(Dated: April 15, 2022)

We propose a quantum-classical hybrid scheme for implementing the nonunitary Gutzwiller factor using a discrete Hubbard-Stratonovich transformation, which allows us to express the Gutzwiller factor as a linear combination of unitary operators involving only single-qubit rotations, at the cost of the sum over the auxiliary fields. To perform the sum over the auxiliary fields, we introduce two approaches that have complementary features. The first approach employs a linear-combination-of-unitaries circuit, which enables one to probabilistically prepare the Gutzwiller wave function on a quantum computer, while the second approach uses importance sampling to estimate observables stochastically, similar to a quantum Monte Carlo method in classical computation. The proposed scheme is demonstrated with numerical simulations for the half-filled Fermi-Hubbard model. Furthermore, we perform quantum simulations using a real quantum device, demonstrating that the proposed scheme can reproduce the exact ground-state energy of the two-site Fermi-Hubbard model within error bars.

I. INTRODUCTION

Solving quantum many-body systems directly using classical computers requires exponentially large computational resources that are often beyond the feasibility of current high-performance computing facilities. To overcome this difficulty, at least in part, a tremendous amount of effort has been devoted so far and several theoretical and numerical techniques have been successfully developed [1]. It should also be pointed out that, as one of the next-generation computing paradigms, quantum computing [2] has attracted growing interest for solving quantum many-body systems, which is becoming realistic, evidenced by the recent technological advances [3–12]. In this regards, the variational-quantum-eigensolver method and its variants have been proposed and demonstrated for computing ground-state [13–23] and low-lying excited-state [24–29] properties of quantum-many-body systems by exploiting noisy intermediate-scale quantum (NISQ) [30] computers and classical computers in a hybrid manner. For recent reviews on variational quantum algorithms, see for example Refs. [31–34]. It is also remarkable that physically motivated wave function such as Gutzwiller- and Jastrow-type wave functions [20] and a resonating-valence-bond-type wave function [35] have been implemented with NISQ computers.

The Gutzwiller wave function is known as a variational state for quantum-many-body systems in condensed matter physics that allows us to take into account electron correlation effects beyond the level of a single Slater-determinant state [36]. Despite its formal simplicity, the Gutzwiller-type wave functions, including Gutzwiller-projected Fermi-sea states [37], Gutzwiller-projected BCS states [38, 39], and Gutzwiller-projected Hartree-Fock states [40], can describe ground and low-lying excited states of several quantum many-body systems such as a lattice model of dimers [41], the Haldane-Shastry model [42, 43], and t-J-type models [44–50] (for a recent ground-state phase diagram of the t-t′-J model using the density-matrix-renormalization-group method, see Ref. [51]) qualitatively or even exactly in some particular cases.

In classical computation, the Gutzwiller wave function can be implemented rather straightforwardly when the Gutzwiller factor is diagonal in a computational basis. In quantum computation, one can also choose the computational basis states so that the Gutzwiller factor is diagonal. However, implementing a Gutzwiller-type wave function on a quantum computer is not straightforward due to its nonunitarity, and several schemes for implementing it have been developed [20, 52, 53]. Mazzola et al. [20] evaluates the expectation value of energy with respect to a Jastrow-type wave function [54, 55] by measuring the transformed Hamiltonian \( \hat{P}_t \hat{H} \hat{P}_t \) and the squared Jastrow factor \( (\hat{P}_t)^2 \) with a suitably truncated expansion of the Jastrow factor \( \hat{P}_t \). Murta and Fernández-Rossier [53] proposed a quantum circuit for probabilistically preparing the Gutzwiller wave function using ancillary qubits. It is also noteworthy that, aside from the Gutzwiller wave function, general frameworks for probabilistically performing nonunitary operations on a quantum computer have been proposed [56–58].

In this paper, we propose another scheme for implementing the Gutzwiller wave function using a discrete version [59] of the Hubbard-Stratonovich transformation [60], which allows us to represent the Gutzwiller factor as a linear combination of unitary operators, at the expense of introducing the auxiliary fields. In order to sum all the auxiliary fields, we introduce two different but complimentary approaches based on (i) a quantum circuit for the linear combination of unitary operators and (ii) an importance sampling technique. Furthermore, the proposed scheme is demonstrated using numerical simulations as well as a real quantum device.

The rest of this paper is organized as follows. In Sec. II, we provide formalism of the proposed scheme. We first define the Hamiltonian of the Fermi-Hubbard model and the Gutzwiller wave function. Then we describe the discrete Hubbard-
Stratonovich transformation for the Gutzwiller factor, and introduce the Jordan-Wigner transformation to construct concrete quantum circuits for implementing the Gutzwiller wave function on a quantum computer. In Sec. III, we describe two complementary approaches for performing the sum over the auxiliary fields. The first approach employs a linear combination of unitaries circuit for probabilistically preparing the Gutzwiller wave function on a quantum computer. The second approach uses an importance sampling technique to stochastically evaluate observables with respect to the Gutzwiller wave function. We also describe a simplification scheme that is applicable when the trial state is a separable state with respect to the spin degrees of freedom. The two approaches are demonstrated by numerical simulations for the ground state with respect to the spin degrees of freedom. The two approaches are demonstrated by numerical simulations for the Gutzwiller wave function. We also describe a simplification scheme that is applicable when the trial state is a separable state with respect to the spin degrees of freedom.

II. MODEL AND FORMALISM

A. Fermi-Hubbard model

We consider the Fermi-Hubbard model defined by the Hamiltonian

\[ \hat{H} = \hat{K} + U \hat{D}, \]

where

\[ \hat{K} = -J \sum_{\sigma=\uparrow,\downarrow} \sum_{\langle i,j \rangle} (\hat{c}_{i\sigma}^{\dagger} \hat{c}_{j\sigma} + \text{H.c.}) \]

and

\[ \hat{D} = \sum_{i=1}^{N_{\text{site}}} (\hat{n}_{i\uparrow} - \frac{1}{2})(\hat{n}_{i\downarrow} - \frac{1}{2}). \]

Here, \( J \) is the hopping parameter, \( U \) is the interaction parameter, \( N_{\text{site}} \) is the number of sites, and \( \hat{c}_{i\sigma}^{\dagger} \) (\( \hat{c}_{i\sigma} \)) is the creation (annihilation) operator of a fermion at site \( i (= 1, 2, \cdots, N_{\text{site}}) \) with spin \( \sigma (= \uparrow, \downarrow) \). The summation \( \sum_{\langle i,j \rangle} \cdots \) denotes the sum over all pairs of nearest-neighbor sites \( i \) and \( j \). \( \hat{n}_{i\sigma} = \hat{c}_{i\sigma}^{\dagger} \hat{c}_{i\sigma} \) is the fermion number operator at site \( i \) with spin \( \sigma \). In this study, we assume \( J > 0 \) and \( U \geq 0 \).

B. Gutzwiller wave function

The Gutzwiller wave function

\[ |\psi_g\rangle \equiv \frac{e^{-g\hat{D}}|\psi_0\rangle}{\sqrt{\langle\psi_0|e^{-2g\hat{D}}|\psi_0\rangle}}, \]

is known as a variational state for the Fermi-Hubbard model [36]. Here, \( e^{-g\hat{D}} \) is the Gutzwiller factor with \( 0 \leq g < \infty \) being the dimensionless variational parameter that penalizes the double occupancy of fermions at the same site, and \( |\psi_0\rangle \) is a trial state. In this study, we assume that \( |\psi_0\rangle \) is normalized as \( \langle\psi_0|\psi_0\rangle = 1 \) and it is an eigenstate of the total particle-number operator \( \hat{N} \equiv \sum_i \hat{n}_{i\uparrow} + \hat{n}_{i\downarrow} \). Since \( \langle\hat{N}, \hat{D}\rangle \equiv \hat{N}\hat{D} - \hat{D}\hat{N} = 0, |\psi_g\rangle \) is also an eigenstate of \( \hat{N} \). Typically, the trial state \( |\psi_0\rangle \) is chosen as a single Slater-determinant state such as the ground state of \( \hat{K} \) or a single-particle mean-field Hamiltonian. The Gutzwiller wave function \( |\psi_g\rangle \) can take into account electron correlation effects beyond the trial state \( |\psi_0\rangle \).

There is one remark on the Gutzwiller factor. Originally, the Gutzwiller factor was introduced in the following form [36]

\[ \hat{G}(g) \equiv \prod_{i=1}^{N_{\text{site}}} (1 - \hat{n}_{i\uparrow} \hat{n}_{i\downarrow}^\dagger) - e^{-g} \hat{D} = \hat{G}(g) \]

where \( 0 \leq g \leq 1 \) is the variational parameter and the right-hand side is valid for \( g \neq 0 \). If \( g = 0 \), \( \hat{G}(0) = \prod_{i=1}^{N_{\text{site}}} (1 - \hat{n}_{i\uparrow} \hat{n}_{i\downarrow}^\dagger) \), which excludes fermion configurations with doubly occupied sites from \( |\psi_0\rangle \), and \( \hat{G}(0) \) is called the Gutzwiller projector [61]. Provided that \( |\psi_0\rangle \) is an eigenstate of the total particle-number operator \( \hat{N} \), we can easily show that the following equality holds:

\[ |\psi_g\rangle = \frac{e^{-g\hat{D}}|\psi_0\rangle}{\sqrt{\langle\psi_0|e^{-2g\hat{D}}|\psi_0\rangle}} = \sqrt{\hat{G}(g)}|\psi_0\rangle \]

with the parameters \( g \) and \( g \) satisfying the relation (see, e.g., Ref. [62])

\[ g = e^{-g}. \]

Therefore, using \( e^{-g\hat{D}} \) is equivalent to using \( \hat{G}(g) \) for expressing the Gutzwiller wave function \( |\psi_g\rangle \), despite that \( e^{-g\hat{D}} \neq \hat{G}(g) \). The reason why we use \( e^{-g\hat{D}} \) is simply because \( e^{-g\hat{D}} \) is readily compatible with the Hubbard-Stratonovich transformation, as described in the next section.

C. Discrete Hubbard-Stratonovich transformation

To express the Gutzwiller factor \( e^{-g\hat{D}} \) as a linear combination of unitary operators, we introduce the discrete Hubbard-Stratonovich transformation [59]

\[ e^{-g(\hat{n}_{i\uparrow} - \frac{1}{2})(\hat{n}_{i\downarrow} - \frac{1}{2})} = \sum_{s_{i\uparrow}=\pm} e^{i s_{i\uparrow}} (\hat{n}_{i\uparrow} + \hat{n}_{i\downarrow} - 1), \]
where $s_i (= \pm 1)$ is the discrete auxiliary field, $\gamma = e^{\pi/4}/2$, and
$$\alpha = \arccos \left( e^{-\pi/2} \right).$$

Since the fermion number operators commute with each other, $[\hat{n}_{i\sigma}, \hat{n}_{j\pi}] = 0$, the Gutzwiller factor can be written simply as
$$e^{-\pi \hat{D}} = \gamma^{N_{aux}} \prod_{i=1}^{N_{site}} e^{2\pi i \hat{n}_i}$$
$$= \gamma^{N_{aux}} \prod_{i=1}^{N_{site}} (e^{2\pi i \hat{n}_i} + e^{-2\pi i \hat{n}_i}),$$
where
$$\hat{n}_i \equiv \frac{1}{2} (\hat{n}_{i\uparrow} + \hat{n}_{i\downarrow} - 1)$$
is introduced to simplify the notation. Now the nonunitary Gutzwiller factor [left-hand side of Eq. (11)] is expressed as a linear combination of unitary operators [right-hand side of Eq. (11)] after summing all the auxiliary fields $\{s_i\}_{i=1}^{N_{site}}$. The different decomposition schemes of the Hubbard-Stratonovich transformation that are potentially useful for other purposes are provided in Appendix A.

The expectation value of an operator $\hat{O}$ with respect to the Gutzwiller wave function $|\psi_g\rangle$ is given by
$$\langle \hat{O} \rangle = \frac{\langle \psi_0 | e^{-\pi \hat{D}} \hat{O} e^{\pi \hat{D}} | \psi_0 \rangle}{\langle \psi_0 | e^{2\pi i \hat{D}} | \psi_0 \rangle}$$
$$= \frac{\sum_s \langle \psi_0 | \prod_{i\in s} e^{2\pi i \hat{n}_i} \hat{O} \prod_{i\in s} e^{2\pi i \hat{n}_i} | \psi_0 \rangle}{\sum_s \langle \psi_0 | \prod_{i\in s} e^{2\pi i \hat{n}_i} | \psi_0 \rangle},$$
(12)
where
$$\sum_{s} \cdots = \prod_{s=1}^{N_{site}} \sum_{i\in s} \cdots$$
represents the sum over the auxiliary fields $\{s_i \in \{\pm 1\} \}_{s=1}^{N_{site}}$ with $N_r = 2$, implying that the total number of terms in the sum over $s$ is $2^{N_r \cdot N_{site}} = 4^{N_{site}}$. Notice that another label $r = 1, 2$ for the auxiliary fields introduced to distinguish the auxiliary fields corresponding to the bra and ket states, i.e., $r = 1$ for $|\psi_g\rangle$ and $r = 2$ for $|\psi_g\rangle$ [63].

### D. Jordan-Wigner transformation

The formalism described above is given in terms of the fermion operators. In order to implement the proposed scheme on a quantum computer, we now apply the Jordan-Wigner transformation of the form
$$\hat{c}_{i\sigma}^{\dagger} \equiv \frac{1}{2} \hat{X}_{i\sigma} - i \hat{Y}_{i\sigma} \prod_{k < i \sigma} \hat{Z}_k$$
and
$$\hat{c}_{i\sigma} = \frac{1}{2} \hat{X}_{i\sigma} + i \hat{Y}_{i\sigma} \prod_{k < i \sigma} \hat{Z}_k,$$
where $i, \cdots (1, 2, \cdots, 2N_{site})$ is the one-dimensional label for the site and spin indexes and $\hat{X}_i, \hat{Y}_i$, and $\hat{Z}_i$ are Pauli $X$, $Y$, and $Z$ operators acting on the $i$-th qubit. By $\equiv \cdots$ in Eqs. (16) and (17), we denote that the fermion operators on the left-hand side are expressed in terms of the Pauli operators under the Jordan-Wigner transformation.

Using the Jordan-Wigner transformation, the kinetic term in Eq. (2) and the interaction term in Eq. (3) of the Hamiltonian can be expressed with the Pauli operators as
$$\hat{K} \equiv -\frac{J}{2} \sum (i, j, \sigma) (\hat{X}_{i\sigma} \hat{X}_{j\sigma} + \hat{Y}_{i\sigma} \hat{Y}_{j\sigma}) \hat{Z}_{i\sigma} \hat{Z}_{j\sigma},$$
and
$$\hat{D} \equiv 1 \sum \hat{Z}_i \hat{Z}_i,$$
respectively, where $\hat{Z}_{i\sigma} j = \prod_{k < j} \hat{Z}_k$ is the Jordan-Wigner string for $i \leq k \leq j$ and $\hat{Z}_{i\sigma} j = \hat{I}$ (identity operator) for $i = j \pm 1$. Similarly, the operator $\hat{n}_i$ in Eq. (12) can be expressed as
$$\hat{n}_i \equiv -\frac{1}{4} (\hat{Z}_i + \hat{Z}_i^\dagger) \equiv \frac{1}{2} \begin{bmatrix} -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix},$$
where $\equiv$ denotes the matrix representation and the matrix here is represented with the computational basis states $|00\rangle \equiv |0\rangle_1 |0\rangle_2, |01\rangle \equiv |0\rangle_1 |1\rangle_2, |10\rangle \equiv |1\rangle_1 |0\rangle_2$, and $|11\rangle \equiv |1\rangle_1 |1\rangle_2$ with $\hat{Z}_i |0\rangle_1 = |0\rangle_1$ and $\hat{Z}_i |1\rangle_1 = -|1\rangle_1$. Finally, the rotation generated by $2\hat{n}_i$ can be expressed as a product of the one-qubit rotations, i.e.,
$$e^{2\pi i \hat{n}_i \cdot \alpha} \equiv \hat{R}_{Z_i}(\alpha) \otimes \hat{R}_{Z_i}(\alpha) \equiv \begin{bmatrix} e^{-i\alpha} & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & e^{i\alpha} \end{bmatrix},$$
where
$$\hat{R}_Z(\alpha) = \exp \left( -i \alpha \hat{Z}/2 \right).$$

Notice that $e^{2\pi i \hat{n}_i \cdot \alpha}$ acts nontrivially only on the empty state (corresponding to $|00\rangle$) and the doubly occupied state (corresponding to $|11\rangle$). Equation (21) shows that, under the Jordan-Wigner transformation, $e^{2\pi i \hat{n}_i \cdot \alpha}$ is expressed simply as a direct product of the single-qubit $Z$ rotation gates with the same rotation angle $\alpha$.

### III. SUM OVER AUXILIARY FIELDS

Since the terms involved in the sum over the auxiliary fields in Eqs. (10) and (14) increases exponentially in $N_{site}$, performing directly the sum becomes unfeasible as $N_{site}$ is large. Nevertheless, here we introduce two approaches, based on (i) a
quantum circuit for a linear combination of unitary operators and (ii) an importance sampling technique, for performing the sum over the auxiliary fields. These two approaches have complementary features.

The first approach based on a quantum circuit for a linear combination of unitary operators allows us to probabilistically prepare the Gutzwiller wave function |ψg⟩ on a quantum computer by using N\text{site} ancillary qubits, which can be trivially reduced to one if an ancillary qubit is reused, and 2N\text{site} controlled-RZ operations. However, the probability for successfully preparing the desired state decreases exponentially in N\text{site}. In the second approach based on an importance sampling technique, the expectation values of observables are evaluated stochastically by the importance sampling, instead of preparing the Gutzwiller wave function itself on a quantum computer. In general, this approach suffers from the sign problem (more precisely, the phase problem) as in the auxiliary-field quantum Monte Carlo method [64, 65].

### A. Linear combination of unitary operators

As shown in Eq. (11), summing all the auxiliary fields \( s_i = \pm 1 \) for \( i = 1, 2, \ldots, N\text{site} \), the nonunitary Gutzwiller factor \( e^{-\frac{gD}{2}} \) is expressed as a linear combination of \( 2^{N\text{site}} \) unitary operators, each of which is composed of a product of \( N\text{site} \) unitary operators \( e^{\pm 2\alpha \hat{\eta}_i} \). Under the Jordan-Wigner transformation, the unitary operator \( e^{\pm 2\alpha \hat{\eta}_i} \) is then simply represented as a direct product of two single-qubit Z rotation gates acting on qubits \( i \) and \( i \), as shown in Eq. (21).

In order to implement the linear combination of these unitary operators on a quantum computer, we can use a Hadamard-test-like variant [66] of the quantum circuit known as the linear combination of unitary operators [67, 68], shown in Figs. 1(a) and 1(b) for \( N\text{site} = 1 \) and \( N\text{site} = 2 \), respectively, as examples, which can be easily generalized to \( N\text{site} \geq 3 \). In these figures, we use \( N\text{site} \) ancillary qubits and measure each of them once. Instead, we can also consider the equivalent quantum circuit with only one ancillary qubit and every time after measuring it, we reuse this ancillary qubit repeatedly \( N\text{site} \) times. This can certainly reduce the total number of necessary qubits, but has to initialize a qubit during the computation.

Figure 1(c) shows another way to simplify the quantum circuits in Figs. 1(a) and 1(b). Namely, the consecutive opposite-conditional controlled-\( \hat{\eta}^\dagger \)-rotation gates with opposite rotation angles can be simplified by, for example, removing the “controlled” part from the first controlled-\( \hat{\eta}^\dagger \)-rotation gate and doubling the rotation angle in the second controlled-\( \hat{\eta}^\dagger \)-rotation gate. Such an operation can be implemented, under the Jordan-Wigner transformation, with 2 \( R_Z \) gates and 2 controlled-\( R_Z \) gates, instead of 4 controlled-\( R_Z \) gates, as shown in the lower part of Fig. 1(c). Following this strategy, the quantum circuit shown in Fig. 1(b) for \( N\text{site} = 2 \) is now explicitly given in Fig. 1(d). We note that this simplification strategy is applicable not only for a quantum circuit containing two consecutive controlled-\( \hat{\eta}^\dagger \)-rotation gates with opposite rotation angles but also for a quantum circuit containing two consecutive controlled-time-evolution operators with opposite evolution times, and hence the quantum circuit proposed for the quantum power method in Ref. [66] (and also a recent proposal for performing the imaginary-time evolution in Ref. [58]) can be simplified in the same manner.

If the measured states in the \( N\text{site} \) ancillary qubits are all found in the state |0⟩, then the desirable state \( \prod_{i=1}^{N\text{site}} \sum_{s_i=\pm} e^{\pm 2\alpha \hat{\eta}_i}\langle \psi_0 | \) is prepared in the rest of the qubits, i.e., in the 2\( N\text{site} \) register qubits, as shown in Fig. 1(d). After applying the second Hadamard gates on the ancillary qubits,
the state $|\Psi\rangle$ of the whole system (see Fig. 1) is given as

$$|\Psi\rangle = |00\cdots0\rangle \otimes \frac{1}{2^{N_{\text{site}}}} \prod_{i=1}^{N_{\text{site}}} (e^{2i\alpha_i^x} + e^{-2i\alpha_i^x})|\psi_0\rangle$$

+ (unwanted terms)

$$= |00\cdots0\rangle \otimes e^{-gN_{\text{site}}/4} e^{-2g\hat{D}}|\psi_0\rangle$$

+ (unwanted terms). \hspace{1cm} (23)

Here, $|00\cdots0\rangle$ denotes the product state of all the $N_{\text{site}}$ ancillary states being (0), and "(unwanted terms)" denotes the other $2^{N_{\text{site}}} - 1$ terms with the $N_{\text{site}}$ ancillary states being distinct from $|00\cdots0\rangle$, for which the Gutzwiller wave function $|\psi_g\rangle$ is not prepared in the register qubits. Note also that Eq. (11) is used in the second equality of Eq. (23). According to the Born rule, the probability for successfully preparing the desired state $|\psi_g\rangle$, denoted as $p_{00\cdots0}$, is given by

$$p_{00\cdots0} = \langle \Psi | \hat{P}_{00\cdots0} | \Psi \rangle = e^{-gN_{\text{site}}/2} \langle \psi_0 | e^{-2g\hat{D}} | \psi_0 \rangle,$$ \hspace{1cm} (24)

where $\hat{P}_{00\cdots0} = |00\cdots0\rangle\langle00\cdots0| \otimes I$ is the projection operator that projects a state in the whole Hilbert space onto the subspace associated with the result of the measurement observing that the state of the ancillary qubits is $|00\cdots0\rangle$. According to the projection postulate, the state after the corresponding (successful) measurement, denoted as $|\Psi_{\text{projected}}\rangle$, is then given by

$$|\Psi_{\text{projected}}\rangle = \frac{1}{\sqrt{p_{00\cdots0}}} \hat{P}_{00\cdots0} | \Psi \rangle = |00\cdots0\rangle \otimes |\psi_g\rangle,$$ \hspace{1cm} (25)

indicating that the Gutzwiller wave function $|\psi_g\rangle$ is prepared in the register qubits.

Figure 2 shows the success probability $p_{00\cdots0}$ as functions of $N_{\text{site}}$ and $g$ calculated numerically using a classical computer. Here, the trial state $|\psi_0\rangle$ is chosen as the ground state of $\hat{K}$ at half filling defined on the one-dimensional chain under open-boundary conditions. As clearly observed in Fig. 2(a), the success probability $p_{00\cdots0}$ decrease exponentially in $N_{\text{site}}$. In order to examine the $g$ dependence of $p_{00\cdots0}$, it is useful to study the logarithmic derivative of the success probability. It follows from Eq. (24) that the logarithmic derivative of the success probability, $\partial_g \ln p_{00\cdots0}$, is related to the expectation value of $\hat{D}$ via

$$\langle \psi_g | \hat{D} | \psi_g \rangle = \frac{1}{2} \alpha^x \ln \langle \psi_0 | e^{-2g\hat{D}} | \psi_0 \rangle$$

$$= - \left( \frac{N_{\text{site}}}{4} + \frac{1}{2} \frac{\partial}{\partial g} \ln p_{00\cdots0} \right).$$ \hspace{1cm} (26)

Since $\lim_{g \to 0} \langle \psi_g | \hat{D} | \psi_g \rangle = 0$ and $\lim_{g \to \infty} \langle \psi_g | \hat{D} | \psi_g \rangle = -N_{\text{site}}/4$ for the present choice of $|\psi_0\rangle$, the slopes of $\ln p_{00\cdots0}$ in the two limits are given respectively by

$$\lim_{g \to 0} \frac{\partial}{\partial g} \ln p_{00\cdots0} = - \frac{N_{\text{site}}}{2}$$ \hspace{1cm} (27)

and

$$\lim_{g \to \infty} \frac{\partial}{\partial g} \ln p_{00\cdots0} = 0.$$ \hspace{1cm} (28)

implying that $p_{00\cdots0}$ decreases exponentially in $g$ for small $g$, but the decrease saturates for large $g$, as indeed found in Fig. 2(b). A finite success probability in the limit $g \to \infty$ leaves a possibility of preparing the Gutzwiller-projected state [69] relevant for the t-J-type models [70–76] for a moderate $N_{\text{site}}$.

Despite the exponential decrease of the success probability in $N_{\text{site}}$, an advantage of the approach described here is that the Gutzwiller wave function $|\psi_g\rangle$ itself can be prepared on a quantum computer. In this sense, the present scheme is similar to that in the previous study [53], even though the two schemes take different routes: the quantum circuit in Ref. [53] is based on the original form of the Gutzwiller factor in Eq. (5) with a slightly different parametrization, whereas the quantum circuit in the present study is based on the Hubbard-Stratonovich-transformed Gutzwiller factor in Eq. (11). It should be emphasized that the quantum circuit proposed here is rather simpler than that proposed in the previous study [53]. This point will be further discussed in Sec. V.
B. Importance sampling

1. Reformulation and sampling

To perform the sum \( \sum_s \) over the auxiliary fields \( s \) in Eq. (14) stochastically using the Monte Carlo method, we rewrite Eq. (14) as

\[
\langle \hat{O} \rangle = \sum_s P_s \langle \hat{O} \rangle_s,
\]

(29)

where

\[
P_s \equiv \frac{\langle \psi_0 | \prod_{i=1}^{N_{\text{aux}}} e^{2\alpha x_i \hat{S}_z} \hat{O} \prod_{j=1}^{N_{\text{aux}}} e^{2\alpha x_j \hat{S}_z} | \psi_0 \rangle}{\sum_{s'} \langle \psi_0 | \prod_{i=1}^{N_{\text{aux}}} e^{2\alpha x_i \hat{S}_z} \hat{O} \prod_{j=1}^{N_{\text{aux}}} e^{2\alpha x_j \hat{S}_z} | \psi_0 \rangle}.
\]

(30)

and

\[
\langle \hat{O} \rangle_s \equiv \frac{\langle \psi_0 | \prod_{i=1}^{N_{\text{aux}}} e^{2\alpha x_i \hat{S}_z} \hat{O} \prod_{j=1}^{N_{\text{aux}}} e^{2\alpha x_j \hat{S}_z} | \psi_0 \rangle}{\langle \psi_0 | \prod_{i=1}^{N_{\text{aux}}} e^{2\alpha x_i \hat{S}_z} | \psi_0 \rangle}.
\]

(31)

Notice that \( P_s \) is in general complex and hence the method suffers from the phase problem, as in the auxiliary-field Monte Carlo method [64, 65]. In the presence of the phase problem, a proper modification in Eq. (29) is necessary (see for example Refs. [77–79]). In this study, however, we only consider cases satisfying that \( P_s \) is real and \( P_s > 0 \), i.e., in the absence of the phase problem (see Appendix B).

The auxiliary fields in Eq. (29) are sampled by the Metropolis-Hastings algorithm using the local update with an acceptance probability \( p(s \rightarrow s') = \min(1, P_{s'} / P_s) \) for accepting the move from \( s \) to \( s' \). In the local update, the candidate auxiliary fields \( s' = (s'_{i, \tau})_{i=1}^{N_{\text{aux}}} \) is chosen by flipping only a single auxiliary field, \( s_{i, \tau} \rightarrow -s_{i, \tau} \), among the current auxiliary fields \( s = (s_{i, \tau})_{i=1}^{N_{\text{aux}}} \) and the remaining auxiliary fields are unaltered. If the proposed move from \( s \) to \( s' \) is accepted, the candidate auxiliary fields \( s' \) are adopted as the new auxiliary fields for the next iteration. Otherwise, the old auxiliary fields \( s \) remain for the next iteration. Here, we select a flipped auxiliary field \( s_{i, \tau} \) in the candidate auxiliary fields \( s' \) sequentially for \( i = 1, 2, \ldots, N_{\text{aux}} \) and \( \tau = 1, 2 \), and define one Monte Carlo sweep when all the auxiliary fields are selected once in the Monte Carlo iterations. We measure observables every Monte Carlo sweep and denote the number of measurements by \( N_{\text{MC}} \). Note that we do not have to evaluate the denominator in Eq. (30) because only the ratio of \( P_{s'} / P_s \) is required in the Monte Carlo iterations.

Using the relation in Eq. (21) for \( \hat{\eta} \) under the Jordan-Wigner transformation, the numerator of \( P_s \) in Eq. (30) and the denominator of \( \langle \hat{O} \rangle_s \) in Eq. (31) can be expressed with the Pauli operators as

\[
\langle \psi_0 | \prod_{i=1}^{N_{\text{aux}}} e^{2\alpha x_i \hat{S}_z} \hat{O} \prod_{j=1}^{N_{\text{aux}}} e^{2\alpha x_j \hat{S}_z} | \psi_0 \rangle = \langle \psi_0 | \hat{\eta} \hat{\eta}^{\dagger} \hat{\eta} | \psi_0 \rangle.
\]

Therefore, as shown in Fig. 3(a), a quantum circuit for preparing the state \( \prod_{i=1}^{N_{\text{aux}}} e^{2\alpha x_i \hat{S}_z} \hat{\eta} \prod_{j=1}^{N_{\text{aux}}} e^{2\alpha x_j \hat{S}_z} | \psi_0 \rangle \) in the numerator of \( \langle \hat{O} \rangle_s \) in Eq. (31) is significantly simple. A quantum circuit for the state \( \prod_{i=1}^{N_{\text{aux}}} e^{2\alpha x_i \hat{S}_z} | \psi_0 \rangle \) in the denominator of \( \langle \hat{O} \rangle_s \) in Eq. (31) can be obtained by simply setting \( \hat{\eta} = \hat{1} \) and combining the two rotation gates \( \hat{R}_{Z_\alpha} (s_{1,1} \alpha) \) and \( \hat{R}_{Z_\alpha} (s_{1,2} \alpha) \) into the single rotation \( \hat{R}_{Z_\alpha} (s_{1,1} + s_{1,2} \alpha) \) in Fig. 3(a).

2. Simplification for spin-separable states

Next, we describe a simplification that can be applied when the trial state \( | \psi_0 \rangle \) is separable according to the decomposition of the Hilbert space \( \mathcal{V} = \mathcal{V}_1 \otimes \mathcal{V}_2 \), where \( \mathcal{V}_\tau \) denotes the
Hilbert space for fermions with spin $\sigma$. Let us assume that $|\psi_0\rangle$ is a separable state of the form

$$|\psi_0\rangle = |\psi_{0,\uparrow}\rangle \otimes |\psi_{0,\downarrow}\rangle,$$  \hspace{1cm} (34)

where $|\psi_{0,\sigma}\rangle \in \mathcal{V}_{\sigma}$, as in the case for the ground state of $\hat{\mathcal{K}}$. We refer to a state of the form in Eq. \(34\) as a spin-separable state.

Let us now introduce the following unitary operator

$$\hat{u}_{s,\sigma} \equiv \prod_{i=1}^{N_{\text{site}}} \frac{1}{\sqrt{Z_i}} e^{i\alpha_i \overline{\delta}_{\sigma}-\frac{i}{2}} \otimes \hat{R}_{Z_i}(s_i,\sigma)$$ \hspace{1cm} (35)

on $\mathcal{V}_{\sigma}$ for a given set of auxiliary fields $s_i,\sigma = \{s_i,\sigma\}_{i=1}^{N_{\text{site}}}$. The last equality is simply because $\hat{R}_{Z_i} \otimes \hat{I}$ under the Jordan-Wigner transformation. Then the product of unitary operators generated by $\hat{\eta}_i$ can be written as

$$\prod_{i=1}^{N_{\text{site}}} e^{2\pi i (\overline{\delta}_{\sigma} + \overline{\delta}_{\sigma}) \hat{\eta}_i} = \hat{u}_{s,\uparrow} \hat{u}_{s,\downarrow} \otimes \hat{u}_{s,\uparrow} \hat{u}_{s,\downarrow}.$$ \hspace{1cm} (36)

Therefore, $P_s$ and $\langle \hat{O} \rangle_s$ in Eqs. \(30\) and \(31\) are given respectively as

$$P_s = \frac{\langle \psi_{0,\uparrow} | \hat{u}_{s,\uparrow} \hat{u}_{s,\downarrow} | \psi_{0,\uparrow} \rangle \langle \psi_{0,\uparrow} | \hat{u}_{s,\uparrow} \hat{u}_{s,\downarrow} | \psi_{0,\downarrow} \rangle}{\sum_{\sigma} \langle \psi_{0,\uparrow} | \hat{u}_{s,\uparrow} \hat{u}_{s,\downarrow} | \psi_{0,\uparrow} \rangle \langle \psi_{0,\uparrow} | \hat{u}_{s,\uparrow} \hat{u}_{s,\downarrow} | \psi_{0,\downarrow} \rangle} \hspace{1cm} (37)$$

and

$$\langle \hat{O} \rangle_s = \frac{\langle \psi_{0,\uparrow} | \hat{u}_{s,\uparrow} \hat{u}_{s,\downarrow} \hat{O} \hat{u}_{s,\uparrow} \hat{u}_{s,\downarrow} | \psi_{0,\uparrow} \rangle \langle \psi_{0,\uparrow} | \hat{u}_{s,\uparrow} \hat{u}_{s,\downarrow} \hat{O} \hat{u}_{s,\uparrow} \hat{u}_{s,\downarrow} | \psi_{0,\downarrow} \rangle}{\langle \psi_{0,\uparrow} | \hat{u}_{s,\uparrow} \hat{u}_{s,\downarrow} | \psi_{0,\uparrow} \rangle \langle \psi_{0,\uparrow} | \hat{u}_{s,\uparrow} \hat{u}_{s,\downarrow} | \psi_{0,\downarrow} \rangle} \hspace{1cm} (38)$$

where the observable of the form

$$\hat{O} = \hat{O}_\uparrow \otimes \hat{O}_\downarrow$$ \hspace{1cm} (39)

is assumed. A quantum circuit for preparing the state $\prod_{i=1}^{N_{\text{site}}} e^{2\pi i (\overline{\delta}_{\sigma} + \overline{\delta}_{\sigma}) \hat{\eta}_i} |\psi_0\rangle$ in the numerator of $\langle \hat{O} \rangle_s$ in Eq. \(31\) is now further simplified as shown in Fig. 3(b). A quantum circuit for the state $\prod_{i=1}^{N_{\text{site}}} e^{2\pi i (\overline{\delta}_{\sigma} + \overline{\delta}_{\sigma}) \hat{\eta}_i} |\psi_0\rangle$ in the denominator of $\langle \hat{O} \rangle_s$ in Eq. \(31\) can be obtained by simply setting $\hat{O} = \hat{I}$ and combining two consecutive rotations into one in Fig. 3(b). Notice that when $|\psi_0\rangle$ is a spin-separable state, only $N_{\text{site}}$ qubits are required at a time.

Finally, we note that since the kinetic term of the Hamiltonian has the form,$$
\hat{K} = \hat{K}_\uparrow \otimes \hat{I} + \hat{I} \otimes \hat{K}_\downarrow,$$ \hspace{1cm} (40)

where $\hat{K}_\sigma$ is the summand of $\sum_{\sigma}$ in Eq. (2), $\langle \hat{K} \rangle_s$ can be written simply as

$$\langle \hat{K} \rangle_s = \frac{\langle \psi_{0,\uparrow} | \hat{u}_{s,\uparrow} \hat{K}_\uparrow \hat{u}_{s,\downarrow} | \psi_{0,\uparrow} \rangle \langle \psi_{0,\uparrow} | \hat{u}_{s,\uparrow} \hat{K}_\uparrow \hat{u}_{s,\downarrow} | \psi_{0,\downarrow} \rangle}{\langle \psi_{0,\uparrow} | \hat{u}_{s,\uparrow} \hat{u}_{s,\downarrow} | \psi_{0,\uparrow} \rangle \langle \psi_{0,\uparrow} | \hat{u}_{s,\uparrow} \hat{u}_{s,\downarrow} | \psi_{0,\downarrow} \rangle} + \frac{\langle \psi_{0,\downarrow} | \hat{u}_{s,\uparrow} \hat{K}_\downarrow \hat{u}_{s,\downarrow} | \psi_{0,\uparrow} \rangle \langle \psi_{0,\downarrow} | \hat{u}_{s,\uparrow} \hat{K}_\downarrow \hat{u}_{s,\downarrow} | \psi_{0,\downarrow} \rangle}{\langle \psi_{0,\uparrow} | \hat{u}_{s,\uparrow} \hat{u}_{s,\downarrow} | \psi_{0,\uparrow} \rangle \langle \psi_{0,\uparrow} | \hat{u}_{s,\uparrow} \hat{u}_{s,\downarrow} | \psi_{0,\downarrow} \rangle}.$$ \hspace{1cm} (41)

A similar formula is also obtained for $\langle \hat{D} \rangle_s$.
FIG. 4. The expectation values of (a, d, g) the total energy $E$, (b, e, h) the kinetic energy $\langle \hat{K} \rangle$, and (c, f, i) the potential energy $U(\hat{D})$ as a function of the Gutzwiller parameter $g$ for the Fermi-Hubbard model at half filling with $U/J = 1, 2, 3, 4$ (top to bottom). The models studied here are on (a-c) a 4 x 2 ladder lattice, (d-f) a 10-site one-dimensional lattice, and (g-i) a 12-site one-dimensional lattice under open-boundary conditions. The number $N_{MC}$ of Monte Carlo samplings is indicated in the figure. For comparison, the exact results are also plotted by solid lines. In addition, the results obtained by fully summing all the auxiliary fields are shown by open symbols. Note that $\langle \hat{K} \rangle$ does not depend on the value of $U$. The results of $\langle \hat{K} \rangle$ for two different $N_{MC}$ values and obtained by fully summing all the auxiliary fields are indistinguishable in this scale.

the following state with two fermions occupying the bonding orbital:

$$|\psi_0\rangle = \frac{1}{2} \left( |\uparrow\downarrow\rangle + |\downarrow\uparrow\rangle \right) \left( |\uparrow\rangle + |\downarrow\rangle \right) \langle \text{vac} \rangle.$$  \hspace{1cm} (42)

A straightforward calculation shows that $\langle \psi_0 | e^{-\hat{D}^\dagger \hat{D}} \psi_0 \rangle = -2J$, $\langle \psi_0 | e^{-2\hat{D}^\dagger \hat{D}} \psi_0 \rangle = \cosh g$, and

$$\langle \psi_0 | e^{-\hat{D}^\dagger \hat{D}} \psi_0 \rangle = -\frac{1}{2} \partial_g \langle \psi_0 | e^{-2\hat{D}^\dagger \hat{D}} \psi_0 \rangle = -\frac{1}{2} \sinh g.$$  \hspace{1cm} (43)

Therefore, the total energy $E(g)$ is given by

$$E(g) = \langle \hat{K} \rangle + U(\hat{D})$$

$$= -\frac{1}{2} \frac{\cosh g}{2J + U/2 \sinh g}.$$  \hspace{1cm} (43)

Considering $E(g)$ as the variational energy, the stationary condition $\partial E(g)/\partial g |_{g=g_{opt}} = 0$ gives us the optimal variational parameter $g_{opt}$ such that

$$\sinh g_{opt} = \frac{U}{4J}.$$  \hspace{1cm} (44)

or equivalently $g_{opt} = \ln \left( \frac{U}{4J} + \sqrt{\left( \frac{U}{4J} \right)^2 + 1} \right)$. By substituting Eq. (44) into Eq. (43), the optimized variational energy is obtained as

$$E(g_{opt}) = -\sqrt{4J^2 + \frac{U^2}{4}},$$  \hspace{1cm} (45)

which coincides with the exact ground-state energy of the two-site Fermi-Hubbard model at half filling, implying that the Gutzwiller wave function $|\psi_g\rangle$ with $g = g_{opt}$ is the exact
ground state of the two-site Fermi-Hubbard model at half filling.

B. Quantum simulations

Using a real quantum device, we shall now evaluate the expectation values of the total energy $E$, the kinetic energy $\langle \hat{K} \rangle$, and the potential energy $U(\hat{D})$ with respect to the Gutzwiller wave function $|\psi_r\rangle$ for the two-site Fermi-Hubbard model at half filling. Under the Jordan-Wigner transformation, the fermion vacuum is expressed as $|\text{vac}\rangle \overset{\text{JWT}}{=} |0\rangle_1 |0\rangle_2 |0\rangle_1 |0\rangle_2$, and hence $|\psi_0\rangle$ in Eq. (42), i.e., the ground state of $\hat{K}$, is given by $|\psi_0\rangle = |\psi_{0,1}\rangle \otimes |\psi_{0,2}\rangle$ with

$$|\psi_{0,\sigma}\rangle = \frac{1}{\sqrt{2}} \left( |0\rangle_1 \sigma \langle 1| \sigma + |1\rangle_1 |0\rangle_2 \right).$$

(46)

This state $|\psi_{0,\sigma}\rangle$ is merely one of the Bell states and is easily prepared as

$$|\psi_{0,\sigma}\rangle = \bar{C} \bar{X} \left( \hat{H} \otimes \hat{X} \right) |0\rangle_1 |0\rangle_2,$$

(47)

where $\bar{X}$, $\bar{H}$ and $\bar{C} \bar{X}$ denote the gate operations for Pauli X, Hadamard, and controlled-X (CNOT) gates, respectively. As discussed in Sec. III B 2, for the spin-separable trial state $|\psi_0\rangle$, the numerator of Eq. (14) is expressed as

$$\langle \psi_0 | e^{-\hat{D}} \hat{O}_1 \otimes \hat{O}_2 e^{-\hat{D}} | \psi_0 \rangle = \gamma^4 \prod_{\sigma = \uparrow, \downarrow} P^{\sigma}_{x\sigma}(g),$$

(48)

with

$$P^{\sigma}_{x\sigma}(g) \equiv \langle \psi_{0,\sigma} | \hat{u}_{1,\sigma} \hat{O}_1 \hat{u}_{2,\sigma} | \psi_{0,\sigma} \rangle,$$

(49)

where $\hat{O}_\sigma = \hat{O}_1 \hat{O}_2$ and $\hat{u}_{1,\sigma} = (\hat{I}_\sigma, \hat{X}_\sigma, \hat{Y}_\sigma, \hat{Z}_\sigma)$. Here, $\hat{I}_\sigma$ is the identity operator acting on the $\hat{c}_\sigma$ qubit. Noticing that $\hat{u}_{1,\sigma} \neq \hat{u}_{2,\sigma}$ in general, we can not use the direct measurement method to evaluate the expectation value of Eq. (49), at least in a simple way [84]. Alternatively, we exploit the Hadamard test to measure the expectation value of the unitary operator $\hat{u}_{1,\sigma} \hat{O}_1 \hat{u}_{2,\sigma}$ [85]. The specific form of the Hamiltonian for the two-site Fermi-Hubbard model is simply given by $\hat{H} = \hat{K} + \hat{U} \hat{D}$ with $\hat{K} \overset{\text{JWT}}{=} -\frac{i}{2} \sum_{\sigma = \uparrow, \downarrow} \left( \hat{X}_1 \hat{X}_2 + \hat{Y}_1 \hat{Y}_2 \right)$ and $\hat{D} \overset{\text{JWT}}{=} \frac{1}{2} \sum_{\sigma = \uparrow, \downarrow} \hat{Z}_1 \hat{Z}_2$. Therefore, it is sufficient to evaluate $P^{\uparrow\uparrow}_{\downarrow\downarrow}(g)$, $P^{\uparrow\downarrow}_{\downarrow\uparrow}(g)$, and $P^{XX}_{\downarrow\downarrow}(g)$ to calculate $\langle \hat{K} \rangle$ and $\langle \hat{D} \rangle$, and thereby the total energy $E$. Instead of employing the importance sampling, here we directly perform the sum over all the auxiliary fields, $\sum_{\ldots} \equiv \sum_{t_1 = \pm 1} \sum_{t_2 = \pm 1} \sum_{t_3 = \pm 1} \sum_{t_4 = \pm 1} \sum_{t_5 = \pm 1} \ldots$, because the total number of terms is only $2^4 = 16$.

Figure 5 shows the quantum circuits for estimating the expectation values $P^{\uparrow\uparrow}_{\downarrow\downarrow}(g)$, $P^{\uparrow\downarrow}_{\downarrow\uparrow}(g)$, and $P^{XX}_{\downarrow\downarrow}(g)$. Notice that here we explicitly introduce the SWAP operations in order to involve only two-qubit gates acting on neighboring qubits in these quantum circuits. To further simplify the quantum circuits, the second SWAP gate that would have primarily been placed after the last $Z$ rotation in each quantum circuit is omitted without affecting validity of the measurement. This latter simplification, yielding reduction of three CNOT gates, is beneficial for suppressing noise inherent to a real quantum device.

We implement the quantum circuits using the Quantum Information Software Kit (Qiskit) [86] and perform computations on the IBM Q Manila device (IBMq-Manila), the device publicly available through the IBM Quantum Lab platform [87]. We also run the same quantum circuits on the classical simulator (qasm_simulator), which is considered as an ideal quantum device, to realize the impact of noise. Each experiment runs 8192 shots to measure the local state at the ancillary qubit in the computational basis. The same set of experiments is repeated 16 times to evaluate the average and the standard deviation, the latter being the estimate of the statistical error.

Figure 6 shows the results for the denominator of Eq. (14) and the numerators for $\langle \hat{Z}_1 \hat{Z}_1 \rangle$ and $\langle \hat{X}_1 \hat{X}_2 \rangle$, which are calculated respectively as

$$\langle \psi_0 | e^{-2\hat{D}} | \psi_0 \rangle = \left( \sum_{g} P^{\uparrow\uparrow}_{\downarrow\downarrow}(g) \right)^2,$$

(50)

$$\langle \psi_0 | e^{-\hat{D}} \hat{Z}_1 \hat{Z}_1 e^{-\hat{D}} | \psi_0 \rangle = \left( \sum_{g} P^{\uparrow\downarrow}_{\downarrow\uparrow}(g) \right)^2,$$

(51)

and

$$\langle \psi_0 | e^{-\hat{D}} \hat{X}_1 \hat{X}_2 e^{-\hat{D}} | \psi_0 \rangle = \left( \sum_{g} P^{XX}_{\downarrow\downarrow}(g) \right) \left( \sum_{g} P^{\uparrow\uparrow}_{\downarrow\downarrow}(g) \right).$$

(52)

Here, we utilize the equivalence between fermion spins $\uparrow$ and $\downarrow$. Despite the simple quantum circuits, we notice the sizable discrepancies between the results computed directly from the real quantum device and the analytical results. The discrepancies are more noticeable for $\langle \psi_0 | e^{-\hat{D}} \hat{X}_1 \hat{X}_2 e^{-\hat{D}} | \psi_0 \rangle$, as shown in Fig. 6(c), since the evaluation of $P^{XX}(g)$ involves more CNOT gates than the others (see Fig. 5).

To mitigate the systematic errors, we apply a so-called phase-and-scale (PaS) correction technique developed in the study of spin dynamics [88, 89]. Since the ideal value of $P^{\uparrow\uparrow}_{\downarrow\downarrow}(g)$ at $g = 0$ is known to be one for all $\sigma$, in the PaS correction method, the inverse of the raw data of $P^{\uparrow\uparrow}_{\downarrow\downarrow}(0)$ is multiplied to the raw data of $P^{\uparrow\uparrow}_{\downarrow\downarrow}(g)$ to mitigate the systematic errors. The same strategy is applied to $P^{XX}_{\downarrow\downarrow}(g)$ because $|\psi_0\rangle$ is chosen as the ground state of $\hat{K}$, i.e., a spin singlet state. On the other hand, for the error mitigation in $P^{XX}_{\downarrow\downarrow}(g)$, we use the raw data at a sufficiently large $g$, i.e., $g = 10$, so as to reproduce the value in the strong coupling limit, where the rotation angle $\alpha$ is simply $\frac{\pi}{2}$. This simple technique is found to successfully mitigate the most of the systematic errors, as shown in Fig. 6.

Finally, the total energy $E$ as well as the kinetic energy $\langle \hat{K} \rangle$ and the potential energy $U(\hat{D})$ calculated from these error-mitigated values is shown in Fig. 7. We find that these results are in good agreement with the analytical results within the error bars. We note that the PaS correction technique can in principle be applied for larger systems because the exact values of $\langle \hat{K} \rangle$ with $g = 0$ in the noninteracting limit and $\langle \hat{D} \rangle$ with $g \gg 1$ in the atomic limit can be evaluated efficiently with classical computers or even analytically.
Based on the discrete Hubbard-Stratonovich transformation of the Gutzwiller factor \( e^{-gD} \), we have proposed a scheme to implement the Gutzwiller wave function on a quantum computer and demonstrated it using numerical simulations and a real quantum device. The crucial point is that the nonunitary Gutzwiller factor \( e^{-gD} \) is expressed as a linear combination of unitary operators by introducing the auxiliary fields of the discrete Hubbard-Stratonovich transformation. The sum over the auxiliary fields generates an exponentially large number of terms with respect to the system size \( N_{\text{site}} \), which is here treated by two complementary approaches, one employing a quantum circuit of the linear combination of unitaries to probabilistically prepare the Gutzwiller wave function on a quantum computer and the other using the importance sampling to stochastically evaluate the expectation values for the Gutzwiller wave function.

The first approach performs the sum over all the auxiliary fields by measuring the state of the \( N_{\text{site}} \) ancillary qubits. Although the success probability decreases exponentially in \( N_{\text{site}} \), an advantage of this approach is that the Gutzwiller wave function \( \psi_g \) itself can be prepared on a quantum computer. In this sense, this approach is similar to that reported in Ref. [53]. Indeed, using Eqs. (5) and (7), one can show that the success probability \( p_{\text{success}} \) is exactly the same as that in Ref. [53]. Interestingly, however, the circuit structure is different from that in Ref. [53], as summarized in Table I. While \( N_{\text{site}} \) controlled-controlled-\( \text{R}_Y \) (CCR\( _Y \)) gates are required for preparing the Gutzwiller wave function in the previous study [53], assuming the Jordan-Wigner transformation, here \( 2N_{\text{site}} \) CR\( _Z \) gates are used for the same purpose. In terms of the number of CNOT gates, the implementation of a CR\( _Z \) gate is simpler than that of a CCR\( _Y \) gate because a C\( _R \) gate can be decomposed into 2 CNOT gates and 2 R\( _Z \) gates, while a CCR\( _Y \) gate can be decomposed into 2 Toffoli gates and 2 R\( _Y \) gates [90]. The CNOT gate

V. CONCLUSION AND DISCUSSION

![Quantum circuits for the Hadamard test](image)

FIG. 5. Quantum circuits for the Hadamard test to evaluate the expectation values of (a) \( P_{\psi_0}^\text{qasm}(g) = \langle \psi_0 | \hat{u}_{s_{1,1}} \hat{u}_{s_{1,2}} | \psi_0 \rangle \), (b) \( P_{\psi_0}^\text{qasm}(g) = \langle \psi_0 | \hat{u}_{s_{1,1}} \hat{u}_{s_{1,2}} \hat{X}_{s_{1,1}} \hat{X}_{s_{1,2}} | \psi_0 \rangle \). The real and imaginary part of each expectation value are estimated as \( P_0 - P_1 \) for \( b = 0 \) and 1, respectively. Here, \( P_0 \) is the probability of measuring \( |0\rangle \) at the ancillary qubit and \( P_1 = 1 - P_0 \). The SWAP gate is denoted by a line connecting two crosses. \( S^\dagger \) denotes the single-qubit phase shift gate acting as \( S^\dagger |0\rangle \_0 = |0\rangle \_0 \) and \( S^\dagger |1\rangle \_0 = -i|1\rangle \_0 \).

![Results of expectation values](image)

FIG. 6. Results of (a) \( \langle \psi_0 | e^{-gD} \hat{D} | \psi_0 \rangle \), (b) \( \langle \psi_0 | e^{-gD} \hat{Z}_{s_{1,1}} \hat{Z}_{s_{1,2}} e^{-gD} | \psi_0 \rangle \), and (c) \( \langle \psi_0 | e^{-gD} \hat{X}_{s_{1,1}} \hat{X}_{s_{1,2}} e^{-gD} | \psi_0 \rangle \) as a function of the Gutzwiller parameter \( g \). The results evaluated from the raw data obtained from the IBM Q Manila device are denoted by diamonds, and those after the error mitigation by the PaS correction technique are shown by squares. For comparison, the results calculated on the classical simulator (qasm_simulator) using the same quantum circuits are also plotted by circles, which agree with the analytical results shown by solid lines.
counts for decomposing 2 Cr gates is thus 4, whereas that for decomposing a single CCRy gate is 12 because a Toffoli gate requires 6 CNOT gates [91]. Therefore, in terms of the CNOT gate counts, the present scheme is beneficial for preparing the Gutzwiller wave function on a quantum computer.

We should emphasize that this simplification of the quantum circuit is made possible because our quantum circuit is inspired by the Hubbard-Stratonovich transformation. The Hubbard-Stratonovich transformation allows us to disentangle the two-body operator \( e^{-i\hat{H}_g - \frac{1}{2} \hat{\eta}_0 - \frac{1}{2} \hat{\eta}_1} \) into a linear combination of one-body operators \( e^{i\alpha (\hat{\eta}_0 + \hat{\eta}_1)^1} + e^{-i\alpha (\hat{\eta}_0 + \hat{\eta}_1)^{-1}} \), each of which is then represented simply as a direct product of single-qubit rotations \( R_{Zi} \otimes R_{Zi} \) under the Jordan-Wigner transformation.

Note, however, that the quantum circuit for taking the linear combination of the one-body operators \( \frac{1}{2} (e^{i\alpha (\hat{\eta}_0 + \hat{\eta}_1)^1} + e^{-i\alpha (\hat{\eta}_0 + \hat{\eta}_1)^{-1}}) \) shown in Fig. 1 can also be expressed with controlled-controlled-unitary gates, as shown in Fig. 8. In Fig. 8, \( \mathbf{0} \) is the \( 2 \times 2 \) null matrix, \( \mathbf{I} \) is the \( 2 \times 2 \) identity matrix, and the Hadamard, Z-rotation, and X-rotation matrices are given by

\[
H = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}, \tag{53}
\]

\[
R_z(\alpha) = \begin{bmatrix} e^{-i\alpha/2} & 0 \\ 0 & e^{i\alpha/2} \end{bmatrix}, \tag{54}
\]

and

\[
R_x(\alpha) = \begin{bmatrix} \cos \frac{\alpha}{2} & -i \sin \frac{\alpha}{2} \\ i \sin \frac{\alpha}{2} & \cos \frac{\alpha}{2} \end{bmatrix}, \tag{55}
\]

respectively. The resulting quantum circuit using the controlled-controlled-\( R_x \) gates has an intuitive interpretation similar to Ref. [53]: Let us expand \( \ket{\psi_0} \) by the computational-basis states \( \ket{b} \) as \( \ket{\psi_0} = \sum_b b \ket{b} \ket{\psi_0} \), where \( b \) denotes a bit string of length \( 2N_{\text{site}} \). The operator \( \frac{1}{2} (e^{i\alpha (\hat{\eta}_0 + \hat{\eta}_1)^1} + e^{-i\alpha (\hat{\eta}_0 + \hat{\eta}_1)^{-1}}) \) acts on \( \ket{\psi_0} \) and multiplies a factor \( \cos \alpha = e^{-\alpha/2} \) (corresponding to the diagonal element of \( R_x(\pm 2\alpha) \)) to basis states \( \ket{b} \) if they are in either doubly occupied configuration \( \ket{1}_i \ket{1}_i \) or empty configuration \( \ket{0}_i 
\]

![FIG. 7. The expectation values of (a) the total energy \( E \), (b) the kinetic energy \( \langle \hat{K} \rangle \), and (c) the potential energy \( U(\hat{D}) \) as a function of the Gutzwiller parameter \( g \) for the two-site \( (N_{\text{site}} = 2) \) Fermi-Hubbard model under open-boundary conditions at half filling with \( U/J = 1, 2, 3, 4 \) (top to bottom). The results are obtained from the error-approximated values shown in Fig. 6. For comparison, the exact analytical results are also plotted by solid lines.](image-url)

Appendix A: Discrete Hubbard-Stratonovich transformations

In this Appendix, we provide a general framework for obtaining Hubbard-Stratonovich transformations that transform $e^{-\hat{J}/2\hbar}$ as a linear combination of unitary operators, both for $J < 0$ and $J > 0$. Since $(\hat{\eta}_{\alpha} - \frac{1}{2})(\hat{\eta}_{\alpha'} - \frac{1}{2}) = \frac{1}{4} \hat{Z}_{\alpha} \hat{Z}_{\alpha'}$, this implies that any exponentiated density-density interactions can be decomposed into a linear combination of unitary operators.
1. \(\exp(-J\hat{Z}_j\hat{Z}_i)\) with \(J < 0\)

We consider the case of \(J = -|J| < 0\). We begin with the
matrix representation

\[
e^{-i\hat{J}_i\hat{J}_j} = \begin{bmatrix}
e^{-j} & 0 & 0 & 0 \\
0 & e^{j} & 0 & 0 \\
0 & 0 & e^{j'} & 0 \\
0 & 0 & 0 & e^{-j}
\end{bmatrix}, \quad (A1)
\]

where \(e^{-j} > 1\) and \(e^{j'} < 1\) because \(J < 0\). Next, according to Ref. [105], typical two-qubit two-level unitaries have the matrix representations

\[
\exp\left[-i\frac{\alpha}{2} (\hat{X}_j\hat{X}_j + \hat{Y}_j\hat{Y}_j)\right] = \begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & \cos \alpha & -i \sin \alpha & 0 \\
0 & -i \sin \alpha & \cos \alpha & 0 \\
0 & 0 & 0 & 1
\end{bmatrix}, \quad (A2)
\]

\[
\exp\left[-i\frac{\alpha}{2} (\hat{X}_j\hat{X}_j - \hat{Y}_j\hat{Y}_j)\right] = \begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & \cos \alpha & \sin \alpha & 0 \\
0 & -\sin \alpha & \cos \alpha & 0 \\
0 & 0 & 0 & 1
\end{bmatrix}, \quad (A3)
\]

\[
\exp\left[-i\frac{\alpha}{2} (\hat{Z}_j - \hat{Z}_i)\right] = \begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & e^{ia} & 0 & 0 \\
0 & 0 & e^{-ia} & 0 \\
0 & 0 & 0 & 1
\end{bmatrix}, \quad (A4)
\]

where \(\alpha\) is real. Since \(\sin \alpha \) (\(\cos \alpha\)) is an odd (even) function of \(\alpha\), linear combinations of these two-qubit two-level unitaries with opposite rotation angles result in a diagonal matrix, i.e.,

\[
\sum_{s=1}^{2} \exp\left[-i\frac{\alpha}{2} (\hat{X}_j\hat{X}_j + \hat{Y}_j\hat{Y}_j)\right] = \sum_{s=1}^{2} \exp\left[-i\frac{\alpha}{2} (\hat{X}_j\hat{X}_j - \hat{Y}_j\hat{Y}_j)\right] = \sum_{s=1}^{2} \exp\left[-i\frac{\alpha}{2} (\hat{Z}_j - \hat{Z}_i)\right] = \begin{bmatrix}
2 & 0 & 0 & 0 \\
0 & 2 \cos \alpha & 0 & 0 \\
0 & 0 & 2 \cos \alpha & 0 \\
0 & 0 & 0 & 2
\end{bmatrix}. \quad (A5)
\]

Therefore, comparing Eqs. (A1) and (A5), we find the discrete Hubbard-Stratonovich transformations

\[
e^{-J\hat{Z}_j\hat{Z}_i} = \gamma \sum_{s=1}^{2} \exp\left[-i\frac{\alpha}{2} (\hat{X}_j\hat{X}_j + \hat{Y}_j\hat{Y}_j)\right] \quad (A6)
\]

\[
= \gamma \sum_{s=1}^{2} \exp\left[-i\frac{\alpha}{2} (\hat{X}_j\hat{X}_j - \hat{Y}_j\hat{Y}_j)\right] \quad (A7)
\]

\[
= \gamma \sum_{s=1}^{2} \exp\left[-i\frac{\alpha}{2} (\hat{Z}_i - \hat{Z}_j)\right] \quad (A8)
\]

with \(\gamma = e^{-j/2}\) and \(\alpha = \arccos (e^{j/2})\).

2. \(\exp(-J\hat{Z}_j\hat{Z}_i)\) with \(J > 0\)

Next, we consider the case of \(J > 0\), for which \(e^{-j} < 1\) and \(e^{j'} > 1\) in Eq. (A1). According to Ref. [105], typical two-qubit

two-level unitaries have the matrix representations

\[
\exp\left[-i\frac{\alpha}{2} (\hat{X}_j\hat{X}_j - \hat{Y}_j\hat{Y}_j)\right] = \begin{bmatrix}
\cos \alpha & 0 & 0 & -i \sin \alpha \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
-i \sin \alpha & 0 & 0 & \cos \alpha
\end{bmatrix}, \quad (A9)
\]

\[
\exp\left[-i\frac{\alpha}{2} (\hat{X}_j\hat{Y}_j + \hat{Y}_j\hat{X}_j)\right] = \begin{bmatrix}
\cos \alpha & 0 & 0 & -\sin \alpha \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
\sin \alpha & 0 & 0 & \cos \alpha
\end{bmatrix}, \quad (A10)
\]

\[
\exp\left[-i\frac{\alpha}{2} (\hat{Z}_j + \hat{Z}_i)\right] = \begin{bmatrix}
e^{i\alpha} & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & e^{-\alpha}
\end{bmatrix}. \quad (A11)
\]

where \(\alpha\) is real. Since \(\sin \alpha \) (\(\cos \alpha\)) is an odd (even) function of \(\alpha\), linear combinations of these two-qubit two-level unitaries with opposite rotation angles result in a diagonal matrix, i.e.,

\[
\sum_{s=1}^{2} \exp\left[-i\frac{\alpha}{2} (\hat{X}_j\hat{X}_j - \hat{Y}_j\hat{Y}_j)\right] = \sum_{s=1}^{2} \exp\left[-i\frac{\alpha}{2} (\hat{X}_j\hat{X}_j + \hat{Y}_j\hat{Y}_j)\right] = \sum_{s=1}^{2} \exp\left[-i\frac{\alpha}{2} (\hat{Z}_j + \hat{Z}_i)\right] = \begin{bmatrix}
2 \cos \alpha & 0 & 0 & 0 \\
0 & 2 \cos \alpha & 0 & 0 \\
0 & 0 & 2 \cos \alpha & 0 \\
0 & 0 & 0 & 2 \cos \alpha
\end{bmatrix}. \quad (A12)
\]

Therefore, comparing Eqs. (A1) and (A12), we find the discrete Hubbard-Stratonovich transformations

\[
e^{-J\hat{Z}_j\hat{Z}_i} = \gamma \sum_{s=1}^{2} \exp\left[-i\frac{\alpha}{2} (\hat{X}_j\hat{X}_j - \hat{Y}_j\hat{Y}_j)\right] \quad (A13)
\]

\[
= \gamma \sum_{s=1}^{2} \exp\left[-i\frac{\alpha}{2} (\hat{X}_j\hat{Y}_j + \hat{Y}_j\hat{X}_j)\right] \quad (A14)
\]

\[
= \gamma \sum_{s=1}^{2} \exp\left[-i\frac{\alpha}{2} (\hat{Z}_j + \hat{Z}_i)\right] \quad (A15)
\]

with \(\gamma = e^{j'/2}\) and \(\alpha = \arccos (e^{j'/2})\).

Equation (A15) corresponds to the discrete Hubbard-Stratonovich transformation in Ref. [59] and is adopted here in this study, while Eqs. (A13) and (A14) are different discrete Hubbard-Stratonovich transformations, which might be useful for other purposes. Finally, we note that Eqs. (A13) and (A14) are similar to the discrete Hubbard-Stratonovich transformation for fermions in anomalous channels discussed in Ref. [106].

Appendix B: Absence of the phase problem

In this Appendix, we prove that the phase problem is absent for our particular case, i.e., \(|\psi_0\rangle\) being the ground state of \(\hat{K}\) on a bipartite lattice composed of sublattices \(A\) and \(B\) at half
filling. For this purpose, we introduce a unitary operator $\hat{U}_{\text{pPH}}$ for the partial particle-hole (pPH) transformation such that

$$\hat{U}_{\text{pPH}} \hat{t}_i \hat{U}_{\text{pPH}}^{-1} = \hat{t}_i^\dagger,$$  \hspace{1cm} (B1)

$$\hat{U}_{\text{pPH}} \hat{e}_i \hat{U}_{\text{pPH}}^{-1} = (-1)^i \hat{e}^\dagger_i,$$  \hspace{1cm} (B2)

where $(-1)^i$ takes the different sign when site $i$ belongs to the different sublattice on the bipartite lattice. We assume that the number of sites is even. Since $\hat{U}_{\text{pPH}} \hat{K} \hat{U}_{\text{pPH}}^{-1} = \hat{K}$ and $\hat{U}_{\text{pPH}} \hat{D} \hat{U}_{\text{pPH}}^{-1} = -\hat{D}$, $\hat{K}$ is invariant but $\hat{H}$ is not invariant under the pPH transformation. Rather, the pPH transformation transforms the repulsive Fermi-Hubbard model to the attractive Fermi-Hubbard model [107]. An explicit form of $\hat{U}_{\text{pPH}}$ can be written as $\hat{U}_{\text{pPH}} = \prod_i \hat{e}_i^\dagger (-1)^i \hat{e}_i^\dagger$ (see for example Refs. [108, 109]).

We also introduce an antiunitary operator $\hat{A}_{\text{TR}}$ for the time-reversal (TR) operation such that

$$\hat{A}_{\text{TR}} \hat{c}_i \hat{A}_{\text{TR}}^{-1} = \hat{c}_i^\dagger,$$  \hspace{1cm} (B3)

$$\hat{A}_{\text{TR}} \hat{e}_i \hat{A}_{\text{TR}}^{-1} = -\hat{e}_i,$$  \hspace{1cm} (B4)

and similarly for $\hat{c}^\dagger_i$. The TR operator $\hat{A}_{\text{TR}}$ can be written as $\hat{A}_{\text{TR}} = \hat{U}_{\text{TR}} \hat{C}$, where $\hat{U}_{\text{TR}}$ is a unitary operator and $\hat{C}$ is the complex-conjugation operator, and hence

$$\hat{A}_{\text{TR}} \hat{z} \hat{A}_{\text{TR}}^{-1} = z^*$$  \hspace{1cm} (B5)

for any complex number $z$. We note that the unitary part $\hat{U}_{\text{TR}}$ of the TR operator can be explicitly written as $\hat{U}_{\text{TR}} = \prod_i \hat{f}_{i,i'} \hat{f}_{i,i'}^\dagger e^{i\phi_{i,i'}}$, where $\hat{f}_{i,i'} = 1 + (\hat{c}_{i'} \hat{c}_{i'}^\dagger + \text{H.c.}) - \hat{c}_i \hat{c}_i^\dagger - \hat{c}^\dagger_i \hat{c}^\dagger_i$, is the fermionic SWAP operator [80, 81, 105, 110–113] and $e^{i\phi_{i,i'}} = 1 + (e^{i\phi} - 1) \hat{n}_{i,i'} = 1 - 2 \hat{n}_{i,i'}$ accounts for the gauge transformation [109] for the spin-down fermions in Eq. (B4). From the properties of the fermionic SWAP operator [105] it can be confirmed that $\hat{A}_{\text{TR}}^\dagger = \prod_i (-1)^{\hat{n}_{i,i'+\hat{n}_{i',i}}}$ and $\hat{A}_{\text{TR}} \hat{A}_{\text{TR}}^{-1} = \hat{K}$. Since $\hat{A}_{\text{TR}} \hat{K} \hat{A}_{\text{TR}}^{-1} = \hat{K}$ and $\hat{A}_{\text{TR}} \hat{D} \hat{A}_{\text{TR}}^{-1} = \hat{D}$, $\hat{K}$ and $\hat{D}$ are invariant under the TR operation.

For the later convenience, we also introduce another antiunitary operator $\hat{\Theta}$ as $\hat{\Theta} = \hat{U}_{\text{pPH}} \hat{A}_{\text{TR}}$. It follows from $\hat{\Theta} \hat{K} \hat{\Theta}^{-1} = \hat{K}$ that, if $|\psi_0\rangle$ is an eigenstate of $\hat{K}$, then $|\psi_0\rangle \equiv \hat{\Theta} |\psi_0\rangle$ is also an eigenstate of $\hat{K}$ with the same eigenvalue. It should be reminded that, if $\hat{A}$ is an antiunitary operator, $|\psi\rangle$ and $|\phi\rangle$ are some states, and $|\tilde{\psi}\rangle \equiv \hat{A} |\psi\rangle$ and $|\tilde{\phi}\rangle \equiv \hat{A} |\phi\rangle$ are the antiunitary-operated states associated with $|\psi\rangle$ and $|\phi\rangle$, respectively, then a matrix element $\langle \tilde{\psi} | \tilde{\phi} \rangle$ of a linear operator $\tilde{\hat{X}}$ can be written in terms of $\langle \phi | \hat{X} | \psi \rangle$ [114, 115]

$$\langle \tilde{\phi} | \tilde{\hat{X}} | \tilde{\psi} \rangle = \langle \phi | \hat{X}^\dagger \hat{A}^\dagger \hat{A}^{-1} | \psi \rangle.$$  \hspace{1cm} (B6)

Now we consider how the operator $\hat{u}_{s,r} \equiv \prod_i \hat{u}_{s,i,r}$ for a given set of auxiliary fields $s = \{s_i\}$ is transformed by $\hat{U}_{\text{pPH}}, \hat{\Theta}_{\text{TR}}, \hat{A}_{\text{TR}}$, and $\hat{A}_{\text{TR}}^{-1}$. From Eqs. (B1) and (B2), it follows that

$$\hat{U}_{\text{pPH}} (\hat{u}_{s,1} \otimes \hat{u}_{s,1}) \hat{U}_{\text{pPH}}^{-1} = \hat{u}^*_{s,1} \otimes \hat{u}^*_{s,1}. $$  \hspace{1cm} (B7)

From Eqs. (B3), (B4) and (B5), it follows that

$$\hat{A}_{\text{TR}} (\hat{u}_{s,1} \otimes \hat{u}_{s,1}) \hat{A}_{\text{TR}}^{-1} = \hat{u}^*_{s,1} \otimes \hat{u}^*_{s,1}. $$  \hspace{1cm} (B8)

From Eqs. (B7) and (B8), it follows that

$$\hat{\Theta} (\hat{u}_{s,1} \otimes \hat{u}_{s,1}) \hat{\Theta}^{-1} = \hat{u}^*_{s,1} \otimes \hat{u}^*_{s,1}. $$  \hspace{1cm} (B9)

We also note that $\hat{u}^*_{s,r} = \hat{u}^*_{s,r'}$ because $[\hat{u}_{s,r}, \hat{u}^*_{s,r'}] = 0$. Next we consider the matrix element

$$W \equiv \langle \psi_0 | \hat{u}_{s,1} \otimes \hat{u}_{s,1} | \psi_0 \rangle,$$  \hspace{1cm} (B10)

which corresponds to the numerator of $P_s$ in Eq. (30). Here, we assume that $|\psi_0\rangle$ is the unique ground state of $\hat{K}$, implying that $|\psi_0\rangle \equiv \hat{\Theta} |\psi_0\rangle$ differs from $|\psi_0\rangle$ only by a phase factor, $|\psi_0\rangle \equiv e^{i\theta} |\psi_0\rangle$. Note also that $|\psi_0\rangle$ is a spin-nerable state. Then, by noticing that $\hat{\Theta}$ is an antiunitary operator, $W$ can be written as

$$W = \langle \psi_0 \rangle \langle \hat{u}_{s,1} \hat{u}_{s,1}^\dagger \hat{\Theta} \hat{\Theta}^{-1} | \psi_0 \rangle = \langle \hat{\Theta} | \hat{u}_{s,1} \hat{u}_{s,1}^\dagger | \hat{\Theta} \langle \psi_0 \rangle \rangle = \langle \psi_0 \rangle \langle \hat{u}_{s,1} \hat{u}_{s,1}^\dagger \rangle.$$  \hspace{1cm} (B11)

Here, we have used Eq. (B6) in the first equality and Eq. (B9) in the second equality. Since $\hat{A}_{\text{TR}} \hat{K}_{s} \hat{A}_{\text{TR}}^{-1} = \hat{K}_{s}$ and $\hat{A}_{\text{TR}} \hat{D} \hat{A}_{\text{TR}}^{-1} = \hat{D}$, $\hat{K}_s$ and $\hat{D}$ are invariant under the TR operation. Then, by noticing that $\hat{A}_{\text{TR}}$ is antiunitary, $W_1$ in Eq. (B11) can be written as

$$W_1 = \langle \psi_0 | \hat{A}_{\text{TR}} \hat{u}_{s,1} \hat{A}_{\text{TR}}^{-1} | \psi_0 \rangle = \langle \psi_0 | \hat{u}_{s,1} \langle \psi_0 \rangle \rangle = W_1^*.$$  \hspace{1cm} (B12)

Therefore, $W = |W_1|^2 > 0$, proving that the phase problem is absent in this case. This is essentially the same argument used to prove the absence of the negative sign problem for the Fermi-Hubbard model in the auxiliary-field quantum Monte-Carlo method [116–118].
