**Figure S1:** The molecular arrangement of bent-core molecules considering the tilt and the polarity in adjacent layers of the SmCP phase. The smectic layers are perpendicular to the drawing plane. The different molecular symbols correspond to opposite bent directions perpendicular to the drawing plane: Symbol having a circle in the centre means front view; symbols with a cross means back-side view. Both directions of the bend mean also opposite polar axes. The red and blue symbols indicate layers of different chirality. In the upper part, on the left, the racemic antiferroelectric state is sketched, which can be switched to the ferroelectric state on application of an electric field, shown on the right. In the lower part, the homochiral antiferroelectric states are sketched on the left, in which the tilt direction alternates. The field-induced arrangement in the homochiral ferroelectric state is shown on the right.

Polar smectic C phases (SmCP) are designated with the following symbols: $\textbf{P}$ stands for **polar**, the suffixes $\textbf{A}$ or $\textbf{F}$, added to $\textbf{P}$, indicate **antiferroelectric** or **ferroelectric** states (SmCP$_A$ and SmCP$_F$, respectively). A **synclinic** or an **anticlinic** interlayer correlation is indicated by the suffixes $\textbf{s}$ or $\textbf{a}$ after C (i.e., SmC$_s$P, SmC$_a$P). In the so-called homochiral (homogeneous chiral) structures all layers have the same handedness, whereas in the racemic state the chirality alternates from layer to layer.

One possible interpretation of the X-ray data for **OH 4b** in agreement with the other measurements is the following:

The additional reflections may be indexed as a 11 reflection of an oblique 2D lattice. Assuming the -11 reflection to be superimposed by the very strong ring-like 01 layer reflection, lattice parameters can be determined to \( a = 6.6 \text{ nm} \), \( b = 4.8 \text{ nm} \), and \( \gamma = 111.5^\circ \). Comparing the volume \( V_U = 15.32 \text{ nm}^3 \) of a hypothetical 3D unit cell with the molecular volume in the liquid crystalline phase \( V_{M,lc} = 1.49 \text{ nm}^3 \), about 10 molecules occupy the cross section of the unit cell (cp. Table S3). From the azimuthal distribution of the wide angle scattering along (\( \chi \)-scan), the tilt angle \( \theta \) of the molecules with respect to the layer normal can be determined to be \( \sim 20^\circ \), which is in good agreement with the optically determined value. From this tilt and the \( d \)-value of the 01 reflection (layer thickness 4.5 nm) an effective molecular length of \( L_{\text{eff}} = 4.8 \text{ nm} \) can be calculated according to \( L_{\text{eff}} = d/cos\theta \). Using CPK models and with the assumptions that the bending angle amounts to nearly 120° and that all chains are in an all-trans configuration, a length \( L_{\text{calc}} = 5.46 \text{ nm} \) would be obtained. The difference (\( L_{\text{eff}} = 4.8 \text{ nm} \) and \( L_{\text{calc}} = 5.5 \text{ nm} \)) indicates that the molecular configuration assumed in this calculation is not correct for compound **OH 4b**. Another bending angle, a high portion of gauche conformers, or an interdigitation of the terminal chains could be the reason for the difference. The relatively large bromine atom at the central part of the molecule requires an increased lateral space, which could make easier an interdigitation of hydrocarbon chains of adjacent layers.

Synthesis of the compounds: Experimental procedures and analytical data

The preparation of the final compounds is sketched in the Schemes 2–5 (main paper). Because several reactions were performed by using similar experimental conditions, three general procedures are given here. In the second part new intermediates are described. In the third part the preparation of the final products is reported, the melting temperature and the mesophase behaviour are summarised in the corresponding Tables 2–5 (main paper).

1. General procedures

**General procedure 1 (GP1):**

**Esterification of benzoic acids with phenols by the carbodiimide method**

The substituted benzoic acid (0.005 mol), the corresponding phenol (0.005 mol) and a catalytic amount of DMAP were dissolved in 50 mL of dry dichloromethane. Dicyclohexylcarbodiimide (1.14 g, 0.0055 mol) was added and the mixture was stirred at rt for about 24 h. The reaction process was controlled by TLC. After completion the precipitated dicyclohexylurea was separated, the solvent evaporated and the crude material purified by recrystallization.
**General procedure 2 (GP2)**  
Condensation of anilines with benzaldehydes giving Schiff bases  
To a slurry of the substituted benzaldehyde (0.005 mol) and the corresponding aniline (0.005 mol) in 30 mL ethanol, a catalytic amount of acetic acid was added and the mixture heated under reflux for about 10 min. Stirring was continued for 24 h at rt. The precipitate was filtered off and the crude compound was purified by recrystallization. For the preparation of the final products OH 5 and OH 6 only 0.0025 mol of the substituted diamine was used.

**General procedure 3 (GP3)**  
Acylation of 2,4-dihydroxybenzaldehyde using acid chlorides  
To a slurry of the substituted benzoic acid (0.01 mol) in 50 mL of dry dichloromethane and one drop of pyridine, oxalyl chloride (0.04 mol as 2 M solution in dichloromethane) was added and the mixture refluxed for 2 h. The solvent was evaporated, 50 mL dichloromethane was added again to remove the residue of oxalyl chloride under vacuum together with the solvent. The crude acid chloride was dissolved in 30 mL of dry toluene. After addition of 2,4-dihydroxybenzaldehyde (0.005 mol) and DMAP (catalytic amount) 0.011 mol triethylamine was slowly added dropwise. Stirring was continued for 6 h at 65 °C and afterwards for 10 h at rt. After cooling, the reaction mixture was filtered to remove the triethylamine hydrochloride, and the solvent evaporated in vacuum. The crude compound was purified by recrystallization.
