Exact Bounded Boundary Controllability to Rest for the Two-Dimensional Wave Equation

Igor Romanov\textsuperscript{1}\textsuperscript{2} Alexey Shamaev\textsuperscript{3}\textsuperscript{4}

Abstract

The problem of the exact bounded control of oscillations of the two-dimensional membrane is considered. Control force is applied to the boundary of the membrane, which is located in a domain on a plane. The goal of the control is to drive the system to rest in a finite time.

Keyword: Controllability to rest, wave equation, boundary control, bounded control
MSC 2010: 35L05, 35L20, 35B37

1 Introduction

The problem of exact boundary controllability of oscillations of a plane membrane is considered. Control force has a restriction on its absolute value. We will prove that the plane membrane can be driven to rest in a finite time. Exact mathematical definitions will be provided. It should be noted that the given method for the proof in this article can be used in the case of any other dimension, but here the two-dimensional case is provided for clear and simple presentation.

The problem of full stabilization in a finite time in case of the distributed control is described in the monograph \cite{1}. This reference also contains the upper estimate for an optimal control time.

Previously the question of the control of oscillations of a plane membrane by means of boundary forces is considered by many authors (i. g. overviews of D. L. Russell \cite{2} and J. Lions \cite{3}, as well as the literature provided there). The monograph \cite{4} describes the task of stabilizing the oscillations of a restricted string by means of the boundary control, and proves that vibrations of the string can be driven to rest in a finite time under the condition of restriction imposed on an absolute value of the control function, and an estimate is provided for the time that is necessary for full rest. In monograph \cite{5} problems of the optimal control of systems with distributed parameters are studied and optimal conditions are stated, which are similar to conditions for systems with a finite number of freedom’s degrees. Although this method does not provide a constructive technique for finding an optimal control in many cases. In synoptic article \cite{3} the problem of exact zero-controllability of a membrane is considered, the existence of the boundary control is proven and the time estimate is given which is required for driving to rest. Here authors, while studying the problem in various formulations, often reject the requirement of optimality of the control and solve only the problem of controllability, which is much easier. What is more, problems with restrictions

of the force’s absolute value are not considered, explicit forms for control functions are not found, and only theorems of existence are proven.

The statement of the problem in the article essentially differs from the one in [2] and [3], because the value of control force on the boundary has to satisfy the condition: $|u(t, x)| \leq \varepsilon$. Note, here the aim is to find not an optimal control, but the admissible (satisfying initial restrictions) control.

2 The statement of the problem

Let us consider the initial-boundary value problem for the two-dimensional wave equation:

$$w_{tt}(t, x) - \Delta w(t, x) = 0, \quad (t, x) \in Q_T = (0, T) \times \Omega,$$

$$w|_{t=0} = \varphi(x), \quad w_t|_{t=0} = \psi(x), \quad x \in \Omega,$$

$$\frac{\partial w}{\partial \nu} = u(t, x), \quad (t, x) \in \Sigma,$$

where $\Omega$ is a bounded domain with a smooth boundary, $\nu$ — the outer normal to the boundary of the domain $\Omega$, $\Sigma$ is a lateral surface of a cylinder $Q_T$. Initial data $\varphi(x)$ and $\psi(x)$ are given and will be chosen in suitable Hilbert spaces, $u(t, x)$ is a control function defined on the boundary $\Gamma = \partial \Omega$.

Let $\varepsilon > 0$ be an given arbitrary number. Let us impose the constraint on the control function:

$$|u(t, x)| \leq \varepsilon,$$

(4)

The problem is to construct a control $u(t, x)$ satisfying inequality (4) such that the corresponding solution $w(t, x)$ to the initial-boundary value problem (1)—(3) and its derivative with respect to $t$ become $(C, 0)$ at some time $T$, i.e.

$$w(T, x) = C, \quad w_t(T, x) = 0,$$

(5)

for all $x \in \Omega$. In this case $C$ is some constant. If we obtained a control $u(t, x)$ such that conditions (5) are achieved then the system (1)—(3) is called controllable to rest.

The following theorem is the main result of this article.

Theorem 1. Let $\varphi(x) \in H^6(\Omega)$ and $\psi(x) \in H^5(\Omega)$ such that

$$\frac{\partial \varphi(x)}{\partial \nu} = 0, \quad \psi(x) = 0, \quad x \in \Gamma.$$

(6)

Then there are time $T$ and the control function $u(t, x)$, satisfying the restriction (4), such that the system (1)—(3) is controllable to rest.

The proof of Theorem 1 consists of two steps. The first step stabilizes the considered solution and its first derivative with respect to $t$ in a small vicinity of equilibrium $(C, 0)$ in the norm of $C^4(\Omega) \times C^3(\Omega)$, and the second step allows to drive to rest the system in this small vicinity.

3 The first step of the control

Here we state the task to stabilize a pair $(w(t, x), w_t(t, x))$ in an arbitrarily small vicinity of $(C, 0)$ in the norm of the space $C^{4,3}(\Omega) = C^4(\Omega) \times C^3(\Omega)$ where $w(t, x)$ is the solution to the system (1)—(3).
and \( w_t(t, x) \) is its first derivative with respect to \( t \). What is more the control function should satisfy the restriction (3).

We use the results of [2] for this purpose. The research considers a friction which is introduced on the boundary (or on a part of it) of \( \Omega \). The friction is given by the first derivative of \( w(t, x) \) with respect to \( t \), i.e. the initial-boundary value problem (1), (2) with boundary condition

\[
\frac{\partial w(t, x)}{\partial \nu} = -k \frac{\partial w(t, x)}{\partial t},
\]

where \( k > 0 \) is a friction coefficient.

According to the theorem’s condition we have \( \varphi(x) \in H^6(\Omega) \) and \( \psi(x) \in H^5(\Omega) \). It is known that in this case the solution \( w(t, x) \) to the problem (1), (2), (7) is such that \( w(t, x) \in C([0, +\infty); H^6(\Omega)) \) and \( w_t(t, x) \in C([0, +\infty); H^5(\Omega)) \). We note that it is necessary for \( \varphi(x) \), \( \psi(x) \) to satisfy the following condition:

\[
\frac{\partial \varphi(x)}{\partial \nu} = -k \psi(x), \quad x \in \Gamma.
\]

By virtue of (6) condition (5) is done for any \( k \).

Let us consider the energy of the system (1), (2), (7):

\[
E(t) = \int_{\Omega} \left( w_{x_1}^2(t, x) + w_{x_2}^2(t, x) + w_t^2(t, x) \right) dx.
\]

In [2] it is proven, because of the presence of friction on the boundary the dissipation of the system’s energy occurs, that

\[
\frac{dE(t)}{dt} \leq 0, \quad t \geq 0.
\]

What is more the estimate is correct

\[
E(t) \leq \frac{C_1(\varphi, \psi)}{1 + t}, \quad t \geq 0,
\]

where \( C(\varphi, \psi) \) is a constant, depending on the initial data of the system. Differentiating the equation (1), initial conditions (2), and also boundary condition (7) with respect to \( x_1 \) and \( x_2 \), we obtain the estimate for \( w(t, x) \):

\[
\int_{\Omega} \sum_{0<|\alpha|\leq6} |D_\alpha^2 w(t, x)|^2 dx \leq \frac{C_2(\varphi, \psi)}{1 + t}, \quad t \geq 0,
\]

\[
\alpha = (\alpha_1, \alpha_2), \quad |\alpha| = \alpha_1 + \alpha_2, \quad D_\alpha^2 = D_{\alpha_1}^2 D_{\alpha_2}^2, \quad D_{\alpha_j} = \frac{\partial^{\alpha_j}}{\partial x_j^{\alpha_j}}.
\]

The left side of the estimate (11) is the square of the seminorm in \( H^6(\Omega) \) of the function \( w(t, \cdot) \). We denote this seminorm as \( \| \cdot \|_{H^6(\Omega)} \). From (11) we obtain that \( \| w(t, \cdot) \|_{H^6(\Omega)} \to 0, \quad t \to +\infty \). Then let us prove for the solution \( w(t, x) \) that \( \| w(t, \cdot) - C \|_{H^6(\Omega)} \to 0, \quad t \to +\infty \), where \( C \) is some constant. We introduce:

\[
C = \frac{1}{|\Gamma|} \int_{\Gamma} \varphi(x) d\Gamma - \frac{1}{|\Gamma|} \int_{\Omega} \psi(x) dx,
\]

where \( |\Gamma| \) is a length of \( \Gamma \). Let \( w(t, x) = v(t, x) + C \) and consider a new initial-boundary value problem for \( v(t, x) \) (analogous to (1)–(3)). Using Friedrichs’ (Poincare) inequality we have

\[
\int_{\Omega} v^2(t, x) dx \leq C_3 \left\{ \int_{\Omega} \left( \frac{\partial v}{\partial x_1} \right)^2 + \left( \frac{\partial v}{\partial x_2} \right)^2 \right\} dx + \left( \int_{\Gamma} v(t, x) d\Gamma \right)^2.
\]
\[ \int_{\Gamma} v(t, x) d\Gamma = \frac{1}{k} \int_0^t \int_{\Gamma} \frac{\partial v}{\partial n} d\Gamma dt + \frac{1}{k} \int_{\Gamma} \varphi(x) d\Gamma - |\Gamma| C = \]

\[ = \frac{1}{k} \int_0^t \int_{\Omega} \Delta v(t, x) dx dt + \frac{1}{k} \int_{\Gamma} v_x(t, x) d\Gamma + \frac{1}{k} \int_{\Gamma} \varphi(x) d\Gamma - |\Gamma| C = \]

\[ = \frac{1}{k} \int_{\Omega} v_t(t, x) dx - \frac{1}{k} \int_{\Gamma} \psi(x) dx + \frac{1}{k} \int_{\Gamma} \varphi(x) d\Gamma - |\Gamma| C = \frac{1}{k} \int_{\Omega} v_t(t, x) dx \]

From the last estimations we obtain

\[ \|w(t, \cdot) - C\|_{L^2(\Omega)} \to 0, \quad t \to +\infty. \]

As for \( w_t(t, x) \) the situation is more trivial because from (10) we obtain

\[ \|w_t(t, \cdot)\|_{H^3(\Omega)} \leq \frac{C_3(\varphi, \psi)}{1 + t}, \quad t \geq 0. \]

We solve the problem (1), (2), (7) with the given initial conditions, then this solution is substituted to the only right part of the equality (7), and we obtain the boundary condition (3) for the initial-boundary value problem (1)—(3). In other words, we make the control function of the problem (1)—(3) be equal to

\[ u(t, x) = -k \frac{\partial w_0(t, x)}{\partial t}, \]

where \( w_0 \) is a solution to the problem (1), (2), (7).

Therefore it is proven (here we use Sobolev embedding theorem) that controlling for a long time, we can make the values

\[ \|w(T_1, \cdot)\|_{C^4(\overline{\Omega})}, \quad \|w_t(T_1, \cdot)\|_{C^3(\overline{\Omega})} \]

arbitrarily close to \((C, 0)\) at some time \( t = T_1 \).

Now let us show that the boundary control function \( u(t, x) \) can be sufficiently small, i.e. we may satisfy the restriction (4). Note that in virtue of (9)

\[ \max_{t \in [0, +\infty)} E(t) = E(0) = \int_{\Omega} \left( \varphi_{x_1}^2(x) + \varphi_{x_2}^2(x) + \psi^2(x) \right) dx. \]

Therefore we obtain

\[ \int_{\Omega} w_t^2(t, x) dx \leq \int_{\Omega} \left( \varphi_{x_1}^2(x) + \varphi_{x_2}^2(x) + \psi^2(x) \right) dx, \quad t \geq 0. \]

The last estimate of the integral, which is on the right side, depends on only initial data and does not depend on the friction coefficient. Hence differentiating the equation (11), initial condition (2) and boundary conditions (3) with respect to \( x_1, x_2 \), and also using embedding theorems, we obtain the restriction of absolute value of \( w_t(t, x) \) on the closure of cylinder \( Q_{T_1} \) by constant, which depends on only initial data. If the coefficient \( k \) is small enough, we achieve condition (4).
4 The second step of the control

Now we have a task to drive the system to rest. A pair of functions
\[ (w|_{t=0} = w(T_1, x), w_t|_{t=0} = w_t(T_1, x)) \]

is considered to be new initial data for the problem (1)–(3). Bearing in mind that according to the fact proven above these initial conditions are sufficiently close to \((C, 0)\) in the norm of the space \(C^{4,3}(\Omega)\). We shift now the solution \(w\) (first step of the control) on the value \(C\), i.e. we change \(w\) on \(w + C\) and consider the pair \((w|_{t=0} = w(T_1, x), w_t|_{t=0} = w_t(T_1, x))\) that is sufficiently close to \((0, 0)\).

Let us consider the domain \(\Omega_3\), which is \(\delta\)-vicinity of the domain \(\Omega\). Also let take an arbitrary pair \((w_0(x), w_1(x))\) from the space \(C^{4,3}(\Omega)\). Consider an extension operator \(E\). It is a linear continuous operator from the space \(C^{4,3}(\Omega)\) to \(C^{4,3}(\Omega_\delta)\) such that the support of the extended pair \((w_0^e(x), w_1^e(x))\) and its derivatives of 5th and 4th orders (respectively) inclusive belongs to \(\Omega_\delta\). Moreover
\[ (w_0^e(x), w_1^e(x)) = (w_0(x), w_1(x)), \text{ if } x \in \Omega. \]

Note that, outside \(\Omega_\delta\), the functions can be extended by zero to the whole plane. In a more general case, \(E\) was constructed in [6].

Extended in this way functions are denoted (as above) as \(w_0^e(x)\) and \(w_1^e(x)\), according to D. L. Russell. Let us consider the Cauchy problem for the equation of membrane’s oscillations on a plane \(R^2\):
\[ \begin{align*}
  &w_{tt}(t, x) - \Delta w(t, x) = 0, \quad (t, x) \in Q = (0, +\infty) \times R^2, \\
  &w|_{t=0} = w_0^e(x), \quad w_t|_{t=0} = w_1^e(x), \quad x \in R^2.
\end{align*} \]

It is known that the solution to the problem (9), (10) has the form (Poisson’s formula):
\[ w(t, x) = \frac{\partial}{\partial t} \left( \frac{1}{2\pi} \int_{|y-x|<t} \frac{w_0^e(y)dy}{\sqrt{t^2 - |y-x|^2}} \right) + \frac{1}{2\pi} \int_{|y-x|<t} \frac{w_1^e(y)dy}{\sqrt{t^2 - |y-x|^2}}. \]

We use the formula (14) for estimating the absolute value of the solution \(w(t, x)\) uniformly by the initial data. The absolute value of \(w(t, x)\) is estimated in case \(x \in \Omega_\delta\). We compute the first derivative with respect to \(t\) in the right part of (14):
\[ w(t, x) = \frac{1}{2\pi t} \int_{|y-x|<t} \frac{w_0^e(y) + (y-x) \cdot \nabla w_0^e(y)}{\sqrt{t^2 - |y-x|^2}} dy + \frac{1}{2\pi} \int_{|y-x|<t} \frac{w_1^e(y)dy}{\sqrt{t^2 - |y-x|^2}}. \]

As initial data \((w_0^e(x), w_1^e(x))\) have a compact support then there is large enough time \(t^* > 0\) such that for any \(t > t^*\) and for any \(x \in \Omega_\delta\) we obtain
\[ w(t, x) = \frac{1}{2\pi t} \int_{\Omega_\delta} \frac{w_0^e(y) + (y-x) \cdot \nabla w_0^e(y)}{\sqrt{t^2 - |y-x|^2}} dy + \frac{1}{2\pi} \int_{\Omega_\delta} \frac{w_1^e(y)dy}{\sqrt{t^2 - |y-x|^2}}. \]

Note that we choose \(t\) such as \(t^2 - |y-x|^2 \geq \alpha > 0\) for any \(x, y \in \Omega_\delta\).

The following rough evaluation follows from the explicit form of (16):
\[ \|w(t, \cdot)\|_{C^4(\Omega_\delta)} \leq \frac{C_1}{t} \|w_0^e\|_{C^4(R^2)} + \frac{C_2}{t} \|w_1^e\|_{C^4(R^2)}. \]
Differentiating \( w(t, x) \) with respect to \( t \), we obtain the rough estimate in the space of the pair of functions \( C^{4,3} (\Omega) = C^4 (\Omega) \times C^3 (\Omega) \)

\[
\| (w(t, \cdot), w_t(t, \cdot)) \|_{C^{4,3}(\Omega)} \leq \frac{M}{T} \| (w_0^e, w_1^e) \|_{C^{4,3}(R^2)}, \quad t > t^*,
\]

where a number \( M \) does not depend on initial data.

Further we use the method described in \([2]\) and applied to problems of the boundary controllability for a wave equation.

Let us consider some initial conditions \( w_0(x) \) and \( w_1(x) \), \( x \in \Omega \). We extend them to \( R^2 \) by means of a linear bounded operator \( E \). Then we obtain \( (w_0^e, w_1^e) = E(w_0, w_1) \). And the Cauchy problem \((9), (10)\) arises. Let \( w^s(t, x) \) be the solution to this Cauchy problem. Now consider any \textbf{large enough} time \( t = T_2 \).

We get \( (w^s(T_2, x), w_t^s(T_2, x)) \in C^{4,3}(\Omega) \). The restriction of the function \( w^s(T_2, x) \) and its derivative on the domain \( \Omega \) should be considered. It is obvious that in virtue of \((18)\) the following estimate is correct for \( t = T_2 \)

\[
\| (w^s(T_2, \cdot), w_t^s(T_2, \cdot)) \|_{C^{4,3}(\Omega)} \leq \frac{M}{T_2} \| (w_0^e, w_1^e) \|_{C^{4,3}(R^2)}. \tag{19}
\]

Let by definition \((w_0^{s*e}(T_2, x), w_t^{s*e}(T_2, x)) = E(w^s(T_2, x)|_{\Omega}, w_t^s(T_2, x)|_{\Omega}) \). Now let us have a look at the inverse Cauchy problem with initial conditions

\[
w(t, x)|_{t=T_2} = -w_0^{s*e}(T_2, x) \quad w_t(t, x)|_{t=T_2} = -w_1^{s*e}(T_2, x). \tag{20}
\]

Let \( w^i(t, x) \) be the solution to the inverse Cauchy problem with conditions \((20)\). In virtue of invertibility of the equation \((1)\) with respect to \( t \) the following estimate takes place:

\[
\| (w^i(0, \cdot), w_t^i(0, \cdot)) \|_{C^{4,3}(\Omega)} \leq \frac{M}{T_2} \| (w_0^{s*e}(T_2, x), w_t^{s*e}(T_2, x)) \|_{C^{4,3}(R^2)}. \tag{21}
\]

Obviously the solution of the Cauchy problem with initial conditions such as

\[
w|_{t=0} = w_0^e(x) + w^i(0, x), \quad w_t|_{t=0} = w_1^e(x) + w_t^i(0, x), \quad x \in R^2,
\]

identically equals zero in \( \Omega \) as well as its first derivative with respect to \( t \) at the time \( t = T_2 \). Now let us consider the restriction of the right parts of \((22)\) in the domain \( \Omega \). We regard the initial conditions (the restriction of right parts of \((22)\)) in the problem of boundary controllability:

\[
w|_{t=0} = w_0(x) + w^i(x, 0), \quad w_t|_{t=0} = w_1(x) + w_t^i(0, x), \quad x \in \Omega. \tag{23}
\]

Note that it is the value of the corresponding solution to the Cauchy problem in \( R^2 \) with the initial conditions \((22)\) to determine the required control function on the boundary of \( \Omega \).

A pair \((w^i, w^i_t)(0, x)\) is derived from pair \((w_0(x), w_1(x))\) by means of applying a linear continuous operator, let us denote it as \( L \), with the norm less than 1 (consequence from estimates \((19)\) and \((21)\)). Obviously the sums in right parts \((23)\) generate all elements of the space \( C^{4,3}(\Omega) \). Indeed, \((23)\) can be written as:

\[
(I + L)(w_0(x), w_1(x)) = (w|_{t=0}, w_t|_{t=0}), \tag{24}
\]

where \( I \) is the identical operator. Hence, as \( \|L\| < 1 \), so the operator \( I + L \), which acts from \( C^{4,3}(\Omega) \) to itself, is invertible.
Now let us represent the control function (second step) in the following form:

\[ u(t, x) = \frac{\partial}{\partial t} PK^1 \left[ \left( I + (-K^{T_2}) E R K^2 \right) E \left( I + R(-K^{T_2}) E R K^2 \right) \right]^{-1} \left( w|_{t=0}, w|_{t=0} \right), \ x \in \partial \Omega, \]

where \( R \) is a restriction from \( R^2 \) to \( \Omega \) and \( K^{T_2}, K^2 \) are resolving operators of the Cauchy problem and \( P \) is a projection: \((a, b) \rightarrow a\). We write minus before \( K^{T_2} \) because of \( 20\).

Thus we have proven that the system with smooth initial conditions can be driven to rest by means of extending them on the full plane. It is the method to extend which determines a program of the boundary control. Let us show now that if the initial conditions have small enough absolute values, we can drive the system to rest by means of a boundary control which has a small absolute value.

We regard that in the problem \((1)-(3)\) the value of the solution \( w(t, x) \) and the value of its derivative \( w(t, x) \) at \( t = T_1 \) are small enough in norms of spaces \( C^4(\overline{\Omega}) \) and \( C^3(\overline{\Omega}) \) respectively.

Let \((w|_{t=0}, w|_{t=0})\) be rewritten according to the formula \((23)\). As continuous operator \( I + L \) invertible, so according to Banach’s theorem an invertible operator is continuous too. Hence choosing \((w|_{t=0}, w|_{t=0})\) sufficiently small, we can make \((w_0(x), w_1(x))\) be sufficiently small as well. Now let consider the sums \((22)\), which determine data \((w|_{t=0}, w|_{t=0})\). Extending these sums on the whole plane by the method above, we obtain initial data \((22)\). So we can write down the solution to the Cauchy problem with initial conditions \((22)\):

\[
w(t, x) = \frac{\partial}{\partial t} \left( \frac{1}{2\pi} \int_{|y-x|<t} \frac{(w_0^e(y) + w_0(t, 0, y))dy}{\sqrt{t^2 - |y-x|^2}} \right) + \frac{1}{2\pi} \int_{|y-x|<t} \frac{(w_1^e(y) + w_1(t, 0, y))dy}{\sqrt{t^2 - |y-x|^2}}.
\]

Let us rewrite the last formula by solving the inverse Cauchy problem:

\[
w(t, x) = \frac{\partial}{\partial t} \left( \frac{1}{2\pi} \int_{|y-x|<t-T_2} \frac{w_0^e(T_2, y)dy}{\sqrt{(t-T_2)^2 - |y-x|^2}} \right) - \frac{1}{2\pi} \int_{|y-x|<t-T_2} \frac{w_1^e(T_2, y)dy}{\sqrt{(t-T_2)^2 - |y-x|^2}}.
\]

In order to solve the Cauchy problem with initial conditions \( w_0^e(x) \) and \( w_1^e(x) \) the law of conservation of energy is used:

\[
\int_{R^2} \left\{ \left( w_{x_1}^e(t, x) + w_{x_2}^e(t, x) \right)^2 + \left( \frac{\partial w_0^e(x)}{\partial x_1} \right)^2 + \left( \frac{\partial w_0^e(x)}{\partial x_2} \right)^2 \right\} dx = 0
\]

\[
\int_{R^2} \left\{ \left( \frac{\partial w_0^e(x)}{\partial x_1} \right)^2 + \left( \frac{\partial w_0^e(x)}{\partial x_2} \right)^2 + (w_1^e(t, x))^2 \right\} dx.
\]

Bearing in mind that supports of functions \( w_0^e(x) \) and \( w_1^e(x) \) are in \( \overline{\Omega}_3 \), and supports of their derivatives with respect to all variables including the third order are located in \( \overline{\Omega}_5 \) too. Note that \( (w^e(t, x), w_1^e(t, x)) \) is an element of \( C^{3,2}(R^2) \) for any \( t > 0 \).

Now differentiating the equation \((12)\) and initial conditions \((13)\) with respect to variables \( x_1, x_2, \) we obtain the estimate

\[
\| w^e(t, \cdot) \|_{H^3(R^2)} \leq \| w_0^e \|_{H^3(\Omega_3)} + \| w_1^e \|_{H^2(\Omega_5)},
\]
where \( \| \cdot \|'_{H^3(\Omega)} \) is a seminorm (term
\[
\int_{\mathbb{R}^2} (w^s(t,x))^2 \, dx
\]
is absent). The solution \( w^s(t,x) \) has a compact support \( G_t \) in \( \mathbb{R}^2 \) at each moment \( t \) because of the finite speed of the wave propagation. Let us take a sufficiently large circle \( D \) such as \( G_t \subset D, t \in [0, T_2] \). Then the seminorm \( \| \cdot \|'_{H^3(D)} \) is a norm. Therefore we obtain
\[
\| w^s(t, \cdot) \|_{H^3(D)} \leq CF \| w^0_e \|_{H^3(\Omega_{\delta e})} + CF \| w^1_e \|_{H^2(\Omega_{\delta e})}.
\]
Taking into account the last estimate and the Sobolev embedding theorem we get
\[
\| w^s(t, \cdot) \|_{C^1(\overline{\Omega})} \leq CS \| w^0_e \|_{H^3(\Omega_{\delta e})} + CS \| w^1_e \|_{H^2(\Omega_{\delta e})}.
\]
(28)

Summing up, it is proven that the solution \( w^s(t, x) \) can be made sufficiently small in the norm \( C^1(\overline{\Omega}) \) for any \( t \in [0, T_2] \). The same argument may be applied to the solution of the inverse Cauchy problem with initial conditions \(-w^s_0(T_2, x)\) and \(-w^s_1(T_2, x)\) (see (26)). In this case it is important that functions \( w^s_0(T_2, x) \) and \( w^s_1(T_2, x) \) in virtue of inequality (18) are "small" in \( C^{4,3} \), if \( w^0_e(x) \) and \( w^1_e(x) \) are "small". Hence the restriction of the normal derivative of the solution to the Cauchy problem \( \Omega \), \( \Gamma \) on the boundary of \( \Omega \) (Neumann condition of the problem of controllability) is less than given \( \varepsilon \) with respect to absolute value. The latter means that the required restriction \( \| u(t, x) \| \leq \varepsilon \) is satisfied.
