Generating Series of the Poincaré Polynomials of Quasihomogeneous Hilbert Schemes

A. Buryak and B.L. Feigin

Abstract In this paper we prove that the generating series of the Poincaré polynomials of quasihomogeneous Hilbert schemes of points in the plane has a beautiful decomposition into an infinite product. We also compute the generating series of the numbers of quasihomogeneous components in a moduli space of sheaves on the projective plane. The answer is given in terms of characters of the affine Lie algebra \( \widehat{sl}_m \).

1 Introduction

The Hilbert scheme \((\mathbb{C}^2)^[n]\) of \(n\) points in the plane \(\mathbb{C}^2\) parametrizes ideals \(I \subset \mathbb{C}[x, y]\) of colength \(n\): \(\dim_{\mathbb{C}} \mathbb{C}[x, y]/I = n\). There is an open dense subset of \((\mathbb{C}^2)^[n]\), that parametrizes the ideals, associated with configurations of \(n\) distinct points. The Hilbert scheme of \(n\) points in the plane is a nonsingular, irreducible,
quasiprojective algebraic variety of dimension 2n with a rich and much studied geometry, see [9, 22] for an introduction.

The cohomology groups of \((\mathbb{C}^2)^n\) were computed in [6] and we refer the reader to the papers [5, 15–17, 24] for the description of the ring structure in the cohomology \(H^*(\mathbb{C}^2)^n\).

There is a \((\mathbb{C}^*)^2\)-action on \((\mathbb{C}^2)^n\) that plays a central role in this subject. The algebraic torus \((\mathbb{C}^*)^2\) acts on \(\mathbb{C}^2\) by scaling the coordinates, \((t_1, t_2) \cdot (x, y) = (t_1 x, t_2 y)\). This action lifts to the \((\mathbb{C}^*)^2\)-action on the Hilbert scheme \((\mathbb{C}^2)^n\).

Let \(T_{\alpha, \beta} = \{(t^\alpha, t^\beta) \in (\mathbb{C}^*)^2 | t \in \mathbb{C}^*\}\), where \(\alpha, \beta \geq 1\) and \(gcd(\alpha, \beta) = 1\), be a one dimensional subtorus of \((\mathbb{C}^*)^2\). The variety \(((\mathbb{C}^2)^n)_{T_{\alpha, \beta}}\) parametrizes quasi-homogeneous ideals of colength \(n\) in the ring \(\mathbb{C}[x, y]\). Irreducible components of \(((\mathbb{C}^2)^n)_{T_{\alpha, \beta}}\) were described in [7]. Poincaré polynomials of irreducible components in the case \(\alpha = 1\) were computed in [3]. For \(\alpha = \beta = 1\) it was done in [12].

For a manifold \(X\) let \(H_*(X)\) denote the homology group of \(X\) with rational coefficients. Let 
\[ P_q(X) = \sum_{i \geq 0} \dim H_i(X) q^2. \]

The main result of this paper is the following theorem (it was conjectured in [3]):

**Theorem 1**

\[
\sum_{n \geq 0} P_q(((\mathbb{C}^2)^n)_{T_{\alpha, \beta}}) t^n = \prod_{i \geq 1} \frac{1}{1 - t_i} \prod_{i \geq 1} \frac{1}{1 - q t((\alpha + \beta) i)}. \tag{1}
\]

There is a standard method for constructing a cell decomposition of the Hilbert scheme \(((\mathbb{C}^2)^n)_{T_{\alpha, \beta}}\) using the Bialynicki-Birula theorem. In this way the Poincaré polynomial of this Hilbert scheme can be written as a generating function for a certain statistic on Young diagrams of size \(n\). However, it happens that this combinatorial approach doesn’t help in a proof of Theorem 1. In fact, we get very nontrivial combinatorial identities as a corollary of this theorem, see Sect. 1.1.

We can describe the main geometric idea in the proof of Theorem 1 in the following way. The irreducible components of \(((\mathbb{C}^2)^n)_{T_{\alpha, \beta}}\) can be realized as fixed point sets of a \(\mathbb{C}^*\)-action on cyclic quiver varieties. Theorem 4 tells us that the Betti numbers of the fixed point set are equal to the shifted Betti numbers of the quiver variety. Then known results about cohomology of quiver varieties can be used for a proof of Theorem 1.

In principle, Theorem 4 has an independent interest. However, there is another application of this theorem. In [4] we studied the generating series of the numbers of quasihomogeneous components in a moduli space of sheaves on the projective plane. Combinatorially we managed to compute it only in the simplest case. Now using Theorem 4 we can give an answer in a general case, this is Theorem 5. We show that it proves our conjecture from [4].
1.1 Combinatorial Identities

Here we formulate two combinatorial identities that follow from Theorem 1. We denote by $\mathcal{Y}$ the set of all Young diagrams. For a Young diagram $Y$ let

$$r_l(Y) = |\{(i, j) \in Y | j = l\}|,$$

$$c_l(Y) = |\{(i, j) \in Y | i = l\}|.$$

For a point $s = (i, j) \in \mathbb{Z}_{\geq 0}^2$ let

$$l_Y(s) = r_j(Y) - i - 1,$$

$$a_Y(s) = c_i(Y) - j - 1,$$

see Fig. 1. Note that $l_Y(s)$ and $a_Y(s)$ are negative, if $s \notin Y$.

The number of boxes in a Young diagram $Y$ is denoted by $|Y|$. Theorem 2

Let $\alpha$ and $\beta$ be two arbitrary positive coprime integers. Then we have

$$\sum_{Y \in \mathcal{Y}} q^{\#\{s \in Y | \alpha l_Y(s) = \beta (a_Y(s)+1)\}} t^{|Y|} = \prod_{i \geq 1} \frac{1}{1-t^i} \prod_{i \geq 1} \frac{1}{1-q t^{(\alpha+\beta)i}}.$$

In the case $\alpha = \beta = 1$ another identity can be derived from Theorem 1. The $q$-binomial coefficients are defined by

$$\left[\begin{array}{c} M \\ N \end{array}\right]_q = \frac{\prod_{i=1}^M (1-q^i)}{\prod_{i=1}^N (1-q^i) \prod_{i=1}^{M-N} (1-q^i)}.$$

By $\mathcal{P}$ we denote the set of all partitions. For a partition $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_r), \lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_r$, let $|\lambda| = \sum_{i=1}^r \lambda_i$.

Theorem 3

$$\sum_{\lambda \in \mathcal{P}} \prod_{i \geq 1} \left[\begin{array}{c} \lambda_i - \lambda_{i+2} + 1 \\ \lambda_{i+1} - \lambda_{i+2} \end{array}\right]_q t^{\frac{\lambda_i(\lambda_i-1)}{2} + |\lambda|} = \prod_{i \geq 1} \frac{1}{(1-t^{2i-1})(1-q t^{2i})}.$$ 

Fig. 1  Arms and legs in a Young diagram

$\begin{array}{|c|c|}
\hline
\downarrow & \downarrow \\

\end{array}$

$l_Y(s) = \text{number of } \blacklozenge$

$a_Y(s) = \text{number of } \blacklozenge$

$Y$
Here for a partition $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_r)$, $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_r$, we adopt the convention $\lambda_{>r} = 0$.

1.2 Cyclic Quiver Varieties

Quiver varieties were introduced by H. Nakajima in [20]. Here we review the construction in the particular case of cyclic quiver varieties. We follow the approach from [21].

Let $m \geq 2$. We fix vector spaces $V_0, V_1, \ldots, V_{m-1}$ and $W_0, W_1, \ldots, W_{m-1}$ and we denote by $v = (\dim V_0, \ldots, \dim V_{m-1}), w = (\dim W_0, \ldots, \dim W_{m-1}) \in \mathbb{Z}_{\geq 0}^m$ the dimension vectors. We adopt the convention $V_m = V_0$. Let

$$M(v, w) = \bigoplus_{k=0}^{m-1} \text{Hom}(V_k, V_{k+1}) \oplus \bigoplus_{k=0}^{m-1} \text{Hom}(V_k, V_{k-1}) \oplus \bigoplus_{k=0}^{m-1} \text{Hom}(W_k, V_k) \oplus \bigoplus_{k=0}^{m-1} \text{Hom}(V_k, W_k).$$

The group $G_v = \prod_{k=0}^{m-1} \text{GL}(V_k)$ acts on $M(v, w)$ by

$$g \cdot (B_1, B_2, i, j) \mapsto (g B_1 g^{-1}, g B_2 g^{-1}, g i, g j^{-1}).$$

The map $\mu : M(v, w) \to \bigoplus_{k=0}^{m-1} \text{Hom}(V_k, V_k)$ is defined as follows

$$\mu(B_1, B_2, i, j) = [B_1, B_2] + i j.$$

Let

$$\mu^{-1}(0)^s = \left\{ (B, i, j) \in \mu^{-1}(0) \middle| \begin{array}{l}
\text{if a collection of subspaces } S_k \subset V_k \\
\text{is } B\text{-invariant and contains } \text{Im}(i), \text{then } S_k = V_k
\end{array} \right\}.$$

The action of $G_v$ on $\mu^{-1}(0)^s$ is free. The quiver variety $\mathcal{M}(v, w)$ is defined as the quotient

$$\mathcal{M}(v, w) = \mu^{-1}(0)^s / G_v,$$

see Fig. 2.

The variety $\mathcal{M}(v, w)$ is irreducible (see e.g. [21]).

We define the $(\mathbb{C}^*)^2 \times (\mathbb{C}^*)^m$-action on $\mathcal{M}(v, w)$ as follows:

$$(t_1, t_2, e_k) \cdot (B_1, B_2, i_k, j_k) = (t_1 B_1, t_2 B_2, e_k^{-1} i_k, t_1 t_2 e_k j_k).$$
In this section we formulate Theorem 4 that is a key step in the proofs of Theorems 1 and 5.

Let $\alpha$ and $\beta$ be any two positive coprime integers, such that $\alpha + \beta = m$. Define the integers $\lambda_0, \lambda_1, \ldots, \lambda_{m-1} \in [-m, 0]$ by the formula $\lambda_k \equiv -ak \mod m$. We define the one-dimensional subtorus $\tilde{T}_{\alpha, \beta} \subset (\mathbb{C}^*)^2 \times (\mathbb{C}^*)^m$ by

$$\tilde{T}_{\alpha, \beta} = \{ (t^\alpha, t^\beta, t^{\lambda_0}, t^{\lambda_1}, \ldots, t^{\lambda_{m-1}}) \in (\mathbb{C}^*)^2 \times (\mathbb{C}^*)^m | t \in \mathbb{C}^* \}.$$

For a manifold $X$ we denote by $H^*_{BM}(X)$ the homology group of possibly infinite singular chains with locally finite support (the Borel-Moore homology) with rational coefficients. Let $P^*_{BM}(X) = \sum_{i \geq 0} \dim H^i_{BM}(X)q^{\frac{i}{2}}$.

**Theorem 4** The fixed point set $\mathcal{M}(v, w)^{\tilde{T}_{\alpha, \beta}}$ is compact and

$$P^*_{BM}(\mathcal{M}(v, w)^{\tilde{T}_{\alpha, \beta}}) = q^{\frac{1}{2}\dim \mathcal{M}(v, w)} P_q(\mathcal{M}(v, w)^{\tilde{T}_{\alpha, \beta}}).$$
1.4 Quasihomogeneous Components in the Moduli Space of Sheaves

Here we formulate our result that relates the numbers of quasihomogeneous components in a moduli space of sheaves with characters of the affine Lie algebra $\widehat{sl}_m$.

The moduli space $\mathcal{M}(r, n)$ is defined as follows (see e.g. [22]):

$$\mathcal{M}(r, n) = \{(B_1, B_2, i, j) \mid (1) \ [B_1, B_2] + ij = 0 \text{ (1) } \text{ (stability)} \text{ There is no subspace } S \subseteq \mathbb{C}^n \text{ such that } B_\alpha(S) \subseteq S \text{ (} \alpha = 1, 2 \text{)} \text{ and } \text{Im}(i) \subseteq S \} / GL_n(\mathbb{C}),$$

where $B_1, B_2 \in \text{End}(\mathbb{C}^n), i \in \text{Hom}(\mathbb{C}^r, \mathbb{C}^n)$ and $j \in \text{Hom}(\mathbb{C}^n, \mathbb{C}^r)$ with the action of $GL_n(\mathbb{C})$ given by

$$g \cdot (B_1, B_2, i, j) = (g B_1 g^{-1}, g B_2 g^{-1}, g i, g j^{-1}).$$

for $g \in GL_n(\mathbb{C})$.

The variety $\mathcal{M}(r, n)$ has another description as the moduli space of framed torsion free sheaves on the projective plane, but for our purposes the given definition is better. We refer the reader to [22] for details. The variety $\mathcal{M}(1, n)$ is isomorphic to $(\mathbb{C}^*)^n$ (see e.g. [22]).

Define the $(\mathbb{C}^*)^2 \times (\mathbb{C}^*)^r$-action on $\mathcal{M}(r, n)$ by

$$(t_1, t_2, e) \cdot [(B_1, B_2, i, j)] = [(t_1 B_1, t_2 B_2, ie^{-1}, t_1 t_2 e j)].$$

Consider two positive coprime integers $\alpha$ and $\beta$ and a vector

$$\omega = (\omega_1, \omega_2, \ldots, \omega_r) \in \mathbb{Z}^r$$

such that $0 \leq \omega_i < \alpha + \beta$. Let $T^\omega_{\alpha, \beta}$ be the one-dimensional subtorus of $(\mathbb{C}^*)^2 \times (\mathbb{C}^*)^r$ defined by

$$T^\omega_{\alpha, \beta} = \{(t^\alpha, t^\beta, t^{\omega_1}, t^{\omega_2}, \ldots, t^{\omega_r}) \in (\mathbb{C}^*)^2 \times (\mathbb{C}^*)^r \mid t \in \mathbb{C}^* \}.$$ 

In [4] we studied the numbers of the irreducible components of $\mathcal{M}(r, n)^{T^\omega_{\alpha, \beta}}$ and found an answer in the case $\alpha = \beta = 1$. Now we can solve the general case.

We define the vector $\rho = (\rho_0, \rho_1, \ldots, \rho_{\alpha + \beta - 1}) \in \mathbb{Z}_{\geq 0}^{\alpha + \beta}$ by $\rho_i = \mathbb{Z}[j \mid \omega_j = i]$ and the vector $\mu \in \mathbb{Z}_{\geq 0}^{\alpha + \beta}$ by $\mu_i = \rho - i \alpha \text{mod} \alpha + \beta$.

Let $E_k, F_k, H_k, k = 1, 2, \ldots, \alpha + \beta$, be the standard generators of $\widehat{sl}_{\alpha + \beta}$. Let $\mathcal{V}$ be the irreducible highest weight representation of $\widehat{sl}_{\alpha + \beta}$ with the highest weight $\mu$. Let $x \in \mathcal{V}$ be the highest weight vector. We denote by $\mathcal{V}_p$ the vector subspace of $\mathcal{V}$ generated by vectors $F_{i_1} F_{i_2} \ldots F_{i_p} x$. The character $\chi_\mu(q)$ is defined by

$$\chi_\mu(q) = \sum_{p \geq 0} (\dim \mathcal{V}_p) q^p.$$

We denote by $h_0(X)$ the number of connected components of a manifold $X$. 
Theorem 5
\[
\sum_{n \geq 0} h_0(\mathcal{M}(r, n)^{T_{\alpha, \beta}})q^n = \chi_\mu(q).
\]

In [14] the authors found a combinatorial formula for characters of \(\hat{sl}_m\) in terms of Young diagrams with certain restrictions. In [8] the same combinatorics is used to give a formula for certain characters of the quantum continuous \(gl_\infty\). Comparing these two combinatorial formulas it is easy to see that Conjecture 1.2 from [4] follows from Theorem 5.

Remark 1 There is a small mistake in Conjecture 1.2 from [4]. The vector \(a' = (a'_0, a'_1, \ldots, a'_{\alpha+\beta-1})\) should be defined by \(a'_i = a_i - ai \mod \alpha + \beta\). The rest is correct.

1.5 Organization of the Paper

We prove Theorem 4 in Sect. 2. Then using this result we prove Theorem 1 in Sect. 3. In Sect. 4 we derive the combinatorial identities as a corollary of Theorem 1. Finally, using Theorem 4 we prove Theorem 5 in Sect. 5.

2 Proof of Theorem 4

In this section we prove Theorem 4. The Grothendieck ring of quasiprojective varieties is a useful technical tool and we remind its definition and necessary properties in Sect. 2.1.

2.1 Grothendieck Ring of Quasiprojective Varieties

The Grothendieck ring \(K_0(v_\mathbb{C})\) of complex quasiprojective varieties is the abelian group generated by the classes \([X]\) of all complex quasiprojective varieties \(X\) modulo the relations:

1. if varieties \(X\) and \(Y\) are isomorphic, then \([X] = [Y]\);
2. if \(Y\) is a Zariski closed subvariety of \(X\), then \([X] = [Y] + [X \setminus Y]\).

The multiplication in \(K_0(v_\mathbb{C})\) is defined by the Cartesian product of varieties: \([X_1] \cdot [X_2] = [X_1 \times X_2]\). The class \([\mathbb{A}_\mathbb{C}^1]\) \(\in K_0(v_\mathbb{C})\) of the complex affine line is denoted by \(\mathbb{L}\).

We need the following property of the ring \(K_0(v_\mathbb{C})\). There is a natural homomorphism of rings \(\theta: \mathbb{Z}[z] \to K_0(v_\mathbb{C})\), defined by \(\theta(z) = \mathbb{L}\). This homomorphism is an inclusion (see e.g. [18]).
2.2 Proof of Theorem 4

Let \( r = \sum_{i=0}^{m-1} \theta_i \). For an arbitrary \( v \in \mathbb{Z}^r \) let \( \Gamma_{\alpha,\beta}^v \subset T_{\alpha,\beta}^v \) be the subgroup of roots of 1 of degree \( m \). Let

\[
\theta = (0, \ldots, 0, \lambda_1, \ldots, \lambda_{m-1}, \ldots, \lambda_{m-1}) \in \mathbb{Z}^r.
\]

Lemma 1 1. We have the following decomposition into irreducible components

\[
\mathcal{M}(r, n)^{\Gamma_{\alpha,\beta}^\theta} = \bigcup_{v \in \mathbb{Z}^m} \mathcal{M}(v, w). \tag{2}
\]

2. The \( T_{\alpha,\beta}^\theta \)-action on the left-hand side of (2) corresponds to the \( \widetilde{T}_{\alpha,\beta} \)-action on the right-hand side of (2).

Proof Let \( \Gamma_m \) be the group of roots of unity of degree \( m \). By definition, a point \( [B_1, B_2, i, j] \in \mathcal{M}(r, n) \) is fixed under the action of \( \Gamma_{\alpha,\beta}^\theta \) if and only if there exists a homomorphism \( \lambda: \Gamma_m \to GL_n(\mathbb{C}) \) satisfying the following conditions:

\[
\begin{align*}
\zeta^\alpha B_1 &= \lambda(\xi)^{-1} B_1 \lambda(\xi), \\
\zeta^\beta B_2 &= \lambda(\xi)^{-1} B_2 \lambda(\xi), \\
i \circ \text{diag}(\zeta^{\theta_1}, \zeta^{\theta_2}, \ldots, \zeta^{\theta_r})^{-1} &= \lambda(\xi)^{-1} i, \\
\text{diag}(\zeta^{\theta_1}, \zeta^{\theta_2}, \ldots, \zeta^{\theta_r}) \circ j &= j \lambda(\xi),
\end{align*}
\]

where \( \xi = e^{-\frac{\pi \sqrt{-1}}{m}} \). Suppose that \( [B_1, B_2, i, j] \) is a fixed point. Then we have the weight decomposition of \( \mathbb{C}^n \) with respect to \( \lambda(\xi) \), i.e. \( \mathbb{C}^n = \bigoplus_{k \in \mathbb{Z}/m\mathbb{Z}} V'_k \), where \( V'_k = \{ v \in \mathbb{C}^n | \lambda(\xi) \cdot v = \xi^k v \} \). We also have the weight decomposition of \( \mathbb{C}^r \), i.e. \( \mathbb{C}^r = \bigoplus_{k \in \mathbb{Z}/m\mathbb{Z}} W'_k \), where \( W'_k = \{ v \in \mathbb{C}^r | \text{diag}(\zeta^{\theta_1}, \ldots, \zeta^{\theta_r}) \cdot v = \xi^k v \} \). From conditions (3) it follows that the only components of \( B_1, B_2, i \) and \( j \) that might survive are:

\[
\begin{align*}
B_1: V'_k &\to V'_{k-\alpha}, \\
B_2: V'_k &\to V'_{k-\beta}, \\
i: W'_k &\to V'_k, \\
j: V'_k &\to W'_k.
\end{align*}
\]

Let us denote \( V'_{-\alpha k \mod m} \) by \( V_k \) and \( W'_{-\alpha k \mod m} \) by \( W_k \). Then the operators \( B_1, B_2, i, j \) act as follows: \( B_{1,2}: V_k \to V_{k \pm 1}, i: W_k \to V_k, j: V_k \to W_k \). The first
part of the lemma is proved. The second part of the lemma easily follows from the proof of the first part and from the definition of the $\tilde{T}_{\alpha, \beta}$-action.

In [4] it is proved that the variety $\mathcal{M}(r, n)^T_{\theta\alpha, \beta}$ is compact. Therefore, $\mathcal{M}(v, w)_{\tilde{T}_{\alpha, \beta}}$ is compact.

We denote by $\mathcal{M}(r, n)^T_{\theta\alpha, \beta}$ the irreducible component of $\mathcal{M}(r, n)^T_{\theta\alpha, \beta}$ corresponding to $\mathcal{M}(v, w)$. Let $\mathcal{M}(r, n)^T_{\theta\alpha, \beta}$ be the decomposition into the irreducible components. We define the sets $\mathcal{C}_{v,i}$ by

$$C_{v,i} = \left\{ z \in \mathcal{M}(r, n)^T_{\theta\alpha, \beta} \mid \lim_{t \to 0, t \in T_{\theta\alpha, \beta}} tz \in \mathcal{M}(r, n)^T_{\theta\alpha, \beta} \right\}.$$

**Lemma 2**

1. The sets $\mathcal{C}_{v,i}$ form a decomposition of $\mathcal{M}(r, n)^T_{\theta\alpha, \beta}$ into locally closed subvarieties.
2. The subvariety $\mathcal{C}_{v,i}$ is a locally trivial bundle over $\mathcal{M}(r, n)^T_{\theta\alpha, \beta}$ with an affine space as a fiber.

**Proof** The lemma follows from the results of [1, 2]. The only thing that we need to check is that the limit $\lim_{t \to 0, t \in T_{\theta\alpha, \beta}} tz$ exists for any $z \in \mathcal{M}(r, n)^T_{\theta\alpha, \beta}$.

Consider the variety $\mathcal{M}_0(r, n)$ from [23]. It is defined as the affine algebro-geometric quotient

$$\mathcal{M}_0(r, n) = \{(B_1, B_2, i, j) \mid [B_1, B_2] + ij = 0\} / GL_n(\mathbb{C}).$$

It can be viewed as the set of closed orbits in $\{(B_1, B_2, i, j) \mid [B_1, B_2] + ij = 0\}$. There is a morphism $\pi : \mathcal{M}(r, n) \to \mathcal{M}_0(r, n)$. It maps a point $[(B_1, B_2, i, j)] \in \mathcal{M}(r, n)$ to the unique closed orbit that is contained in the closure of the orbit of $(B_1, B_2, i, j)$ in $\{(B_1, B_2, i, j) \mid [B_1, B_2] + ij = 0\}$. The $(\mathbb{C}^*)^2 \times (\mathbb{C}^*)^r$-action on $\mathcal{M}_0(r, n)$ is defined in the same way as on $\mathcal{M}(r, n)$. The variety $\mathcal{M}_0(r, n)$ is affine and the morphism $\pi$ is projective and equivariant (see e.g. [23]).

By [19], the coordinate ring of $\mathcal{M}_0(r, n)$ is generated by the following two types of functions:

(a) $\text{tr}(B_{a_N} B_{a_{N-1}} \cdots B_{a_1} : \mathbb{C}^n \to \mathbb{C}^n)$, where $a_i = 1$ or 2.

(b) $\chi(j B_{a_N} B_{a_{N-1}} \cdots B_{a_1} i)$, where $a_i = 1$ or 2, and $\chi$ is a linear form on $\text{End}(\mathbb{C}^r)$.

From the inequalities $-m < \theta_k \leq 0$ it follows that both types of functions have positive weights with respect to the $T_{\theta\alpha, \beta}$-action. Therefore, for any point $z \in \mathcal{M}_0(r, n)$ we have $\lim_{t \to 0, t \in T_{\theta\alpha, \beta}} tz = 0$. The morphism $\pi$ is projective, so the limit $\lim_{t \to 0, t \in T_{\theta\alpha, \beta}} tz$ exists for any $z \in \mathcal{M}(r, n)^T_{\theta\alpha, \beta}$. The lemma is proved. □
Denote by $d_{v,i}^+$ the dimension of the fiber of the locally trivial bundle $C_{v,i} \to M^{T_{\alpha,\beta}}_{v,i}$.

**Lemma 3** The dimension $d_{v,k}^+$ doesn’t depend on $k \in I_v$ and is equal to

$$d_{v,k}^+ = \frac{1}{2} \dim \mathcal{M}(v, w).$$

**Proof** The set of fixed points of the $(\mathbb{C}^*)^2 \times (\mathbb{C}^*)^r$-action on $\mathcal{M}(r, n)$ is finite and is parametrized by the set of $r$-tuples $D = (D_1, D_2, \ldots, D_r)$ of Young diagrams $D_i$ such that $\sum_{i=1}^r |D_i| = n$ (see e.g. [23]).

Let $p \in \mathcal{M}(r, n)^{((\mathbb{C}^*)^2 \times (\mathbb{C}^*)^r)}$ be the fixed point corresponding to an $r$-tuple $D$. Let $R((\mathbb{C}^*)^2 \times (\mathbb{C}^*)^r) = \mathbb{Z}[l_{1\pm 1}, l_{2\pm 1}, e_{1\pm 1}, e_{2\pm 1}, \ldots, e_{r\pm 1}]$ be the representation ring of $(\mathbb{C}^*)^2 \times (\mathbb{C}^*)^r$. Then the weight decomposition of the tangent space $T_p \mathcal{M}(r, n)$ of the variety $\mathcal{M}(r, n)$ at the point $p$ is given by (see e.g. [23])

$$T_p \mathcal{M}(r, n) = \sum_{i,j} e^j e^i \left( \sum_{s \in D_i} l_{D_i(s)+1} a_{D_i(s)} - l_{D_j(s)+1} a_{D_j(s)} \right).$$

For a computation of $d_{v,k}^+$ we choose an arbitrary $(\mathbb{C}^*)^2 \times (\mathbb{C}^*)^r$-fixed point $p$ in $\mathcal{M}(r, n)^{T_{\alpha,\beta}}_{v,k}$. Let $D$ be the corresponding $r$-tuple of Young diagrams. We have

$$d_{v,k}^+ = \sum_{i,j} \sharp \left\{ s \in D_i \left| \begin{array}{l} \theta_j - \theta_i - \alpha l_{D_j(s)} + \beta(a_{D_i(s)}+1) \equiv 0 \mod m \\ \theta_j - \theta_i - \alpha l_{D_j(s)} + \beta a_{D_i(s)} > 0 \end{array} \right. \right\}$$

$$+ \sum_{i,j} \sharp \left\{ s \in D_j \left| \begin{array}{l} \theta_j - \theta_i + \alpha(l_{D_j(s)+1} - a_{D_i(s)}) \equiv 0 \mod m \\ \theta_j - \theta_i + \alpha l_{D_j(s)+1} - \beta a_{D_j(s)} > 0 \end{array} \right. \right\}$$

$$= \sum_{i,j} \sharp \left\{ s \in D_i \left| \begin{array}{l} \theta_j - \theta_i - \alpha l_{D_j(s)} + \beta(a_{D_i(s)}+1) \equiv 0 \mod m \\ \theta_j - \theta_i - \alpha l_{D_j(s)} + \beta a_{D_i(s)} > 0 \end{array} \right. \right\}$$

$$+ \sum_{i,j} \sharp \left\{ s \in D_i \left| \begin{array}{l} \theta_j - \theta_i - \alpha l_{D_j(s)} + \beta(a_{D_i(s)}+1) \equiv 0 \mod m \\ \theta_j - \theta_i - \alpha l_{D_j(s)} + \beta a_{D_i(s)} < m \end{array} \right. \right\}$$

$$= \sum_{i,j} \sharp \left\{ s \in D_i \left| \theta_j - \theta_i - \alpha l_{D_j(s)} + \beta(a_{D_i(s)}+1) \equiv 0 \mod m \right. \right\}$$

$$+ \sum_{i,j} \sharp \left\{ s \in D_i \left| \theta_j - \theta_i - \alpha l_{D_j(s)} + \beta(a_{D_i(s)}+1) \equiv 0 \mod m \right. \right\}.$$ 

It is easy to see that the last sum is equal to zero, thus

$$d_{v,k}^+ = \sum_{i,j} \sharp \left\{ s \in D_i | \theta_j - \theta_i - \alpha l_{D_j(s)} + \beta(a_{D_i(s)}+1) \equiv 0 \mod m \right\}.$$
On the other hand
\[
\dim \mathcal{M}(r, n)_{\alpha, \beta}^{\mathbb{F}^\theta}
= \sum_{i,j} \# \{ s \in D_i | \theta_j - \theta_i - \alpha l_{D_j}(s) + \beta (a_{D_i}(s) + 1) \equiv 0 \mod m \}
+ \sum_{i,j} \# \{ s \in D_j | \theta_j - \theta_i + \alpha (l_{D_i}(s) + 1) - \beta a_{D_j}(s) \equiv 0 \mod m \}
= 2 \sum_{i,j} \# \{ s \in D_i | \theta_j - \theta_i - \alpha l_{D_j}(s) + \beta (a_{D_i}(s) + 1) \equiv 0 \mod m \}.
\]

Hence \( d_{v,k}^+ = \frac{1}{2} \dim \mathcal{M}(r, n)_{\alpha, \beta}^{\mathbb{F}^\theta} = \frac{1}{2} \dim \mathcal{M}(v, w) \). \( \square \)

From Lemmas 2 and 3 it follows that
\[
\mathcal{M}(r, n)_{\alpha, \beta}^{\mathbb{F}^\theta} = L \frac{1}{2} \dim \mathcal{M}(v, w) \mathcal{M}(r, n)_{\alpha, \beta}^{\mathbb{F}^\theta}.
\]

Using the \((\mathbb{C}^*)^2 \times (\mathbb{C}^*)^r\)-action it is easy to get a cell decomposition of the varieties \( \mathcal{M}(r, n)_{\alpha, \beta}^{\mathbb{F}^\theta} \) and \( \mathcal{M}(r, n)_{v, k}^{\mathbb{F}^\theta} \). Therefore
\[
\mathcal{M}(r, n)_{\alpha, \beta}^{\mathbb{F}^\theta} = P_{BM}(\mathcal{M}(r, n)_{v, \alpha, \beta}^{\mathbb{F}^\theta}) \big|_{q = L},
\]
\[
\mathcal{M}(r, n)_{v, k}^{\mathbb{F}^\theta} = P_{q}(\mathcal{M}(r, n)_{v, k}^{\mathbb{F}^\theta}) \big|_{q = L}.
\]

The theorem is proved.

3 Proof of Theorem 1

In this section we prove Theorem 1. First of all, in Sect. 3.1 we remind the reader a notion of a power structure over the Grothendieck ring \( K_0(\nu \mathbb{C}) \). This technique allows us to simplify some combinatorial computations. Then in Sect. 3.2 we review standard combinatorial constructions related to Young diagrams. In Sect. 3.3 we review a connection between Hilbert schemes and quiver varieties and do an important step in the proof of Theorem 1. Instead of considering the \( T_{\alpha, \beta} \)-fixed point set in the Hilbert scheme \((\mathbb{C}^2)^{[n]}\), we first look at the fixed point set of a finite subgroup of \( T_{\alpha, \beta} \). Finally, in Sect. 3.4 we combine everything and prove the theorem.
3.1 Power Structure over $K_0(\nu_C)$

In [10] there was defined a notion of a power structure over a ring and there was described a natural power structure over the Grothendieck ring $K_0(\nu_C)$. This means that for a series $A(t) = 1 + a_1 t + a_2 t^2 + \cdots \in 1 + t \cdot K_0(\nu_C)[[t]]$ and for an element $m \in K_0(\nu_C)$ one defines a series $(A(t))^m \in 1 + t \cdot K_0(\nu_C)[[t]]$ so that all the usual properties of the exponential function hold. We also need the following property of this power structure. For any $i \geq 1$ and $j \geq 0$ we have (see e.g. [10])

$$\left(1 - \frac{1}{m} t^i\right)^j = 1 - \frac{1}{m} t^{j+1}.$$  \hfill (5)

3.2 Cores and Quotients

In this section we review the well known construction of an $m$-core and an $m$-quotient of a Young diagram.

The set $Core_m$ is defined as the set of Young diagrams $Y$ such that for any box $s \in Y$ we have $l_Y(s) + a_Y(s) + 1 \not\equiv 0 \mod m$. For a Young diagram $Y$ let

$$w_i(Y) = |\{(p, q) \in Y | p + q \equiv i \mod m\}|.$$

We remind the reader that we consider a Young diagram as a subset of $\mathbb{Z}^2_{\geq 0}$. Let

$$\Pi_m^{-1} = \left\{ \lambda = (\lambda_0, \lambda_1, \ldots, \lambda_{m-1}) \in \mathbb{Z}^m \begin{array}{l} m-1 \sum_{k=0}^{m-1} \lambda_k = 0 \end{array} \right\}.$$

Define the map $\Psi : Core_m \to \Pi_m^{-1}$ by

$$Core_m \ni Y \mapsto (\lambda_0, \lambda_1, \ldots, \lambda_{m-1}), \lambda_i = w_{i+1}(Y) - w_i(Y).$$

The map $\Psi$ is a bijection (see e.g. [13], Chap. 2.7).

There is also a bijection (see e.g. [13], Chap. 2.7)

$$\Phi : \mathcal{Y} \to Core_m \times \mathcal{Y}^m, \quad \Phi(Y) = (\Phi(Y)_0, \Phi(Y)_1, \ldots, \Phi(Y)_m).$$

We don’t give a construction of this map, we will only list all necessary properties. The diagram $\Phi(Y)_0$ is called the $m$-core of the diagram $Y$ and the $m$-tuple $(\Phi(Y)_1, \Phi(Y)_2, \ldots, \Phi(Y)_m)$ is called the $m$-quotient. The bijection $\Phi$ has the following properties (see e.g. [13], Chap. 2.7):

$$|Y| = |\Phi(Y)_0| + m \sum_{i=1}^{m} |\Phi(Y)_i|;$$  \hfill (6)
\[ w_i(Y) = w_i(\Phi(Y)_0) + \sum_{i=1}^m |\Phi(Y)_i|; \quad (7) \]
\[ \sharp \{ s \in Y | l_Y(s) + a_Y(s) + 1 \equiv 0 \mod m \} = \sum_{i=1}^m |\Phi(Y)_i|. \quad (8) \]

### 3.3 Hilbert Schemes and Quiver Varieties

For an ideal \( I \subset \mathbb{C}[x, y] \) of codimension \( n \) let \( V(I) = \mathbb{C}[x, y]/I \) and \( B_1, B_2 \in GL(V(I)) \) be the operators of the multiplications by \( x \) and \( y \) correspondingly. Let \( i : \mathbb{C} \to V(I) \) be the linear map that sends 1 to the unit in \( \mathbb{C}[x, y] \). Define the map \( f : (\mathbb{C}^2)^{[m]} \to \mathcal{M}(1, n) \) by \( I \mapsto ([B_1, B_2, i, 0]) \). This map is an isomorphism (see e.g. [22]).

For integers \( \mu \) and \( \nu \) let \( \Gamma_{\nu, \mu} \) be the finite subgroup of \( (\mathbb{C}^*)^2 \) defined as \( \Gamma_{\nu, \mu} = \{ (\zeta^{j\nu}, \zeta^{j\mu}) \in (\mathbb{C}^*)^2 | \zeta = \exp(\frac{2\pi i m}{m}) \} \). It is clear that the isomorphism \( f \) transforms the \( T_{\alpha, \beta} \)-action on \( (\mathbb{C}^2)^{[m]} \) to the \( T_{\alpha, \beta}^0 \)-action on \( \mathcal{M}(1, n) \) and the \( \Gamma_{\alpha, \beta} \)-action to the \( \Gamma_{\alpha, \beta}^0 \)-action. Thus, by Lemma 1, we have

\[
((\mathbb{C}^2)^{[m]})_{T_{\alpha, \beta}} = \prod_{v \in \mathbb{Z}^m_{\geq 0}} \mathfrak{M}(v, e_0), \quad ((\mathbb{C}^2)^{[m]})_{\Gamma_{\alpha, \beta}} = \prod_{v \in \mathbb{Z}^m_{\geq 0}} \mathfrak{M}(v, e_0)^{\tilde{\Gamma}_{\alpha, \beta}}, \quad (9)
\]

where by \( e_0 \) we denote the vector \( (1, 0, \ldots, 0) \in \mathbb{Z}^m_{\geq 0} \). Until the end of this section we consider a quiver variety \( \mathfrak{M}(v, e_0) \) as a subset of \( \mathcal{M}(1, \sum v_i) = (\mathbb{C}^2)^{[\sum v_i]} \).

The last factor \( \mathbb{C}^* \) of the product \( (\mathbb{C}^*)^2 \times \mathbb{C}^* \) acts trivially on \( \mathcal{M}(1, n) \), so now we start to consider only the \( (\mathbb{C}^*)^2 \)-action on \( \mathcal{M}(1, n) \).

### 3.4 Proof of Theorem 1

For a vector \( v \in \mathbb{Z}^m_{\geq 0} \) let \( |v| = \sum_{i=0}^{m-1} v_i \). By (9) and Theorem 4, we have

\[
\sum_{n \geq 0} P_q(((\mathbb{C}^2)^{[n]})_{T_{\alpha, \beta}}) t^n = \sum_{v \in \mathbb{Z}^m_{\geq 0}} q^{-\frac{1}{2} \dim \mathfrak{M}(v, e_0)} P_q^{BM}(\mathfrak{M}(v, e_0)) t^{|v|}. \]
If the variety $\mathcal{M}(v, e_0)$ is nonempty, then (see e.g. [23])

$$\dim \mathcal{M}(v, e_0) = 2v_0 - \sum_{i=0}^{m-1} (v_i - v_{i+1})^2. \quad (10)$$

Here we follow the convention $v_m = v_0$. For $\lambda \in \Pi^{m-1}$ let

$$v_0(\lambda) = \frac{1}{2} \sum_{k=0}^{m-1} \lambda_k^2,$$

$$n(\lambda) = m v_0(\lambda) + \sum_{k=0}^{m-2} (m - 1 - k) \lambda_k.$$

Using these notations and formula (10) we get

$$\sum_{v \in Z_{\geq 0}^m} q^{-\frac{1}{2} \dim \mathcal{M}(v, e_0)} p_q^{BM}(\mathcal{M}(v, e_0)) t^{|v|} = \sum_{\lambda \in \Pi^{m-1}} t^{n(\lambda)} \sum_{v \in Z_{\geq 0}^m} p_q^{BM}(\mathcal{M}(v, e_0)) (q^{\frac{1}{m} t})^m (v_0 - v_0(\lambda)).$$

**Lemma 4** For any $\lambda \in \Pi^{m-1}$ we have

$$\sum_{v \in Z_{\geq 0}^m, v_{i+1} - v_i = \lambda_i} p_q^{BM}(\mathcal{M}(v, e_0)) t^{|v|} = \frac{t^{n(\lambda)}}{\prod_{i \geq 1} (1 - q^i t^{mi})^{m-1} (1 - q^{i+1} t^{mi})}.$$

Before a proof of this lemma we introduce a new notation and prove two useful lemmas.

In the proof of Lemma 2 we used the morphism $\pi : \mathcal{M}(r, n) \to \mathcal{M}_0(r, n)$. We have $\mathcal{M}_0(1, n) = S^n(\mathbb{C}^2)$ (see e.g. [22]). Slightly changing notations we denote now by $\pi$ the morphism $\mathcal{M}(1, n) \to S^n(\mathbb{C}^2)$. It can be described explicitly as follows. Let $[(B_1, B_2, i, j)] \in \mathcal{M}(1, n)$. We can make $B_1$ and $B_2$ simultaneously into upper triangular matrices with numbers $\lambda_i$ and $\mu_i$ on the diagonals. The morphism $\pi$ is given by $\pi(B_1, B_2, i, j) = \{ (\lambda_1, \mu_1), \ldots, (\lambda_n, \mu_n) \}$ (see e.g. [22]).

It is useful to note that the subgroups $\Gamma_{\alpha, \beta}$ and $\Gamma_{1,-1}$ of $(\mathbb{C}^*)^2$ coincide, therefore

$$\mathcal{M}(1, n)^{\Gamma_{\alpha, \beta}} = \mathcal{M}(1, n)^{\Gamma_{1,-1}}.$$

For any $\Gamma_{1,-1}$-invariant subset $Z \subset \mathbb{C}^2$ and any vector $\lambda \in \Pi^{m-1}$ let

$$H_{Z, \lambda}(t) = \sum_{v \in Z_{\geq 0}^m, v_{i+1} - v_i = \lambda_i} [\mathcal{M}(v, e_0) \cap \pi^{-1}(S^{|v|} Z)] t^{|v|}.$$
We denote by $\mathbb{C}_x$ the $x$-axis in the plane $\mathbb{C}^2$.

**Lemma 5** For any $\lambda \in \Pi^{m-1}$ consider the unique diagram $Y_\lambda \in \text{Core}_m$ such that $\Psi(Y_\lambda) = \lambda$. Then we have

$$H_{\mathbb{C}_x, \lambda}(t) = \frac{t|Y_\lambda|}{\prod_{i \geq 1} (1 - \|t^{mi}\|)^{m}}.$$  \hfill (11)

**Proof** The set of fixed points of the $(\mathbb{C}^*)^2$-action on $M(1, n)$ is parametrized by the set of Young diagrams $Y$ such that $|Y| = n$. Let $p$ be the fixed point corresponding to a Young diagram $Y$, then, by (4), we have

$$T_p(M(1, n)) = \sum_{s \in Y} (t_1^{l_Y(s)} t_2^{a_Y(s)+1} + t_1^{l_Y(s)+1} t_2^{-a_Y(s)}).$$ \hfill (12)

We choose $\gamma \gg 1$ and for each point $p \in M(v, e_0)(\mathbb{C}^*)^2$ we define the attracting set $C_p$ as follows

$$C_p = \left \{ z \in M(v, e_0) \left| \lim_{t \to 0, t \in T_{1, -\gamma}} t z = p \right. \right \}.$$ 

Clearly, if $z \in \mathbb{C}_x$, then $\lim_{t \to 0, t \in T_{1, -\gamma}} t z = 0$, and if $z \in \mathbb{C}^2 \setminus \mathbb{C}_x$, then $t z$ goes to infinity. By [1, 2], the sets $C_p$ form a cell decomposition of $M(v, e_0) \cap \pi^{-1}(S|v| \mathbb{C}_x)$. Using (12) we obtain

$$\left[ M(v, e_0) \cap \pi^{-1}(S|v| \mathbb{C}_x) \right] = \sum_{s \in Y} \mathbb{L}_{[s \in Y] l_Y(s) + a_Y(s) + 1 \equiv 0 \text{ mod } m}. \hfill (13)$$

The formula (11) follows from (13) and properties (6), (7) and (8). \hfill $\square$

**Lemma 6** For any $Y \in \text{Core}_m$ we have $|Y| = n(\Psi(Y))$.

**Proof** Consider the quiver variety $\mathcal{M}(w(Y), e_0)$. From the properties of the bijection $\Phi$ it follows that if $Y'$ is a Young diagram such that $|Y'| = |Y|$ and $w(Y) = w(Y')$, then $Y' = Y$. Thus, the $(\mathbb{C}^*)^2$-fixed point set in $\mathcal{M}(w(Y), e_0)$ consists of only one point. Using the Bialynicki-Birula theorem we can construct a cell decomposition of $\mathcal{M}(w(Y), e_0)$ and it is easy to see that the unique cell has dimension 0. Therefore, $\mathcal{M}(w(Y), e_0)$ is just a point. By (10), $w_0(Y) = v_0(\Psi(Y))$ and clearly $|Y| = n(\Psi(Y))$. \hfill $\square$

**Proof of Lemma 4** For $\lambda = 0$ this lemma was proved in [11].

Since $[\mathcal{M}(v, e_0)] = P^{BM}_{q} (\mathcal{M}(v, e_0))|_{q=\mathbb{L}}$, it is sufficient to prove that

$$\sum_{v \in Z_{>0}^m \ni \sum_{i} v_i = \lambda} \left[ \mathcal{M}(v, e_0) \right] ^{l[v]} = \prod_{i \geq 1} (1 - \|t^{mi}\|)^{m-1} (1 - \|t^{i+1} \|)^{m-1}.$$
The $\Gamma_{1,-1}$-action on $\mathbb{C}^2 \setminus \mathbb{C}_x$ is free. Therefore, if the intersection of $\mathcal{M}(v, e_0)$ with $\pi^{-1}(S^{|v|}(\mathbb{C}^2 \setminus \mathbb{C}_x))$ is nonempty, then $v_0 = v_1 = \cdots = v_{m-1}$. We get

$$H_{\mathbb{C}^2, \lambda}(t) = H_{\mathbb{C}_x, \lambda}(t) H_{\mathbb{C}^2 \setminus \mathbb{C}_x, \theta}(t).$$ (14)

We denote by $O$ the origin of $\mathbb{C}^2$. Let

$$H_O(t) = \sum_{n \geq 0} \left[ |\mathcal{M}(1, n) \cap \pi^{-1}(S^n(O))| \right] t^n.$$

From [11] (see Theorem 1) it follows that

$$H_{\mathbb{C}^2 \setminus \mathbb{C}_x, \theta}(t) = H_O(t^{-m})|_{(\mathbb{C}^2 \setminus \mathbb{C}_x) / \Gamma_{1,-1}}.$$ (15)

It is easy to check that $[(\mathbb{C}^2 \setminus \mathbb{C}_x) / \Gamma_{1,-1}] = \mathbb{L}^2 - \mathbb{L}$. Therefore we have

$$H_{\mathbb{C}^2 \setminus \mathbb{C}_x, \theta}(t) = \left( \prod_{i \geq 1} \frac{1}{(1 - \mathbb{L}^i - 1 t^{mi})} \right)^{\mathbb{L}^2 - \mathbb{L}} \text{ by (5)} \cdot \left( \prod_{i \geq 1} \frac{1 - \mathbb{L}^i t^{mi}}{1 - \mathbb{L}^i + 1 t^{mi}} \right).$$ (15)

If we combine formulas (11), (14) and (15) and also Lemma 6, we get the proof of the lemma. □

Using Lemma 4 we get

$$\sum_{\lambda \in \Pi^{m-1}} t^{n(\lambda)} \sum_{\nu \in \mathbb{Z}_{\geq 0}^m} p_{\nu} \left( \mathcal{M}(v, e_0) \right) \left( q^{\nu_0 - v_0(\lambda)} \right) = \left( \prod_{i \geq 1} \frac{1}{(1 - t^{mi}) \nu - 1 (1 - q t^{mi})} \right) \left( \sum_{\lambda \in \Pi^{m-1}} t^{n(\lambda)} \right).$$

By Lemma 6, $\sum_{\lambda \in \Pi^{m-1}} t^{n(\lambda)} = \sum_{Y \in \text{Core}_m} t^{|Y|}$. We have (see e.g. [11])

$$\sum_{Y \in \text{Core}_m} t^{|Y|} = \prod_{i \geq 1} \frac{(1 - t^{mi})^m}{(1 - t^i)}.$$ 

This completes the proof of the theorem.

4 Proofs of Theorems 2 and 3

Here we prove two combinatorial identities from Sect. 1.1.
4.1 Proof of Theorem 2

Consider the \((\mathbb{C}^*)^2\)-action on \(((\mathbb{C}^2)[n])^{T\alpha,\beta}\). Let \(p \in (\mathbb{C}^2)[n]\) be the fixed point corresponding to a Young diagram \(Y\). By (4), the weight decomposition of \(T_p(((\mathbb{C}^2)[n])^{T\alpha,\beta})\) is given by

\[
T_p(((\mathbb{C}^2)[n])^{T\alpha,\beta}) = \sum_{s \in Y} \alpha(l_Y(s) + 1) t_1^{-a_Y(s)} t_2^{-a_Y(s)} + \sum_{s \in Y} \beta(a_Y(s) + 1) t_1^{-l_Y(s)} t_2^{-a_Y(s)} + 1. \tag{16}
\]

Let \(\gamma\) be a big positive integer. By [1, 2], the variety \(((\mathbb{C}^2)[n])^{T\alpha,\beta}\) has a cellular decomposition with the cells \(C_p = \{ z \in (((\mathbb{C}^2)[n])^{T\alpha,\beta}) | \lim_{t \to 0, t \in T_1, \gamma tz = p} \}\). By (16), we have \(\dim C_p = \# \{ s \in Y | \alpha l_Y(s) = \beta(a_Y(s) + 1) \}\). Thus, we have

\[
\sum_{n \geq 0} P_q(((\mathbb{C}^2)[n])^{T\alpha,\beta}) t^n = \sum_{Y \in \mathcal{Y}} q^{\# \{ s \in Y | \alpha l_Y(s) = \beta(a_Y(s) + 1) \}} |Y|. \]

Now Theorem 2 follows from Theorem 1.

4.2 Proof of Theorem 3

In [12] it is proved that the set of irreducible components of the variety \(((\mathbb{C}^2)[n])^{T_1,1}\) is parametrized by partitions \(\lambda\) such that \(\frac{\lambda_1(\lambda_1-1)}{2} + |\lambda| = n\). The Poincaré polynomial of the irreducible component corresponding to a partition \(\lambda\) is equal to (see [12])

\[
\prod_{i \geq 1} \left[ \frac{\lambda_i - \lambda_i + 2 + 1}{\lambda_{i+1} - \lambda_i + 2} \right]_q.
\]

Combining this fact with Theorem 1 we get the proof of Theorem 3.

5 Proof of Theorem 5

Let \(\alpha + \beta = m\). Similar to Lemma 1 we have the decomposition

\[
\mathcal{M}(r, n)^{T\alpha,\beta} = \bigcup_{v \in \mathbb{Z}^m_{>0} \atop |v| = n} \mathcal{M}(v, \mu), \tag{17}
\]
and the $T_{\alpha, \beta}^\omega$-action on the left-hand side of (17) corresponds to the $\tilde{T}_{\alpha, \beta}$-action on the right-hand side. Using Theorem 4 we get

$$\sum_{n \geq 0} h_0(\mathcal{M}(r, n)^{T_{\alpha, \beta}^\omega}) q^n = \sum_{v \in \mathbb{Z}_{\geq 0}^m} \dim H^{BM}_{1/2} M_{(v, \mu)}(\mathcal{M}(v, \mu)) q^{\|v\|}.$$ 

In [20] it is proved that the space $\bigoplus_{v \in \mathbb{Z}_{\geq 0}^m} H^{BM}_{1/2} M_{(v, \mu)}(\mathcal{M}(v, \mu))$ is an irreducible highest weight representation of $\widehat{sl}_m$ with the highest weight $\mu$. This completes the proof of Theorem 5.
