^0 \) and \( r^0 \) respectively. Then \( q_{nl}(t) \geq r_{nl}(t) \) for all \( t > 0 \). Moreover, if \( q \) and \( r \) are both true solutions, then the inequality is strict, i.e. \( q_{nl}(t) > r_{nl}(t) \) for all \( t > 0 \).

We now verify our main hypotheses.

**Lemma 6.2.** Consider the model equation (1.1) with nonlinearity \( g = g(\cdot; \rho) \) given by (6.2). Let \( \sigma \in \mathbb{Z}^2 \) and let \( \rho > \rho_*(\sigma) \). Then the hypotheses \( (Hf), (H\Phi), (HS1)_p, (HS2)_p, (HS3)_p, (HS)_{ess} \) and \( (HS2)_w \) all hold.

**Proof.** In the context of our abstract framework (2.1) we have \( f(u) = f(u; \rho) \) with

\[
f(u_1, u_2, u_3, u_4, u_5; \rho) = u_1 + u_2 + u_3 + u_4 + g(u_5; \rho),
\]

which is clearly \( C^2 \) and vanishes when all of the \( u_m \) are equal to \( u_{\pm} \in \{-1, 0, 1\} \). Thus \( (Hf) \) is satisfied. The notion of \( \rho_* \) along with the existence of a smooth wave profile connecting \(-1\) and \( 1 \) for arbitrary (even irrational) directions for \( \rho > \rho_* \) has been established in [29], hence \( (H\Phi) \) is satisfied as well. To verify \( (HS)_{ess} \) we compute

\[
\Delta^\pm_\omega(iv) - \lambda = -civ + 2\cos(\nu\sigma_1 + \omega\sigma_2) + 2\cos(\nu\sigma_2 - \omega\sigma_1) - 4 + g'(u_{\pm}) - \lambda. \tag{6.4}
\]
Since \( g'(u) < 0 \) and since the negative constant \(-4\) dominates the cosine terms, it follows that \( \text{Re} \lambda < 0 \) whenever (6.4) vanishes, establishing (HS)\( _{\text{ess}} \). The hypotheses (HS)\(_2\) and (HS)\(_3\) follow from [30, Thm. C] in which the positive function \( \phi \) is shown to be the principal eigenvector (in the sense of Krein-Rutman) for the positive operator \( (L_0 - \lambda)^{-1} \) when \( \lambda \) is real and large. Moreover if \( \alpha + i\beta \) is an eigenvalue of \( L_0 \), then \((\alpha + i\beta - \lambda)^{-1}\) is an eigenvalue of \( (L_0 - \lambda)^{-1} \), which necessarily has spectral radius equal to its principal eigenvalue \( \lambda^{-1} \). Taking \( \lambda \to \infty \) in the inequality \(|(\alpha + i\beta - \lambda)^{-1}| < \lambda^{-1}\) gives the inequality \( \alpha \leq 0 \), thus (HS)\(_1\) is established for eigenvalues with positive real parts.

To finish verifying (HS)\(_1\) it suffices to show, due to the \( 2\pi \text{i}c\)-periodicity of the spectrum, that with the exception of zero, \( L_0 \) has no eigenvalues on the imaginary axis.

Suppose that \( w \) is an eigenvector of \( L_0 \) with eigenvalue \( iv \). We will show that \( v \) is necessarily zero by showing that the eigensolution initially lies below the neutral mode \( \phi \), yet touches it at some positive time, implying via Lemma 6.1 that the eigensolution is the neutral mode and hence that \( \nu = 0 \).

First note that the Fredholm Theory of differential-difference operators implies that \( w \) is exponentially localized. Also note that the equations (4.34) and (4.35) establish that (6.3) admits a real valued solution of the form \( v_n^w(t) = \cos(\nu t) Re \ w(n + ct) - \sin(\nu t) Im \ w(n + ct) \). Finally, we claim that there are positive constants \( K_1, K_2 \) and \( K_3 > K_2 \) such that the function

\[
v_n^w(t) = e^{-\beta t}(K_1 - K_2 \phi(n + ct)) + K_3 \phi(n + ct)
\]

is a super-solution for (6.3) (For a proof of this claim in the \( \sigma = (1, 0) \) case see [33, Lem. 8.3]). Since \( v_n^w(0) = K_1 + (K_3 - K_2) \phi(n) > K_1 \) and \( v_n^w(0) = Re \ w(n) \) is exponentially localized it follows that \( v_n^w(t) \leq v^+(t) \) for all \( t > 0 \), where we have rescaled \( w \) so that \( \|Re \ w\|_\infty < K_1 \). Taking the limit as \( k \to \infty \) along the subsequence \( t_k = \frac{2\pi k}{i\nu} \) yields \( Re \ w(\xi) \leq K_3 \phi(\xi) \). Let \( C = \inf \{ \kappa \mid Re \ w(\xi) \leq \kappa \phi(\xi) \} \). Since \( C \phi(n + ct) \) is a solution which initially lies above the eigensolution \( v_n^w \) it does so for all time. Since these solutions touch at \( t = \frac{2\pi k}{\nu} \) it follows that they are identical, hence that \( \nu = 0 \). This establishes (HS)\(_1\).

We now establish (HS)\(_2\). In light of (HS)\(_{\text{ess}}\), the hypothesis (HS)\(_2\) can only fail if there is an eigenvalue in the closed right half plane for some \( \omega \neq 0 \). Similar to the argument for (HS)\(_1\), we shall assume that for some \( \omega \), the operator \( L_\omega \) has an eigenvalue \( \alpha + i\nu \) with \( \alpha \geq 0 \) and leverage the comparison principle to show that \( \omega = \nu = 0 \). Suppose that \( L_\omega w = (\alpha + i\nu)w \). As above, it follows from (4.34) and (4.35) that (6.3) admits a real valued solution \( v_n^\omega(t) = e^{i\nu t} \cos(\nu t + \omega t) Re \ w(n + ct) - \sin(\nu t + \omega t) Im \ w(n + ct) \). Comparing to \( v^+ \) yields that \( \alpha \leq 0 \) and that \( Re \ w \leq K_3 \phi \). Now restrict attention to \( \alpha = 0 \), compare \( v^\omega \) to \( C \phi \) with \( C \) defined as above, and use Lemma 6.1 with \( t = \frac{2\pi k}{\nu} \) to see that \( Re \ w = K_3 \phi \) and hence that \( \omega = \nu = 0 \).

The hypothesis (HS)\(_1\) is more difficult to verify, except in the case of special directions of propagation.

**Lemma 6.3.** Suppose \( \sigma = (1, 0) \) or \( \sigma = (1, 1) \) and \( \rho > \rho_\ast(\sigma) \). Then hypothesis (HS)\(_1\) holds for model equation (1.1)

**Proof.** We can compute

\[
[\partial_\xi^2 L_\omega]_{\omega=0}\phi(\xi) = -\sigma_1^2(\phi(\xi + \sigma_1) + \phi(\xi - \sigma_1)) - \sigma_2^2(\phi(\xi + \sigma_2) + \phi(\xi - \sigma_2)) < 0,
\]

(6.6)
giving us the desired negative sign for the first term \( \int_{\mathbb{R}} \psi(\xi), [\partial_\xi^2 L_\omega]_{\omega=0}\phi(\xi) \) in (2.34). This computation is valid for all \( \sigma \).

In the special cases \( \sigma = (1, 0) \) and \( \sigma = (1, 1) \), the map \( \omega \mapsto L_\omega \) is symmetric with respect to \( \omega \), which implies that \( [\partial_\omega \lambda_\omega]_{\omega=0} \) and \( [\partial_\omega \phi_\omega]_{\omega=0} \) both vanish and hence the second term disappears.

Although our condition cannot be verified for discrete Nagumo with cubic nonlinearity in general directions; there do exist other nonlinearities, e.g., nonlinearities similar to the cubic-like nonlinearity
in [1], for which explicit solutions are known for general rational directions of propagation. To make statements for the Nagumo equation with cubic nonlinearity and more general $\sigma$, we turn to numerics.

Figures 1 and 2 show the dependence of the Melnikov integral on $\sigma$ and $\rho$. For the parameters we have investigated we see non-vanishing Melnikov integrals so long as $\rho > \rho^*(\sigma)$. However, there does not appear to be any obvious structure such as monotonicity that we can exploit to prove analytically that the Melnikov integral is non-vanishing.

The computations were performed using the numerical method developed in [23]. In particular, we search for wave solutions of the form

$$u_j(t) = \Phi(j - ct), \quad \lim_{\xi \to \pm \infty} \Phi(\xi) = \pm 1,$$

by numerically solving the functional differential equation

$$c\Phi'(\xi) = \gamma \Phi''(\xi) + [\Phi(\xi \pm \cos \theta) + \Phi(\xi \pm \sin \theta) - 4\Phi(\xi)] + g(\Phi(\xi); \rho).$$

Notice the extra $\gamma \Phi''(\xi)$ term. To make use of robust codes to solve two-point boundary value differential equations and to avoid numerical issues that arise in the singular limit $c \to 0$, we follow the approach used in [14, 23] and add this extra term in (6.8), with $\gamma = 10^{-6}$, $\gamma = 10^{-5}$ or $\gamma = 10^{-4}$ (depending on context; see captions). We refer the reader to [22, 23] for numerical and theoretical results concerning the limit $\gamma \to 0$. These results strongly suggest that the region of propagation failure can be accurately determined by using small but practical values of $\gamma > 0$. In particular, the numerical results presented in this section were verified by repeating a subset of the calculations with different values of $\gamma$ where possible.

To compute the Melnikov constants, one needs to have detailed information on the adjoint eigenfunction $\psi$, and the rotated first derivatives $\lambda_1 := -i[\partial_\omega \lambda'_\omega]_{\omega=0}$ and $\phi_1 := -i[\partial_\omega \phi'_\omega]_{\omega=0}$. These were also computed numerically. In particular, the actual equations used to determine $\psi$ are given by

$$-\gamma \psi''(\xi) - c\psi'(\xi) = [\psi(\xi \pm \cos \theta) + \psi(\xi \pm \sin \theta) - 4\psi(\xi)] + Dg(\Phi(\xi))\psi(\xi) + \phi(\xi),$$

$$\lambda'_0(\xi) = 0,$$

Here the $\pm$ signs mean both terms are evaluated and added together.
with boundary conditions \( \psi(-L) = 0, \psi(L) = 0 \) and \( \psi(0) = 1 \) for some large \( L > 0 \). The actual equations used to compute \( \phi_1 \) and \( \lambda_1 \) are given by

\[
- \gamma \phi''_1(\xi) + c \phi'_1(\xi) = [\phi_1(\xi \pm \cos \theta) + \phi_1(\xi \pm \sin \theta) - 4 \phi_1(\xi)]
+ Dg(\Phi(\xi)) \phi_1(\xi)
\pm \sin(\theta) \Phi'(\xi \pm \cos \theta) \pm \cos(\theta) \Phi'(\xi \mp \sin \theta)
- \lambda_1(\xi) \Phi'(\xi),
\]

(6.10)

\[
\lambda_1(\xi) = 0,
\]

again with boundary conditions \( \phi_1(-L) = 0, \phi_1(L) = 0 \) and \( \phi_1(0) = 1 \).

## 7 Discussion

In this paper we have established the stability of planar fronts travelling in rational directions through two-dimensional lattices with nearest-neighbour interactions, under reasonable spectral hypotheses. Lattices in three or more spatial dimensions can be treated using the exact same techniques. Based on the PDE results [26], we even expect faster rates of decay to occur. This could even considerably simplify the nonlinear analysis by eliminating the problematic slowly decaying nonlinearities.

The restriction to nearest-neighbour interactions is of course purely artificial and many other variants could be considered. For example, in the case of the Nagumo LDE (1.1), it would be interesting to see what the effects of a cross-shaped Laplacian would be on the decay rate of perturbations to waves travelling in the direction \((1, 1)\).

Our restriction to \((\sigma_1, \sigma_2) \in \mathbb{Z}^2\) is of a more serious nature. However, we do believe that the spirit of our approach can be extended to irrational directions. Indeed, the difficulties that need to be overcome seem to be primarily technical in nature. For example, the Fourier transform in the transverse direction would not map the sequence space \( \ell^2(\mathbb{Z}; \mathbb{R}^d) \) into \( L^2([-\pi, \pi], \mathbb{R}^d) \), but would be a linear map from \( L^2(\mathbb{R}; \mathbb{R}^d) \) onto itself. As a first consequence, one can no longer use the embeddings \( \ell^1(\mathbb{Z}; \mathbb{R}^d) \subset \ell^2(\mathbb{Z}; \mathbb{R}^d) \subset \ell^\infty(\mathbb{Z}; \mathbb{R}^d) \), which implies that any bounds on the nonlinear terms would rely on the Sobolev embedding \( H^1(\mathbb{R}; \mathbb{R}^d) \subset L^\infty(\mathbb{R}; \mathbb{R}^d) \). A second consequence is that one can no longer restrict the Fourier frequency \( \omega \) to the compact interval \([-\pi, \pi]\). This forces a sharpening of the condition \((\text{HS2})_\omega\). However, similar complications were successfully handled in [26], emboldening us in our view that they will not present a fundamental obstacle in the current setting.

In establishing our spectral hypotheses for (1.1) in §6, we made extensive use of the fact that the Nagumo equation is scalar and enjoys a comparison principle. It is natural to consider what can be achieved by using the comparison principles directly and avoiding the intermediate "spectral stability implies nonlinear stability" theorem. The work [22] uses comparison principles to establish multidimensional stability for the PDE \( u_t = \Delta u + g(u) \) and many aspects of the argument can be carried over the lattice. However, after some effort, we have as yet been unable to control new terms generated by the anisotropy of the lattice except in the cases \( \sigma = (1, 0) \) and \( \sigma = (1, 1) \), in which case these terms are absent or benign. We note that [2], which studies multidimensional stability for traveling waves in higher dimensional anisotropic nonlocal equations, also restricts attention to the \( \sigma = (1, 0) \) case and its higher dimensional analogs. The advantage of having an approach based on comparison principles is that follow-up questions concerning the basin of attraction of the travelling wave and the presence of obstacles are much easier to address.
