SUMMARY – A cross-sectional study was carried out in Brod-Posavina County, Croatia, to assess the prevalence of allergic diseases and atopy, as well as to investigate the possible etiologic factors for asthma, allergic rhinitis and eczema in childhood. The study included 1687 schoolchildren aged 10-11 years. Data were collected using standardized International Study of Asthma and Allergies in Childhood (ISAAC) Phase II written questionnaire. Skin prick tests were performed to provide an objective measure of atopy, defined as skin reactivity to one or more allergens. Lifetime prevalence of wheezing was 22.7%, rhinitis symptoms 22.5%, and eczema symptoms 17.9%. Period prevalence in the past 12 months was 7.9% for attacks of wheezing, 9.9% for rhinoconjunctivitis symptoms, and 10.1% for eczema symptoms. Of the children in which skin prick test was performed, 20.2% were positive for at least one of the allergens used, with house dust mite sensitization being the most frequent one. Risk factors for allergic disease include allergic disease in family, atopy, sensitization to indoor and outdoor allergens, and environmental tobacco smoke exposure at home. International comparison with the results of other ISAAC Phase II studies showed the Brod-Posavina County to be an area with moderate prevalence of atopy and current asthma symptoms.

Key words: Hypersensitivity; Prevalence; Risk factors; Asthma; Rhinitis, allergic; Dermatitis, atopic; Cross-sectional studies; Child; Croatia

Introduction

Allergic diseases with complex etiology, such as asthma, allergic rhinitis and eczema, are the most common chronic conditions in childhood. The prevalence of these allergic diseases has constantly and significantly increased worldwide in recent decades1. Over the last several years, countries in transition have experienced a dramatic increase in allergic diseases2. However, publications from high-income countries at the end of the 20th century reported a moderate decrease in asthma and atopic diseases in older age groups of children3-6. Moreover, according to data from the International Study of Asthma and Allergies in Childhood (ISAAC) Phase III, previous observations that asthma is more prevalent in affluent than in non-affluent countries7 cannot be considered accurate. This epidemiologic survey has documented great variability in asthma and allergic disease prevalence not just among different countries, but also among centers in the same country. The cause of the recorded increase and differences in the prevalence is complex. It has been assumed that changes in local environmental exposures, combined with ge-
Neda Aberle et al. Allergy among children in eastern Croatia

Genetic susceptibility could account for the observed variability. The observed environmental risk factors for allergic diseases include indoor and outdoor environment, diet, lifestyle, stress, use of antibiotics, and family size. Complete development of allergic phenotype is influenced by the period in which it has occurred (early childhood – prenatal and early postnatal). However, epidemiologic data indicate differences in risk factors for asthma among countries.

Although researchers in Croatia (a country that is part of both Mediterranean and Central Europe) have previously written about asthma, rhinitis and eczema in various parts of Croatia, there was little data about atopy, environmental exposures and lifestyle that could be associated with asthma in the Croatian population. Considering the great variability of published data in terms of prevalence of allergic diseases among different centers in Croatia and scarce data published on predisposing exposures, the aim of our study was to assess the prevalence of asthma, allergic rhinitis, eczema and atopy in childhood in Brod-Posavina County (eastern Croatia), as well as the risk factors for these allergic diseases.

Materials and Methods

Study design and setting

This cross-sectional study was carried out in Brod-Posavina County, which is part of Slavonia, one of the four historical regions of Croatia. It is located in the Pannonian Basin, which is bordered by the Danube, Drava and Sava rivers. The western part of the region consists of the Sava and Drava valleys, and the mountains and hills surrounding the Požega valley, the highest being Psunj with 984 m above sea level. The eastern part of the region consists of plains. Slavonia enjoys a moderately warm and rainy continental climate, with relatively low precipitation.

Parental consent was obtained before the study. The study was approved by the ethics committees of the participating institutions.

Participants

Between September 2007 and June 2008, children aged 10–11 from all elementary schools in the Brod-Posavina County (N=2224) were asked to participate in the study, which included a questionnaire for parents and skin prick test (SPT).

Methods

Data were collected using the standardized ISAAC Phase II written questionnaire. The core questionnaire includes demographic characteristics: gender of the child, parental age and education, family history of atopy, and questionnaires on wheezing, rhinitis and eczema.

Supplementary questionnaires include the risk factor questionnaire, inquiring about early days: birth weight, breastfeeding, attendance of nursery or kindergarten, and number of older siblings. The second part of the questionnaire refers to characteristics of the child’s home during conducting the survey and during the first year of life: pet ownership, contact with farm animals, cooking/heating fuel, surroundings and environmental tobacco smoke exposure.

Skin prick test was performed to provide an objective measure of atopy, defined as skin reactivity to one or more allergens. Sensitization to the following eight allergens was assessed: Dermatophagoides (D.) pteronyssinus, dog, cat, egg, peanut, ragweed, birch and mixed grass pollen. Standardized allergen extracts and control solution were obtained from Stallergens (France). A wheal size ≥3mm after subtraction of negative control was considered positive. The presence of visible flexural dermatitis was determined by skin examination.

Statistical analysis

Statistical analysis was carried out using SPSS 19 (SPSS Inc., Chicago, IN, USA). Symptom prevalence was calculated by dividing the number of positive responses to each question by the number of completed questionnaires. We analyzed associations between environmental exposures and main research outcomes (current wheezing, current rhinoconjunctivitis and current eczema) using logistic regression. Results were presented as p values, odds ratios (OR) and 95% confidence intervals (95%CI) as a measure of effect size.

Results

Of 2224 children that were approached, 1687 agreed to participate in the study (response rate 75%; 847 (50.2%) male and 840 (49.9%) female). Description of the study population is shown in Table 1. We observed that 67.7% of children had mothers under the age of 40, and 56% of them had fathers above the age of 40. Par-
ents had elementary or high school education (only 9.4% of children had mothers and 11.6% had fathers with university education). Positive family history of atopy was recorded in one-fifth of the participants. Two-thirds of study children were raised in small families (one child or two children). One-fifth of the study families had pets (a cat or dog), but only 14% of them had pets (a cat or dog) while their children were infants. Current contact with farm animals was reported for 16.9% of children, while 9.6% of children were in contact with farm animals in infancy. Families mostly used gas for cooking and wood for heating. According to residence, 59.5% of children lived in rural areas and 40.5% in urban areas (Table 2). At home, 54.1% of children were currently exposed to environmental tobacco smoke by any household member (Table 3).

Prevalence

The prevalence of allergic disorders is shown in Table 4. According to written questionnaire, wheezing during childhood was present in 383 (22.7%) children. Wheezing during previous 12 months was reported by 134 (7.9%) children, with significantly more wheezing in boys than girls (59.7% vs. 40.3%, p=0.02). The prevalence of diagnosed asthma was 4.1%, with significantly more boys than girls suffering from asthma (boys 63.2% vs. girls 36.8%, p=0.03).

The lifetime prevalence of rhinitis symptoms was 22.5%, while 325 (19.3%) children reported having the same nasal problems during the past 12 months. In 167 (9.9%) cases, nasal symptoms were associated with conjunctivitis. There was no gender difference in nasal symptoms. Itchy rash was reported by 301 (17.9%) children, with a lower prevalence of eczema symptoms during the previous 12 months (10.1%). Visible flexural dermatitis was recorded in 1.9% of study children.

The SPT participation rate was 48.1% (1070/2224). The prevalence of atopy was 20.2% (216 children had positive skin prick test for at least one of the allergens used), with house dust mite sensitization being the most frequent one (146/1070, 13.6%). The prevalence of atopic wheeze (defined as current wheeze plus SPT reactivity) was 3%.

Risk factors for current wheezing

The risk factors for current wheezing were male gender, environmental tobacco smoke exposure now and during early life, family history of atopy, atopy, SPT positive for *D. pteronyssinus*, grass and ragweed (Table 5). Symptoms of rhinoconjunctivitis and eczema were risk factors for wheezing over the last 12 months. Parental education, place of birth and place of residence, events in perinatal and infant periods (weight at birth, term of birth, breastfeeding, attending a child care or kindergarten), home environment and surrounding area (urban/rural, contact with furry pets and farm animals, damp spots, moulds or fungus on the walls, and fuel used for cooking and heating) were not associated with asthma.

Risk factors for current rhinoconjunctivitis

We observed significant association between current rhinoconjunctivitis and family history of allergic disorders and atopy. Positive SPT for *D. pteronyssinus*, ragweed and birch increased, while the influence of ru-

*n = number of participants with valid answer

rual setting in the 1st year of life reduced the risk of current rhinoconjunctivitis. Wheezing and eczema were strongly associated with current nasal and eye symptoms (Table 6).

Risk factors for current eczema

Current eczema was significantly higher among girls compared to boys. Family history of atopy increased the risk of eczema, which was even greater if the mother also suffered from an allergic disease. We observed significant associations of current eczema with positive SPT for *D. pteronyssinus*, wheezing and rhinitis (Table 6).

Discussion

The results of our study (within the context of ISAAC Phase II) contribute to previously published
Table 4. Prevalence of wheezing, rhinitis, rhinoconjunctivitis and eczema

| Symptoms of allergic disease | Sample (N) | Positive answer (n) | Prevalence |

SPT = skin prick test; D. pteronyssinus = Dermatophagoides pteronyssinus

data on the prevalence of asthma and allergic disease in childhood. Lifetime prevalence of wheezing, rhinitis symptoms and eczema symptoms was 22.7%, 22.5% and 17.8%, respectively. Period prevalence in the last 12 months was 7.9% for attacks of wheezing or whistling in the chest, 19.3% for rhinitis, 9.9% for rhinoconjunctivitis symptoms, and 10.0% for eczema symptoms. In addition, we assessed the prevalence of atopic sensitization and risk factors for the symptoms of allergic disease for the first time in Croatian schoolchildren. Among SPT tested children, 216 (20.2%) had positive reaction to at least one of the allergens used, with house dust mite sensitization being the most frequent one. The percentage of SPT results for each allergen was as follows: D. pteronyssinus 13.6%, ragweed 7.3%, grass 4.9%, dog 2.6%, birch 2.2%, egg 1.8%, cat 1.6%, and peanut 1.6%. The strongest risk factors for current wheezing were specific sensitization to D. pteronyssinus and current eczema. Also, positive SPT to ragweed increased the risk of asthma. Sensitization to grass and atopy contributed to fourfold increase in the risk of current wheezing. Environmental tobacco smoke, especially during infancy, family history of atopy, rhinitis, current rhinoconjunctivitis, and male gender were independent risk factors for wheezing in the past 12 months.

Positive SPT for pollen (ragweed and birch) was the strongest risk factor for current rhinoconjunctivitis. Also, family history of allergic disorders, atopy, positive SPT for D. pteronyssinus, wheezing (current and ever) and eczema increased the risk, while rural setting in infancy reduced the risk of current nasal and eye symptoms.

The strongest risk factors for current eczema included allergic diseases, rhinitis and wheezing. We also found an increased risk in girls, and in children with family history of atopy and specific sensitization to D. pteronyssinus.

The design of our study was cross sectional. We used the methodology of ISAAC Phase II using a standardized written questionnaire of self-reported symptoms. The recommended sample size was 3000 to ensure good prevalence estimates for severe asthma, but centers like the one in Brod-Posavina County with a small number of inhabitants were also included in ISAAC. We did not use video questionnaire. Data on environmental exposures such as environmental tobacco smoke exposure were assessed by a questionnaire rather than by objective measurement (e.g., cotinine) and collected retrospectively, which may affect real exposure. Also, environmental exposures may be influenced by behavior and affection status of parents towards the children included.

The prevalence of asthma and allergic disease dramatically increased in the second half of the 20th century. Data showing the increase in asthma prevalence among Croatian children were collected in a similar manner as data from the whole world in the same period (using surveys with non-standardized methodologies)\textsuperscript{11}. Over the last two decades, several standardized epidemiologic surveys (using ISAAC Phase I...
written and video questionnaire and Phase II written questionnaire) were conducted in different Croatian counties\textsuperscript{11-13,15}. They included different age groups of children: 6-7 years, 10-11 years, 12-14 and 14-16 years. In comparison to the research conducted in Zagreb\textsuperscript{15}, Primorje-Gorski Kotar County\textsuperscript{11} and Međimurje County\textsuperscript{13}, we recorded a higher prevalence of current wheezing (Brod-Posavina County 7.9%) as compared with Zagreb (6.02%) and Međimurje County (5.11%), but lower than in Primorje-Gorski Kotar County (6-7 age group 9.7% and 13-14 age group 8.4%) and Split-Dalmatia County (9.7%)\textsuperscript{12}. The prevalence of rhinoconjunctivitis was higher in Zagreb (12.13%), than in this (Brod-Posavina County 9.9%) and other Croatian studies (Međimurje County 7.14% and Primorje-Gorski Kotar County – 6-7 age group 5.6% and 13-14 age group 6.7%). Eczema was most prevalent in Brod-Posavina County (10.1%), compared to another three studies (Zagreb 6.1%, Međimurje County 5.34%, and Primorje-Gorski Kotar County – 6-7 age group 6.1% and 13-14 age group 4.8%). According to the results of previous Croatian studies, the authors recorded different prevalence of asthma and allergic disease in various regions. That could have been influenced by different geographic location, climate, diet, vegetation and socioeconomic factors. ISAAC reports show wide variability in the prevalence of allergic diseases, not just among regions but also among centers within the same county. Prevalence rates did not correlate with economic status, altitude and air pollution. The great variability observed has also suggested an important role of individual exposures and lifestyle, as well as of genetic background\textsuperscript{20}. According to data from different parts of Croatia, moderate prevalence rates of asthma, rhinoconjunctivitis and eczema were observed among Croatian schoolchildren in the period from 2005 to 2011, whereas a recent study revealed a further rising trend\textsuperscript{10}. Atopic sensitization has long been known to be related to childhood asthma\textsuperscript{21}. ISAAC Phase II investi-
gated the prevalence of atopic sensitization and its role in asthma. It included 54,439 children from 22 countries, of which 31,759 underwent SPT. The prevalence of SPT reactivity was lowest in Kintampo, rural Ghana (1.7%) and highest in Hong Kong, China (45.3%). There was no correlation of the prevalence of current wheeze and atopic sensitization with gross national income (GNI). However, researchers observed that associations between atopic sensitization and asthma symptoms increased with economic development. The prevalence of atopy was 20.2%. SPT positive for at least one of the allergens used was a strong risk factor for current wheeze and symptoms of rhinoconjunctivitis. Croatia, located in Central Europe, had GNI of 19,731 US$ per capita. The prevalence of atopy in countries with similar GNI per capita, such as Estonia, Turkey, and Latvia.

Recent research has shown that the relationship between allergen exposure, atopy and asthma is not clear. Atopy and asthma are not single phenotypes. Allergen exposures in the interaction with other environmental exposures had different outcomes on atopy and asthma phenotypes, depending on individual genetic background. We observed the importance of asthma heredity in our research. Family history of atopy, especially atopic mothers, increased the risk of asthma in their offspring. Asthma was more common among boys than girls, which might be explained by anatomic differences of lungs in preschool period. Environmental exposures such as allergens and specific sensitization may play an important role in particular asthma phenotypes. SPT reactivity to indoor (D. pteronyssinus) and outdoor (grass, ragweed) allergens increased the risk of asthma in our study group. Tobacco smoke is the most prevalent indoor pollutant. It is estimated that half the children worldwide are exposed to second-hand smoke. In utero and childhood exposure to environmental tobacco smoke is associated with an impaired lung function and is a risk factor for development of asthma. In our study population, tobacco smoke exposure by the mother was recorded in 19.3% of the children in utero and 30.7% of the children during the 1st year of life. According to different cross-sectional studies, the prevalence of mothers that smoke during pregnancy varies among different populations (4.4%–28.7%). In our study, children exposed to environmental tobacco smoke in infancy had two-fold greater risk of asthma. Our results are consistent with the observation that environmental tobacco smoke exposure in early life by the mother (mother smoking during pregnancy and 1st year of life) is associated with impaired lung function and constitutes a risk factor for development of asthma.

Modern diet characterized by an increased consumption of meat and fast food has been suggested to be a risk factor for asthma. However, we found no significant association between diet and asthma symptoms (low frequency of fast food consumption in our study population). Rhinoconjunctivitis was strongly associated with family history of allergic disease, whereas sensitization to D. pteronyssinus, ragweed and birch increased the risk of nasal symptoms. In addition, we observed a protective effect of rural setting in early life on current rhinoconjunctivitis symptoms. Previous studies have concluded that growing up in rural environment (through contact with farm animals, stables, endotoxin, and consumption of unpasteurized milk, more pets and siblings) reduces the prevalence of atopy, hay fever and asthma.

Interaction between susceptibility genes, environment and immune factors contributes to the pathogenesis of eczema. Heredity is complex and includes mutations in a number of genes (genes of skin barrier and genes of innate and adaptive immunity). In this study, family history of atopic disease and female gender increased the risk of eczema. Croatian authors from Međimurje analyzed the risk factors for development of atopic dermatitis in children. Their results, as well as the results from other epidemiologic studies, are consistent with our conclusion. Mutation in skin barrier genes impairs skin integrity and reduces resistance to external influences. Damaged skin facilitates penetration of allergens and contributes to the development of sensitization to Aeroallergens. This might explain the higher proportion of SPT positive for D. pteronyssinus among children with eczema in our study.

The symptoms of rhinitis and wheezing ever during childhood and during the study period increased the risk of atopic dermatitis in the current study. This is consistent with the majority of epidemiologic studies at the population level, which link allergic disease through the ‘atopic march’. However, research on the heterogeneity of allergic disease at the individual level has shown that concurrence of eczema, rhinitis and asthma is characteristic of only one distinct phenotype.
Conclusion

We found a moderate prevalence of allergic disease and atopy among Croatian schoolchildren. The risk factors for allergic disease in our study population included allergic disease in family, atopy, sensitization to indoor and outdoor allergens, and environmental tobacco smoke exposure. The findings from this epidemiologic survey provide a basis for further studies, which would bring better understanding of factors associated with allergic disease in childhood and enable novel public health intervention to reduce the prevalence of asthma.

Sažetak

ALERGIJSKE BOLESTI I ATOPIJA MEĐU ŠKOLSKOM DJECOM U ISTOČNOJ HRVATSKOJ

N. Aberle, B. Kljačić Bukvić, M. Blekić, M. Vučković, D. Bardak, A. Gudelj, G. Čančarević i M. Franić

Cilj je bio istražiti učestalost alergijskih bolesti i atopije u dječjoj dobi na području Brodsko-posavskog županija, moguće etiološke činitelje alergijskih bolesti te usporediti dobivene rezultate s rezultatima istraživača koji su rabili iste metode u Hrvatskoj i u svijetu. Istraživanje je obuhvatilo 1687 školske djece u dobi od 10-11 godina. Primijenjen je standardizirani upitnik Međunarodnog istraživanja o astmi i alergijama u dječjoj dobi za procjenu učestalosti alergijskih bolesti. Ispitnicima za koje smo dobili pismenu suglasnost roditelja učinjen je kožni ubodni test na inhalacijske i nutritivne alergene. Tijekom djetinjstva bronhoopstrukcije je prijavilo 22,7%, simptome rinitisa 22,5%, a simptome atopijskog dermatitisa 17,8% ispitanika. Učestalost alergijskih bolesti u posljednjih 12 mjeseci iznosila je 7,9% za bronhoopstrukciju, 9,9% za simptome rinitisa, 22,5% a simptome atopijskog dermatitisa 17,8% ispitanika. Učestalost alergijskih bolesti u posljednjih 12 mjeseci iznosila je 7,9% za bronhoopstrukciju, 9,9% za simptome atopijskog dermatitisa. Kožni test učinjen je u skupini od 1070 (63.5%) djece, od kojih je 20,2% imalo pozitivan kožni test na najmanje jedan od primijenjenih alergena, s najčešćom senzibilizacijom na alergene grine. Istraživanjem rizičnih činitelja uočeno je kako alergijske bolesti u obitelji, alergijska senzibilizacija i izloženost duhanskom dimu povećavaju rizik za alergijske bolesti u dječjoj dobi. Usporedbom s drugim međunarodnim centrima Brodsko-posavskog županija se svrstava u područja s umjerenom učestalošću alergijskih bolesti i atopije u dječjoj dobi.
