Abstract

The contribution of investment in currency trading in economic growth of a nation cannot be over emphasized. Hence, the examination of the risk involved in such trading because of volatility in foreign exchange rate. Time series data and model were used in this study. The monthly exchange rate of four major foreign currencies in Nigeria namely the US Dollars (USD), the Great Britain Pounds (GBP), the EURO and CFA Francs against Nigerian Naira (NGN) from January, 2004 to December, 2019 were extracted from website of Central Bank of Nigeria (CBN) with an open access to the public. Due to the volatile nature of the exchange rate, the Generalized Autoregressive Conditional Heteroscedastic (GARCH) model was a suitable model used at order 1 for parsimony to determine volatility used in computing Value at Risk (VaR). It was discovered that the maximum loss (risk), measured by VaR, that can occur at 95% confidence interval for twelve months forecast of trading with GBP was the highest, among the four currencies, with percentage loss of between 15.5% to 16.2%. While the CFA has the lowest risk with VaR between 0.02% to 0.03%. Based on the findings, the risk of investing in foreign exchange is the highest when trading in GBP with attendant high returns due to large fluctuations up and down of the exchange rate. This study will help investors to study the pattern of risk and returns and decide on the foreign currency to trade on. The government should put policies in place to encourage existing investors and new investors that want to invest on foreign exchange to create employment, since the risk involved can be determined as it is done in this study.
Keywords: Exchange rate; volatility; value at risk; loss; foreign currencies.

1 Introduction

Exchange rate is the price of one currency in terms of another currency which makes it possible to convert domestic currencies to foreign currency. The currencies exchange activities are carried out by foreign exchange market in different forms which include online forex trading, foreign exchange spot market, foreign exchange forward market, foreign exchange futures market, foreign exchange swap, foreign exchange option and two-way quote system. The foreign exchange market is where the exchange is carried out in a globally decentralized market involving a global network of banks, corporations and individuals [1]. The exchange rates are of two types; the official exchange rate and parallel exchange rate, but the data in this study is based on the official exchange rate in Nigeria.

Trading on foreign exchange has been a long time business and it has contributed immensely to economic activities of a nation with Nigeria not an exception. The exchange rate is very volatile in such a way that there can be price movement in seconds. The volatility do increase the uncertainty that surrounds overseas investments, suppressing foreign direct investment inflows as multinational corporations are faced with an opportunity cost of not ‘waiting’, before committing huge sum of money as capital [2].

The activities of foreign exchange market is of great important to the economic growth of Nigeria. This assertion was supported by [3] in a study carried out to empirically examine the contributions of the foreign exchange market to the economic growth of Nigeria discovered that there is a strong correlation between exchange rate and economic growth represented by Gross Domestic Product (GDP).

Investors stake their capital investing in buying and selling in the foreign exchange market where many use it as part of self-employment. Following recent anomaly in foreign exchange, there is an increasing important of the use of carry-trade strategy by investors [4]. The carry-trade is a strategy where investors invest funds in currencies with high nominal interest rates and obtain their funding from currencies with low interest rates [5,4].

The foreign exchange market is becoming highly volatile day by day making it more difficult to predetermine returns or risk even though it is an age long trend that the risk involve in trading cannot be overestimated which may be due to various reasons. For instance, during the 2008 global financial crisis, the risk in foreign exchange rate was a scourge that has always been a burden because of the weakening of the exchange rate over the strength of the world’s anchor currency [6]. This study is to empirically determine future risk of investing on trading in foreign exchange.

Therefore, estimation of risk involve in trading on foreign exchange through the use of appropriate probability to determine period by period risk is of great important to investors. Some of the methods are VaR estimation and the forecast using the Monte-Carlo simulation [6], historical simulation method [7,8] and parametric method [9].

The adoption of flexible exchange-rate regimes in Nigeria in 1986 brought about excessive volatility of the Naira against major exchange rates [10]. The exchange rate volatility has effects on local investment by having positive or negative influence on prices of goods and services in the economy [11]. The dynamics of foreign exchange rates have in recent years increase its impact on the overall macroeconomic situation in different nations of the world, especially where domestic monetary policies of such a country cannot influence the world interest rates [12].

Due to this volatile nature of the exchange rate investors scramble for information to keep them abreast on their business. Those involve in foreign exchange (forex or fx) want to know which currency to buy or sell at a given point of time to reduce risk of losing their capital.

Therefore, information on the risk of investing in foreign exchange market becomes pertinent to safeguard loss that sent investors out of the foreign exchange trading business. Hence, the need to work closely on Value at Risk (VaR) as a clue on what the future holds for the business. Value at risk can be described as a popular
measure of risk used in the financial industry. It gives, at the current date, the maximum future loss that is expected in an investment (foreign exchange trade inclusive) for a given level of confidence and maturity [13].

The volatility of exchange rate can be viewed as an important parameter to be considered in investing in foreign exchange market because it plays a very important role in determining risk which is the probability of loss. This article is to undertake an empirical study of the exchange rate time series to estimate and forecast volatility which in turn use to compute the probability of maximum loss otherwise known as value at risk (VaR). The VaR will give the direction of foreign exchange market towards a particular currency against Nigerian Naira (NGN) which investors should follow.

The GARCH model has been a useful tool for estimating volatility. [14] used the model GARCH(1,1) to estimate volatility in their study of forecasting value at risk (Var). The standard deviation of the model which is the volatility was directly used in calculating VaR and thereafter a 1-Head forecast of the VaR was carried out. This study adopted their method of using standard deviation (volatility) directly to calculate VaR but differ in forecasting VaR by using the forecasted volatility to estimate future VaR. This is closely related to the work of [15] where the forecasted deviation of returns, instead of volatility from GARCH, was used in determining future VaR. This will be used to determine the foreign currency to invest on with NGN for survival of the business.

The GARCH(1,1) model has become a widely used model in financial time series data in the 21st century studies. The model is adopted by most statistics and econometrics software packages and is favored over other stochastic volatility models by many economists due to their relatively simple implementation. The GARCH(1,1) model is simpler because it is based on stochastic difference equations in discrete time such as financial time series, making the likelihood function easier to handle than models in continuous time equations [16]. Hence the adoption of the model in this study.

2 Methodology

2.1 Source of data

The monthly exchange rate data use in this study is a publication in the website of Central Bank of Nigeria (CBN) with an open access to the public. The time series data is the official exchange rate of the four major foreign currencies US Dollars (USD), the Great Britain Pounds (GBP), the EURO and CFA France against Nigerian Naira (NGN) which covered the period of January, 2004 to December, 2019.

2.2 Generalised Autoregressive Conditional Heteroscedastic Model (GARCH)

The model adopted for this study is the GARCH (1,1) model. The use of GARCH models allow the conditional variance to change over time as a function of past errors, leaving the unconditional variance constant [17,18].

The model is given as

Mean equation:

\[ r_t^2 = \epsilon + \beta r_{t-1}^2 + \epsilon \]

The conditional variance equation:

\[ \sigma_{t|t-1}^2 = w + \alpha \epsilon_{t-1}^2 + \beta \sigma_{t-1}^2 \]

Where

\[ w \] is the constant in the model which must be positive
\[ \alpha \] and \[ \beta \] are the coefficients of the model which are non-negative
$\varepsilon_{t-1}^2$ is derived from conditional mean equation

$\sigma_{t-1}^2$ represents conditional variance and $\sqrt{\sigma_{t-1}^2}$ is taken as the volatility.

Among the competing models GARCH(1,1) has been chosen because of its advantage over others due to its simplicity and suitability to discrete time interval [16].

### 2.3 Value at Risk (VaR)

The parametric method of [9] VaR will be viewed in this study as a function of volatility and a certain confidence interval. This is given as $VaR = \sigma_{t-1} Z_{\frac{1-a}{2}}$ to determine the probability of maximum lost for 12 months ahead of December 2019; January to December, 2020 at 5% level of significance. This method will make it possible for monthly value at risk to be computed at ease as a probability of risk.

### 3 Results and Discussion

#### 3.1 Stationarity

The time plot of the exchange rate which is a tradition when working with time series are in Fig. 1a to 1b.

Fig. 1 (a-d). Showing time plot of USD, GBP, EURO and CFA respectively against NGN

The time plot of the four series of USD, GBP, EURO and CFA do not show evidence of stationarity in Fig. 1a to 1d. The focus of the study is on the returns series of the exchange rate which is measured by the change between the succeeding and preceding exchange rate.

\[ r = r_{t-1} - r_t \]

The plots of the return (difference) series of the four exchange rates are shown in Fig. 2a to 2d.
Fig. 2 (a-d). Showing time plot of the differencing of USD, GBP, EURO and CFA respectively against NGN

The plot of returns series of the four foreign currencies were stationary which was substantiated by Augmented DickeyFuller (ADF) test at 5% level of significance.

Table 1. Showing the ADF and P- values of USD, GBP, EURO and CFA returns series

| Series | ADF     | P- values | Decision |
|--------|---------|-----------|----------|
| USD    | -5.4568 | 0.01      | Stationary |
| GBP    | -6.7648 | 0.01      | Stationary |
| EURO   | -5.5495 | 0.01      | Stationary |
| CFA    | -5.9208 | 0.01      | Stationary |

The four currencies have P- values = 0.01 less than 0.05, which means that the four series are stationary at first differencing.

3.2 Estimation of GARCH(1,1) model parameters and diagnosing

The estimates of the model parameters of the four currency series are as follows.

Table 2. Estimates of the model parameters and Jarque-Bera Test of the USD, GBP, EURO and CFA Series with P- values in bracket

| Series | $\omega$     | $\alpha$     | $\beta$      | Jarque-Bera Test Statistic |
|--------|--------------|--------------|--------------|---------------------------|
| USD    | 1.068e+01    | 3.520e+01    | 1.000e-08    | 34504.47 (0)              |
| GBP    | 34.04366     | 0.32633      | 0.17626      | 377.6238 (0)              |
| EURO   | 25.7330      | 0.3135       | 0.1197       | 924.6257 (0)              |
| CFA    | 8.854e-05    | 4.959e-01    | 1.000e-08    | 67.58005 (2.109424e-15)   |

The Jarque-Bera test with P- values approximately zero in all cases absent of normality indicating the presence of hetroscedasticity in four series.

3.3 Volatility

The GARCH(1,1) applied on the returns series of exchange rate to get the estimate of the conditional variance where volatility is taken as the square root of the conditional variance was of good fit based on the QQ-Plot.
The four plot a, b, c and d in Fig. 3 exhibited almost the same behavior with attended high volatility at the same period of time that look like an outlier. The outlier is an extension of what was exhibited in Fig. 1 and Fig. 2. There was a sharp increase of the foreign exchange rate of the four currencies against the NGN in June, July and August, 2016. This was due to weakening NGN against the U.S. dollar since June, 2016 because of the scraping of the currency peg by the Central Bank which had kept it at an artificially high value of around 198 NGN per USD for more than one year [19]. Thereafter volatility started behaving in their respective former patterns. Further study in these should investigate the effect of such sharp increase.

3.4 Volatility FORECAST and VaR

The forecasted volatility for twelve months from January to December, 2021 were used to calculate VaR [9] as prediction of VaR for the ten months with $Z_{\frac{0.05}{2}} = Z_{0.975} = 1.96$

| Month | USD (\%) | VaRUSD (\%) | GBP (\%) | VaRGBP (\%) | EURO (\%) | VaREURO (\%) | CFA (\%) | VaRCFA (\%) |
|-------|----------|-------------|----------|-------------|-----------|-------------|---------|------------|
| Jan   | 3.28     | 6.42        | 7.91     | 15.50       | 5.46      | 10.70       | 0.01    | 0.02       |
| Feb   | 3.80     | 7.45        | 8.09     | 15.86       | 6.22      | 12.18       | 0.01    | 0.02       |
| Mar   | 3.97     | 7.78        | 8.18     | 16.04       | 6.52      | 12.77       | 0.01    | 0.02       |
| Apr   | 4.03     | 7.90        | 8.23     | 16.13       | 6.64      | 13.02       | 0.01    | 0.03       |
| May   | 4.05     | 7.94        | 8.25     | 16.17       | 6.70      | 13.13       | 0.01    | 0.03       |
| June  | 4.06     | 7.95        | 8.26     | 16.19       | 6.72      | 13.17       | 0.01    | 0.03       |
| July  | 4.06     | 7.96        | 8.27     | 16.20       | 6.73      | 13.19       | 0.01    | 0.03       |
| Aug   | 4.06     | 7.96        | 8.27     | 16.21       | 6.73      | 13.20       | 0.01    | 0.03       |
| Sept  | 4.06     | 7.96        | 8.27     | 16.21       | 6.74      | 13.20       | 0.01    | 0.03       |
| Oct   | 4.06     | 7.96        | 8.27     | 16.21       | 6.74      | 13.21       | 0.01    | 0.03       |
| Nov   | 4.06     | 7.96        | 8.27     | 16.21       | 6.74      | 13.21       | 0.01    | 0.03       |
| Dec   | 4.06     | 7.96        | 8.27     | 16.21       | 6.74      | 13.21       | 0.01    | 0.03       |
The USD VaR (maximum loss) in month of July to December got stabilized at 7.96% while January to June witnessed some form of instability but not too high. That of GBP start stabilizing from August with 16.21% risk of maximum loss of investment in foreign exchange market. The VaR of EURO exhibit a different behaviour by being stable only in the months of August and September at 13.2% and rise to 13.21% from October to December. The most stable of them all is CFA with only two maximum loss of 0.02% and 0.03% for January to March and April to December respectively.

4 Conclusion

The risk of investing in foreign exchange has its highest in GBP with attendant high returns due to large fluctuations up and down of the exchange rate. The next currency in terms of ranking by maximum loss risk of investment is USD followed by EURO. The least among the four is CFA with the lowest maximum loss. The level of risk determines returns, therefore making a choice of investment depends on the investor. An investor with a strong capital base can trade on GBP and USD, but those with weak capital base go for lower risk currencies as EURO but with more concentration on CFA in order to stay in the business. Change on fiscal policies also take tolls on exchange volatility as noticed by the spike in June, July and August, 2016 which investors can make advantage of it.
