(Dated: April 1, 2022)

The response to a probe laser beam of a suspended, misaligned and detuned optical cavity is examined. A five degree of freedom model of the fluctuations of the longitudinal and transverse mirror coordinates is presented. Classical and quantum mechanical effects of radiation pressure are studied with the help of the optical stiffness coefficients and the signals provided by an FM sideband technique and a quadrant detector, for generic values of the product $\pi T$ of the fluctuation frequency times the cavity round trip. A simplified version is presented for the case of small misalignments. Mechanical stability, mirror position entanglement and ponderomotive squeezing are accommodated in this model. Numerical plots refer to cavities under test at the so-called Pisa LF facility.

I. INTRODUCTION AND NOTATION

Optical cavities are generally studied by assuming a single mode excitation and ignoring the photon scattering by mirror reflections into other modes. A single mode description is no more reliable when a slight misalignment is sufficient to excite different modes. This situation is met in almost concentric or plane-parallel or confocal configurations. In other cases the weak amplitudes of modes falling outside the resonance bandwidth are of interest. For example, the sensitivity of interferometers with cavities placed in their arms depends on the contribution of higher modes as well as the error signals used for longitudinal and angular alignments.

Optical cavities are generally stabilized, in length, by the Drexer-Pound (D-P) technique \cite{1} working with odd harmonics of the phase modulated laser beam.

In order to deal with a large variety of situations the model discussed in this paper accounts for misalignment, detuning and a generic spectrum of harmonics. Faced with the possibility of working with approximate expressions it has been preferred to simplify exact solutions at the end of the calculation. This option avoids difficulty of making adequate approximations in presence of a large number of parameters.

This strategy can be useful for the design studies necessary for the development of future gravitational antennas. It gives the possibility to investigate noise contributions coming from all optical and mechanical degrees of freedom. It can be also used for studying instabilities, optical spring effect, entanglement and radiative pressure squeezing associated to both axial and angular fluctuations for any degree of detuning, misalignment and mismatch.

The present work grew up from the study of short and large spot size resonators \cite{2} implemented at LFF (Low Frequency Facility \cite{3}) a facility dedicated to testing new mechanical suspensions, controls and mirrors for the VIRGO interferometer gravitational antenna, and studying the effects of radiation pressure, mirror and suspensions thermal noise.

Main features of the LFF are the use of suspended mirrors and the possibility of confining large section cavity modes. The mirrors hang from multipendula which guarantee a drastic reduction of the seismic noise above the resonance frequencies of the mechanical modes. The phase-modulated light reflected by the cavity is used by a Pound-Drever apparatus \cite{1} both for stabilizing the cavity length, and measuring the noise spectrum. Several papers analyzed the dynamic and the alignment of cavities sharing some of the LFF features \cite{4,5,6}. Numerous specialized studies have been produced by research groups of VIRGO, LIGO, TAMA and GEO projects \cite{7}.

Suspended cavities have been analyzed by several authors in different contexts, all sharing the common feature of using a system of Langevin equations for both the mechanical and electromagnetic modes. The coupling of cavity and mechanical modes is represented by suitable potentials \cite{8,9} leading to a complex interplay between cavity mode amplitudes, mirror positions and orientation fluctuations. In this paper the resonator is regarded as a mechanical Langevin system driven by thermal sources and shot noise. This is done by-passing the Hamiltonian approach and hiding the optical modes fluctuations into the mechanical ones by generalizing an approach introduced in \cite{10}. So doing, the Langevin system contains ponderomotive terms, connected with the classical part of the laser beam and the shot noise. The seismic noise affecting the mechanical system has been neglected. Once known, its local spectral density can be easily added to the thermal one.

Thermal motion of mechanical oscillators has been modelled as standard Brownian motion \cite{11}, possibly corrected by Diosi for preserving the quantum mechanical
drives the cavity. The front
frequency Λ by the modulator
in the present paper. The laser beam is phase modulated at

FIG. 1: Typical optical layout of the apparatus examined
in the present paper. The laser beam is phase modulated at
frequency Λ by the modulator M(Λ). The modulated beam
drives the cavity. The front M1 and back M2 mirrors are
suspended to multipendulum chains. The beam reflected by
the front mirror is sent to a photodetector PD, and the pho
todetection signal is demodulated before going to a spectrum
analyzer. The same signal is sent to a control system (not
shown) which provides a feedback signal applied to mirror
M1. The noise of the system is studied by spectral analysis.

commutation relations [12], or by non-Lindblad master
Equations (ME) [13,14]. Accordingly, in the present model
thermal correlation functions have been introduced.

The quantum field fluctuations (shot-noise) are ac-
counted for by splitting each mode amplitude in a classi-
cal and a quantum parts [8,15] and relying on the input-
output theory [16].

Radiation pressure can lead to mechanical instabilities,
as predicted by Braginsky and Manukin [17]. Acting on
the suspended mirrors it provides a spring action which
either depresses or reinforces any perturbation [10,18].
It may also be used to mechanically entangle
the two mirrors [21] or to enhance the squeezing of the output
field [22].

In Fig. 1, it is represented the typical optical layout of the
apparatus that will be examined. Main features of the
present model are: i) the multimode description of the
cavity field; ii) the inclusion of radiation pressure and
shot noise terms; iii) the description of suspensions and
mirrors in terms of mechanical modes.

Here and in the following J = 1, 2 labels the mirror,
x the axial and q = y, z the transverse coordinates. The
analysis is focused on the fluctuations of the J’s mirror
orientation (δθ_{J,q}) and displacements (δx_{J}, δξ_{J,q}),
combined in the parameters

\[ \delta \psi_J = (-1)^J 2k^J \delta x_J \]
\[ \delta \alpha_{J,q} = i (-1)^J \sqrt{2k^J} w_J \left( \delta \theta_{J,q} - \frac{\delta \xi_{J,q}}{R_J} \right) \]

(1)

with k^J laser wavenumber, w_J spot size, R_J mirror cur-
vature radius and \( \delta \Omega_J = (\delta \Omega_J \times \hat{q}) \cdot \hat{q} \) depending on the
rotation’s angles \( \delta \Omega_J \). In addition the mirror vibrations
are accounted for by introducing matrices C_{J,q} and func-
tions \( \delta r_{J,q} \) representing respectively profile and amplitude
of the s-th vibrational mode of the J-th mirror.

The radiation pressure force and torques are linearized
with respect to the set \( \{ \delta \alpha_{J,q} \} \) of transverse mirror
coordinates by introducing optical stiffness coefficients.
Hence, the Fourier transforms \( \{ \delta \alpha_{J,q} \} \) satisfy Langevin
equations with driving forces proportional to these quan-
tities. They become important in proximity of the sus-
pensions and mirror mechanical resonances. These stiff-
ness coefficients are in general frequency dependent for
the presence of the phase factor \( e^{i \pi \tau} \), with \( \tau \) the cavity
round trip.

A vector approach has been adopted by representing
the amplitudes of the excited cavity modes by a column
vector \( \mathbf{a} \) while the mismatch and misalignment of the
input beam is accounted for by a vector \( \mathbf{v} \). The vari-
ous quantities \( O \) used for describing the system dynamics
(e.g. the force acting on a given suspension mode) have
been expressed in forms like \( O = v^T \cdot O \cdot v \) with \( O \)
a matrix representation of the quantity itself. In analogy
with quantum mechanics \( O \) is seen as the matrix represen-
tation of an operator \( O \) corresponding to the quantity
of interest, and \( v \) as the quantum state of the resonator.

For evaluating spectral densities it has been introduced
the symbol \( \dagger \) which is defined by its action on frequency
dependent quantities:

\[ f^\dagger(\omega) \equiv f^*( -\omega^* ) \]

and the shorthands

\[ \Im \{ f(\omega) \} = \frac{1}{2i} ( f(\omega) - f^\dagger(\omega) ) \]
\[ \Re \{ f(\omega) \} = \frac{1}{2} ( f(\omega) + f^\dagger(\omega) ) \]

The same \( \dagger \) applied to a frequency dependent matrix
transforms \( \mathbf{O}(\omega) \) into \( \mathbf{O}^\dagger(\omega) = \mathbf{O}^\dagger(-\omega^*) \).

The summation symbol is omitted when applied to ex-
pressions containing a repeated index.

The paper is organized in seven sections. Section II is
dedicated to the optical modes excited in a cavity with
moving mirrors, and to the susceptivities relative to the
noise sources of the suspensions, mirror vibrations and
shot noise. The dynamic of the mechanical components
(mirrors and suspensions) is discussed in Sec. III while
the Drever-Pound and quadrant detector signals are an-
alyzed in Sec. IV.

The results obtained in these sections are combined in
Sec. V where a five degrees of freedom model of the cav-
itvity, including radiative pressure and torques, is presented.
The model is linearized for small misalignments and res-
onance enhanced effects are discussed in Sec. VI where
the cavity is examined as a bipartite system. In this
context ponderomotive squeezing of the output field and
entanglement of two mirror modes are discussed. The
manuscript is completed by six mathematical appendices.
The first three of them give the expressions for the stiffness and the Drever-Pound signal matrices together with their simplified expressions in case of small misalignment and mismatch. The last ones are dedicated to thermal and shot-noise sources, and their mutual correlations.

II. CAVITY FIELD

A suspended cavity of length $L$ excited by a time harmonic field is described by a superposition of Hermite-Gauss modes $u_{\lambda}(\vec{r},x)$

$$e^{-i\omega t} \sum_{\sigma=\pm} \exp\left[i\lambda^\ell \frac{r^2}{2R(x)}\right] a_{\lambda}^{(\sigma)}(x,t) u_{\lambda}(\vec{r},x).$$

with $\omega$ the laser frequency, $\sigma = +$ for a wave travelling from mirror 1 toward 2 and $-$ contrariwise. The wavefront curvature $R(x)$ is matched to the mirror’s curvature: $R(0) = R_1 < 0$, $R(L) = R_2 > 0$. Each mode is labeled as usual by a couple of integer numbers $(\lambda_{\nu}, \lambda_z) \equiv \lambda$. Here and in the following $x$ stands for the optical axis coordinate and $(y,z) \equiv \vec{r}$ are the two transverse ones. Each mode $u_{\lambda}$ is taken with a fixed normalization on the transverse section and without phase factors,

$$a_{\lambda}^{(\sigma)}(x,t) = \frac{\lambda}{\sqrt{\pi \sigma}} e^{i\lambda^\ell \frac{r^2}{2R(x)}} \left| a_{\lambda}^{(\sigma)}(x,t) \right|$$

where $\phi (x) = \arctan \left( \frac{x-x_0}{b} \right)$ is the phase delay of the Gaussian fundamental mode with respect to a plane wave, $x_0$ being the distance of the waist from the input mirror and $b$ the confocal parameter. The field is propagated outside the resonator by passing through the different optical components met on the way toward the laser source and the photodetector which provides the error signal.

The laser beam incident on (input) mirror 1 has been split it in a classical and in a quantum term:

$$E^{in}(\vec{r},t) = e^{-i\omega t} E (1 + \mu^t(t)) u_{in}(\vec{r}) + \delta\tilde{a}^{SN}$$

being

$$E = \sqrt{\frac{P}{h\omega}} = 2.5 \times 10^9 \left( \frac{P}{1W} \right)^{1/2} \left( \frac{\lambda^\ell}{1\mu} \right)^{1/2} \text{Hz}^{1/2}$$

the mean amplitude, and $\mu^t$ the relative amplitude fluctuations. Effects of the laser linewidths have been ignored.

Misalignment and mismatch effects between the input beam and the cavity are taken into account by writing $u_{in}(\vec{r})$ as a superposition of cavity modes, namely

$$u_{in}(\vec{r}) = u_{\lambda} u_{\lambda}(\vec{r}).$$

The structure of the expansion coefficients is factorized in a product of Hermite polynomials

$$\delta_{\nu} \delta_{\nu} H_{\lambda_{\nu}} \frac{\delta^{\nu-1}_{\nu} \nu^{\nu-1}_{\nu} \nu^{\nu-1}_{\nu}}{\sqrt{2\lambda_{\nu} + \lambda_1 \lambda_2}}$$

depending on the misalignment $\nu$ and mismatch $\delta_{\nu}$ parameters defined respectively by

$$\nu = -i \frac{k^l w_1}{\sqrt{2}} \left( \theta_q - \frac{\varepsilon_q}{Q_q} \right)$$

$$\delta_q = \sqrt{1 + \frac{2}{k^l w_1^2} \left( Q_q - Q_1^1 \right)}.$$  

For a perfect matching $\nu = 0$ and $\delta = 0$. Here $Q_1$ is the complex curvature radius of the cavity mode evaluated at the input mirror, while $Q_q$, $\theta_q$ and $\varepsilon_q$ stand for the curvature radius, angular and transverse misalignment of the input beam.

The modal expansion (2) will be used in the following for representing the cavity fields in correspondence of the two mirrors as column vectors $\mathbf{v}$ with components $v_{\lambda}$. So doing the multiplication of $u(\vec{r})$ by a function $w(\vec{r})$ will be represented by the product $\mathbf{w} \cdot \mathbf{v}$ of $\mathbf{v}$ by a matrix $\mathbf{w}$.

The coupling of the cavity with the universe modes through the partially transmitting mirrors introduces the quantum noise contribution $\delta\tilde{a}^{SN}(t)$ of Eq. (2)

$$[\delta\tilde{a}^{SN}(t), \delta\tilde{a}^{SN}(t')] = \delta^{(3)}(t-t')$$

It can be expanded as a superposition of delta-correlated operators $\delta\tilde{a}^{SN}(t)$,

$$\delta\tilde{a}^{SN}(t) = \delta\tilde{a}^{SN}(t) u_{\lambda}(\vec{r}).$$

Before arriving at the mirror the excitation beam is passed through a phase modulator represented by the phase factor

$$F = e^{iM \sin(\lambda t)} = e^{-ipM} J_p(M)$$

with $J_p(M)$ the p-th Bessel function of argument $M$. The input modulation $F$ modifies the laser excited amplitude $a_{\lambda}$ into a sum of harmonics varying on the time scale of the suspension fluctuations,

$$a_{\lambda} = J_p e^{-ipM} a_{\lambda p}$$

while leaving the noise unaffected.

A. Cavity fluctuations

Owing to the fluctuations of the suspensions the mirror orientations change slowly in time by undergoing torsions $\delta\Omega_J (t)$, tiltings $\delta\Omega_J (t)$ and transverse displacements $\delta\varepsilon_J (t)$. The mirror can rotate also around the optical axis, but this motion is uncoupled to the cavity field in the linear approximation.
The mirror motions separate into fluctuating and average components, the latter ones setting the reference frame for the vector representation. So doing the average misalignment and displacements will be included in those relative to the input beam, which will be represented by a unit amplitude vector \( \mathbf{v}_J \)

\[
\mathbf{v}_1 = \mathbf{v}, \quad \mathbf{v}_2 = \Phi \hat{\mathbf{z}} \cdot \mathbf{v}
\]

Here \( \delta x_1(t) \) is the deviation of the center from the positions at rest \( x_1(t) = 0 + \delta x_1(t) \). \( \delta u^{DEF}_1 (\mathbf{r}, t) \) is the tiny deformation of the mirror surface represented by the matrix \( \delta \varsigma_1(t) \) of components

\[
\delta \varsigma_{1\lambda\lambda'} (t) = 2k^j \int u_\lambda (\mathbf{r}) \delta u_1^{DEF} (\mathbf{r}, t) u_{\lambda'} (\mathbf{r}) d^2r
\]

Expanding further \( \delta u_1^{DEF} \) into mirror modes \( \delta \varsigma_1(t) \) becomes a superposition

\[
\delta \varsigma_1(t) = \delta \varsigma_{1s}(t) \varsigma_{1s}
\]

of matrices \( \varsigma_{1s} \) times fluctuating amplitudes \( \delta \varsigma_{1s}(t) \) driven by radiation pressure and thermal noise.

Although the frequencies of the mirror acoustic modes are very large, the tails of their spectra contribute to the low frequency thermal noise of the interferometers as recently reported by \cite{23, 24}. Levin \cite{26} has approximated, with those relative to the input beam, which will be represented by a unit amplitude vector \( \mathbf{v}_J \)

\[
\mathbf{v}_1 = \mathbf{v}, \quad \mathbf{v}_2 = \Phi \hat{\mathbf{z}} \cdot \mathbf{v}
\]

with \( \Phi \) a diagonal matrix of components \( \Phi_\lambda = e^{-i2(\omega_\lambda + \lambda_\lambda + 1)\phi_c} \) and \( \phi_c = \phi (L) - \phi (0) \) the single-trip phase delay of the Gaussian fundamental mode. Accordingly in the following the parameters \( \delta \alpha_{Jq} \) (see Eq. \textbf{11}) will be small fluctuating quantities.

The reflection at mirror 1 induces the transformation \( u_\lambda a_\lambda^{-} = r_1 u_\lambda a_\lambda^{+} \) with \( r_1(t) \) the phase factor

\[
r_1 = r_1 \exp \left[ -ik^j \delta \varsigma^2_1 R_1 - i2k^j \delta x_1 - i2k^j \delta u_1^{DEF} + i2k^j \left( \delta \Omega_1 \times \mathbf{x} - \delta \varsigma^2_1 R_1 \right) \cdot \hat{\mathbf{r}} \right]. \tag{8}
\]

Accordingly, ignoring the quadratic expression \( k^j \delta \varsigma^2_1 R_1 \) the phase factor \( r_1 \) (Eq.\textbf{13}) is represented in vector form by

\[
r_1 e^{-i(2k^j \delta x_1 + \delta \varsigma_1 - \delta \alpha_1)} \cdot D_1 (-\delta \alpha_1) \tag{12}
\]

with \( \delta \alpha_1 = (\delta \alpha_{1y}, \delta \alpha_{1z}) \) the combination of rotation and displacement defined by Eq. \textbf{11} and \( D_1 \) the displacement operator

\[
D_1 (-\delta \alpha_1) = \exp \left( -i \alpha_{1y} B_{y}^{+} + i \alpha_{1z} B_{z}^{+} \right)
\]

acting on the functions of the transverse coordinates. The operators \( B_y \) and \( B_z \) act on the mode functions \( u_\lambda \) as typical annihilation operators, \( B_{u_n} = \sqrt{n} u_{n-1} \), and this is the reason why \( D \) has been called a displacement operator.

Next, the propagation from the input mirror to the opposite one is described by

\[
e^{ik^jL} \left( \hat{D}_I \Phi \right)^\frac{1}{2}
\]

(13)

with \( \hat{D}_I = e^{-\frac{i}{\hbar} \hat{\mathbf{x}} \cdot \hat{\mathbf{r}}} \) the delay operator by the cavity round-trip time \( t \). Next combining \textbf{12} with \textbf{13} a round trip is represented by

\[
R e^{-i \psi - i \phi_{1, cav}} \left( \hat{D}_I \Phi \right)^\frac{1}{2} e^{-i \delta \varsigma_1} \cdot D_2 (-\delta \alpha_2) \left( \hat{D}_I \Phi \right)^\frac{1}{2} e^{-i \delta \varsigma_1} \cdot D_1 (-\delta \alpha_1)
\]

(14)

where \( \psi \) is the detuning phase (\( \psi > 0 \) for a cavity shorter than the closest resonance length), \( R = r_1 r_2 = e^{-F/\tau} \) with \( F \) the cavity finesse, and \( \delta \psi_{1, cav} \) the accumulated phase shift, positive for decreasing cavity length,

\[
\delta \psi_{1, cav} (t) = \delta \psi_1 (t - \tau) + \delta \psi_2 \left( t - \frac{\tau}{2} \right)
\]

with \( \delta \psi_J = -(-1)^J 2k^j \delta x_J \). Next, in view of the small-ness of \( \delta \psi_{1, cav}, \delta \alpha_J \) and \( \delta \varsigma_J \) \( D_{1,2} \) and \( e^{-i \delta \psi_{1, cav}} \) can be linearized thus obtaining for the round-trip transformation

\[
e^{-i \psi} R \Phi \left( \hat{D}_I - i \tilde{\mathbf{X}} \cdot \delta \alpha_{J, cav} - i \delta \varsigma_{J, cav} \right) \tag{14}
\]

Here \( \tilde{\mathbf{X}} \cdot \delta \alpha_{J, cav} \) indicates the sum \( \tilde{\mathbf{X}}_i (\delta \alpha_{J, cav})_i \) and two
vectors 

$$\mathbf{x} = (1, X_y, X_z, Y_y, Y_z)$$

$$\delta \alpha_{J,Cav} = (\delta \psi_{J,Cav}, \delta \alpha''_{J,Cav}, \delta \alpha'_{J,Cav}, \delta \alpha'_{J,Cav}, \delta \alpha''_{J,Cav})$$

collect the phase quadratures $X_q = B_q + B_q^\dagger$, $Y_q = i(B_q - B_q^\dagger)$ and the combinations

$$\delta \alpha_{1q,Cav}(t) = \delta \alpha_1 - e^{i\phi_2} \delta \alpha_2 \left(t - \frac{T}{2}\right)$$

($\alpha'$ and $\alpha''$ are the real and imaginary part of $\alpha$ respectively.

Analogously for $\delta \kappa_{J,cav}$

$$\delta \kappa_{1,cav}(t) = \zeta_{J}\delta \kappa_{J}(t - \tau) + \Phi^{-\frac{1}{2}} \cdot \zeta_{2s'} \cdot \Phi^{\frac{1}{2}} \delta \xi_{2s'} \left(t - \frac{T}{2}\right)$$

The amplitude $\alpha'_{\lambda_0,\lambda_1}(t)$ of the $\lambda_0,\lambda_1$-th mode is propagated back and forth the cavity. The fraction $t_1$ is injected into the Fabry Perot through mirror 1 at time $t$ and, propagates toward and is reflected by mirror 2 at $t + \frac{T}{2}$ and again by 1 at $t$. Hence, summing over the sequence of round-trips, the field $a_J$ incident on the $J$-th mirror reads

$$a_J = e^{i\phi_1} \hat{G}_J \cdot \mathbf{v}_J \cdot F + \delta \hat{a}^{SN}$$

with $F = t_1 \mathbf{E}$ and

$$\hat{G}_J = \frac{1}{1 - Re^{-i\mathbf{v} \cdot \delta \alpha_{J,Cav} - i \delta \kappa_{J,Cav}}}$$

For very small $\delta \alpha_{J,Cav}$ and $\delta \kappa_{J,Cav}$ first-order perturbation theory can be used. On the other hand assuming $\psi_1$ either Hermite or Laguerre-Gauss modes the various terms of the perturbation $\mathbf{x} \cdot \delta \alpha_{J,Cav} + \delta \kappa_{J,Cav}$ do not couple the respective degenerate modes. Hence, the Green operator $\hat{G}_J$ can be expressed as

$$\hat{G}_J \simeq \hat{G} - i \hat{E} \cdot \delta \alpha_{J,Cav} - i \hat{E} \cdot \delta \hat{G}^{DEF}$$

where the first term on the right is a static propagator, the second the contribution of the linearized motion of the mirrors and the third one describes the mirror deformations,

$$\hat{G} = (1 - Re^{-i\mathbf{v} \cdot \hat{D}_f})^{-1}$$

$$\hat{E} = e^{-i\mathbf{v} \cdot \hat{R} \hat{G} \cdot \hat{E} \cdot \hat{G}}$$

$$\delta \hat{G}^{DEF} = e^{-i\mathbf{v} \cdot \hat{R} \hat{G} \cdot \hat{E} \cdot \delta \kappa_{J,Cav} \cdot \hat{G}}$$

Next, the contributions of the shot noises entering the cavity through mirror $J$ has been split as $\delta \hat{a}^{SN} = \delta \hat{a}_1^{SN} + t_2T_1^{-1} \delta \hat{a}_2^{SN}$, so that the same approximation of Eq. 18 applies and

$$a_J = a_{0,J} + \delta a_J + \delta \hat{a}^{SN}$$

Here $\delta a_J$ is fluctuating with the cavity geometry and laser intensity, while $a_{0,J}$ does not depend on it and on shot noise,

$$a_{0,J} \approx \mathcal{E} \hat{G} \cdot \mathbf{v}_J \cdot F$$

$$\delta a_J \approx \mathcal{E} \left(\mu^J \hat{G} - i \hat{E} \cdot \delta \alpha_{J,Cav} - i \hat{G} \cdot \delta \hat{G}^{DEF} \right) \cdot \mathbf{v}_J \cdot F$$

$$\delta \hat{a}^{SN} = t_1 \hat{G} \cdot \left(\delta \hat{a}_1^{SN} + \frac{t_2}{t_1} \delta \hat{a}_2^{SN} \right)$$

Further, the relation $\hat{D}_f \cdot e^{-ipM} = e^{-ipM} \cdot e^{ipM} \hat{D}_f$ implies $\hat{G} \cdot e^{-ipM} = e^{-ipM} \hat{G}_p$ with the suffix $p$ indicating that $R$ has been replaced by $R_P = e^{ip\mathbf{R} \cdot \mathbf{R}}$. Then, the factor $e^{-ipM}$ contained in the function $F$ (see Eq. D) can be displaced from the right to the left side of the above expressions by adding the suffix $p$ to the various Green’s functions. Hence

$$a_J = e^{-ipM} \left(a_{0,J} + \delta \hat{a}_J \right) + \delta \hat{a}^{SN}$$

where

$$a_{0,J} = \mathcal{E} J_p \cdot \mathbf{G}_p \cdot \mathbf{v}_J$$

$$\delta a_J \approx \mathcal{E} \left(\mu^J \hat{G}_p - i \hat{E} \cdot \delta \alpha_{J,cav} - i \hat{G}_p \cdot \delta \hat{G}^{DEF} \right) \cdot \mathbf{v}_J$$

Analogously for the output field $\hat{G}_J$

$$a_{OUT} \approx t_1 \mathcal{E} J_p \cdot \mathbf{G}_p \cdot \mathbf{v}_1$$

$$\delta \hat{a}^{OUT}_{SN} = t_1 \left(\delta \hat{a}_1^{OUT} + \frac{t_2}{t_1} \delta \hat{a}_2^{SN} \right)$$

where $\mathbf{G}_p \cdot \hat{G} = \hat{G} - r_1/T^2$.

III. RADIATION PRESSURE AND TORQUE

Bouncing back and forth the two mirrors the laser and shot noise fields exert a radiation pressure resulting in an axial force directed along the optic axis $\hat{x}$ and a torque parallel to their surfaces, proportional to the total intensity $\mathbf{a}_J \cdot \mathbf{a}_J$ and moments $\mathbf{a}_J \cdot \mathbf{X}_q \cdot \mathbf{a}_J$. They split into classical $F_{J,rp}$, $T_{J,rp}$ and quantum $F_{J}^{SN}$, $T_{J}^{SN}$ components respectively given by

$$F_{J,rp} = (-1)^J \mathcal{E}^2 \frac{2 \mathcal{R} J \cdot \mathbf{h} \cdot \mathbf{F}_J \cdot \mathbf{h} \cdot \mathbf{F}_J \cdot \hat{x}}{2 \sqrt{2}} \mathbf{F}_J$$

$$T_{J,rp} = (-1)^J \mathcal{E}^2 \frac{2 \mathcal{R} J \cdot \mathbf{h} \cdot \mathbf{F}_J \cdot \mathbf{h} \cdot \mathbf{F}_J \cdot \hat{x}}{2 \sqrt{2}} \hat{x}$$

and

$$F_{J}^{SN} = (-1)^J \mathcal{E} 2 \mathcal{R} J \cdot \mathbf{h} \cdot \mathbf{X}_q \cdot \mathbf{h} \cdot \mathbf{X}_q \cdot \hat{x}$$

$$T_{J}^{SN} = (-1)^J \mathcal{E} 2 \mathcal{R} J \cdot \mathbf{h} \cdot \mathbf{X}_q \cdot \mathbf{h} \cdot \mathbf{X}_q \cdot \hat{x}$$

where $\mathcal{R} = \frac{1}{2} |r_J|^2 + \frac{1}{2} A_J$ with $A_J$ the $J$-th mirror power absorption.
and contributions can be ignored. Formally they are reported in Appendix A (Eqs. (A1, A4)) while \( \tilde{T}_{J_q, cav} \) depends on the steady-state amplitudes of the cavity modes, represented by the vector \( \mathbf{v}_J \),

\[
\tilde{O}_{0,J} = \mathbf{v}_J^\dagger \cdot \tilde{O}_0 \cdot \mathbf{v}_J
\]

(26)

with \( \tilde{O}_{0,J} = \tilde{F}_{0,J} \cdot \tilde{T}_{0,J} \cdot \tilde{O} \). Matrices \( \tilde{F}_{0,J} \) and \( \tilde{T}_{0,J} \) and \( \tilde{O} \) have important consequences on the mechanical stability, as discussed by several authors for plane-parallel and concave mirrors \([10, 18]\).

Eventually, the shot-noise contributions (Eq. (21)) are expressed by

\[
\tilde{X}_{J_i}^{SN} = t_1^{-1} J_p v_J \cdot G_p \cdot X_i \cdot \delta \tilde{\alpha}_p^{SN} e^{i \phi t} + H.c.
\]

with \( i \in (\psi, \theta_y, \theta_z) \) and take in the frequency domain the form

\[
\tilde{X}_{J_i}^{SN} = t_1^{-1} J_p \Re \{ v_J \cdot G_p^\dagger \cdot X_i \cdot \delta \tilde{\alpha}_p^{SN} \}
\]

(27)

Finally, on the \( J \)'s mirror mode act the forces,

\[
\mathcal{F}_{J_s, rp}^{DEF} = (-1)^J \xi^2 2\Im \hbar k \cdot (\hat{x} + \hat{\bar{X}}_{J_s}^{DEF} + \delta \hat{\bar{X}}_{J_s, cav}^{DEF} \cdot \hat{x})
\]

\[
\mathcal{F}_{J_s, rp}^{DEF SN} = (-1)^J \xi 2\Im \hbar k \cdot \tilde{X}_{J_s}^{DEF SN} \cdot \hat{x}.
\]

(28)

**FIG. 2:** Axial \( F_\psi \), \( F_{1X_p} \), \( F_{1Y_p} \) and angular \( T_{1x} \), \( T_{1x, z} \), \( T_{1y} \), \( T_{1y, z} \) stiffness coefficients vs. length \( L \) of a symmetric cavity for angular misalignments \( \theta_y = 0.1 \), \( \theta_z = 1 \) mrad and detunings \( \psi = 1, 2, 3 \pi / F \). The round-trip phase factor \( e^{i \varphi t} \) has been ignored.

where

\[
\delta \hat{\bar{X}}_{J_s, cav}^{DEF} = e^{i \varphi t} \delta \hat{\bar{X}}_{J_s, cav}^{DEF} \cdot \mathbf{v}_J
\]

(29)

is the force acting on the \( J_s \)-mode due to the deformations of the mirror surfaces. In this case the force does not factorize as for the suspension modes, \( \hat{\bar{F}}_{J_s, cav}^{DEF} \) (Eq. (20)) represent the effects of the vibrations of the modes \( J_s \)'s on the \( J_s \) one.

Next, the shot-noise force is given by

\[
\hat{\bar{X}}_{J_s}^{DEF SN} = t_1^{-1} J_p \Re \{ v_J \cdot G_p^\dagger \cdot \delta \hat{\bar{X}}_{J_s}^{SN} \}
\]

(30)

In Fig. 2 the optically induced stiffness coefficients have been plotted for a set of detunings and angular misalignments, in an almost concentric cavity having a finesse \( F = 500 \) and output spot sizes of \( 2 \times 10^{-3} \) m. Being close to the concentric configuration also the stiffness coefficients \( F_{1X_p, y} \), \( T_{1x, y, z} \) become comparable with \( F_\psi \), \( T_{1x, y, z} \) for cavity axis misaligned by \( \theta_y = 10^{-2} \) rad, \( \theta_z = 10^{-1} \) rad. The signs of the stiffness coefficients may have important consequences on the mechanical stability, as discussed by several authors for plane-parallel and concave mirrors \([10, 15]\).
A. Small misalignment and mismatch

In the limit of small misalignment and mismatch the vector $\mathbf{v}_1$ (Eq. (25)) reduces to $\mathbf{v} = \{\delta v_y, \delta v_z, 0, \ldots, 0\}$ with

$$\delta v_q = -\frac{\sqrt{2}}{\omega_1} \frac{Q_y^* Q_q}{Q_y - Q_q} \left( \theta_q - \frac{\epsilon_q}{\ell_1} \right)$$

For mirror 2 $v_q$ is multiplied by $e^{-i\varphi_G}$. Splitting forces and torques in 0-th and 1-st order terms in these misalignment parameters $\delta F_j$ and $\delta T_{jq}$ of Eqs. (25) take the simpler forms,

$$\delta F_j = \delta F_j^{(0)} + \delta F_j^{(1)}$$
$$\delta T_{jq} = \delta T_{jq}^{(0)} + \delta T_{jq}^{(1)}$$

where

$$\delta F_j^{(0)} = F_{0j} \mu^\ell + \tilde{F}_v \delta \psi_{j, cav} + \delta F_{j, DEF}^{DP}$$
$$\delta F_j^{(1)} = \delta \tilde{F}_{jx} \delta \alpha''_{j, cav} + \delta \tilde{F}_{jy} \delta \alpha'_{j, cav}$$
$$\delta T_{jq}^{(0)} = \tilde{T}_x \delta \alpha''_{j, cav} + \tilde{T}_y \delta \alpha'_{j, cav}$$
$$\delta T_{jq}^{(1)} = \delta \tilde{T}_{jx} \delta \psi_{j, cav}$$

with

$$\delta \tilde{F}_{jx/y} = 2 \Re \left\{ \tilde{F}_{jx/y} v_j \right\}$$
$$\delta \tilde{T}_{jx/y} = 2 \Re \left\{ \tilde{T}_{jx/y} v_j \right\}$$

$\tilde{F}_{jx/y}$ and $\tilde{T}_{jx/y}$ being defined in Appendix C. Accordingly, in the ideal setting of the cavity the forces and torques are respectively proportional to longitudinal $\delta \psi_{j, cav}$ and transverse $\delta \alpha''_{j, cav}$ fluctuations through the stiffness coefficients $F_v, \tilde{T}_{jx/y}$. A slight deviation from it introduces forces and torques with a reverse dependence on fluctuations, say $\delta \tilde{F}_j^{(1)}, \delta \tilde{T}_{jx}$ depend respectively on $\delta \alpha_{j, cav}$ and $\delta \psi_{j, cav}$.

IV. ERROR SIGNALS

The errors used for controlling the cavity are provided by Drever-Pound (DP) and quadrant detector signals (QD). In the DP detection technique the photodetector current $I(t)$, obtained from the light transmitted and reflected by the input mirror, is mixed with a local oscillator $\sim \sin (k \Lambda t + \varphi)$ with positive odd integer k and low-pass filtered by an averaging procedure

$$s^{DP}_I(t) = \int_{-\infty}^{t} K^{DP}_{I} (t - t') \sin (k \Lambda t' + \varphi) I(t') \, dt'$$

with the filter response $K^{DP}_{I} (t - t')$ extended to a suitable interval much longer than $(k \Lambda)^{-1}$, and short compared to the time scale of the phase-quadrature fluctuations. Tuning $\varphi$ around 0 $s^{DP}_I$ can be maximized for a misaligned cavity.

![FIG. 3: Drever-Pound static characteristic $\bar{s}$ vs. $\psi$ for cavity length 1÷10 cm and $\varphi = 0$. The plots correspond to modulation frequency $\Lambda = 2e^\lambda / (\pi w^2)$, depth $M = 0.1$, and jaw angle $\delta \theta_1 = 0.01$.](image)

Putting $\delta a^{SN}_p = \delta a^{SN} (\varpi + p \Lambda)$, $s^{DP}$ is represented in the frequency domain by

$$s^{DP}/K^{DP}_{II} = e^2 (s^{DP} \mu^\ell + \tilde{s}^{DP}_{Q} \delta \alpha_{cav} + \delta \tilde{s}^{DP}_{DEF})$$

with

$$\delta s^{DP}_{DEF} = v_1 \cdot \left( \tilde{I}^{DP}_{+} - \tilde{I}^{DP}_{-} \right) \cdot v_1$$

$\delta s^{DP}_{DEF}$ defined in Appendix B.

In Figure 3 the static characteristic $\bar{s}^{DP}$ versus $\psi$ has been plotted for a set of cavity lengths and modulations.

Figure 4 contains plots of the coefficients $s_{x/y}$ vs. cavity length for $\varphi = 0$, $\theta z = 0.1$ mrad and 7 detunings. They show that as a consequence of the misalignment $s_{x/y}$ becomes comparable to $s_\varphi$, so that the D-P error signal contains contributions of the torsional fluctuations around the vertical axis.

At low frequency $\delta s^{DP}_{DEF}$ becomes proportional to the thermal noises $\delta \epsilon T_{TH}$.

The quadrant detector used for stabilizing the angular oscillations provides two error signals $s^{QD}_q (t)$ ($q = x, y$), proportional to expressions similar to (28) with the current $I$ replaced by $I_q = \beta \cdot Q_q \cdot \beta$ with

$$\beta = e^{-ipM} \alpha^{OUT}_p + \delta a^{OUT SN}_p$$

the matrix $Q_q$ representing the function $sgn (\bar{q})$. Then, $s^{QD}_q$ is given by an expression similar to (28) with $G^{OUT}_p$ replaced by $G^{OUT\dagger}_p \cdot Q_q$.

A. Small misalignment and mismatch

In the limit of small misalignment and mismatch the signal can be split into zeroth- and first-order contributions

$$\delta s^{DP} = \delta s^{(0)} + \delta s^{(1)}$$
tions around the axis $q \delta \theta$ closes the loop of the cavity-field system. Of geometry which in turn changes the stored field and fluctuations are transferred to the mirrors proportionally and mirror surface deformations. The radiation pressure $\sigma \delta x, \delta \epsilon$ A deviation from alignment introduces in the error signal given respectively by (Eqs. (C4))

\[
\begin{align*}
\bar{s}'(0)/\tilde{K}^{DP} &= \xi^2 \left( \bar{s}_\psi\bar{m}^\ell + \bar{s}_\psi\delta \tilde{\psi}_1,\text{cav} + \bar{s}^{(0)} D E F \right) + \xi \bar{X}^{SN}(0), \\
\delta \bar{s}'(1)/\tilde{K}^{DP} &= \xi^2 \left( \delta \bar{s}_X \delta \bar{a}^{(0)}_{1,\text{cav}} + \delta \bar{s}_Y \delta \bar{a}^{(0)}_{1,\text{cav}} + \tilde{\delta} \bar{s}^{(1)} D E F \right) + \xi \bar{X}^{SN}(1),
\end{align*}
\]

with $\delta \bar{s}_X/Y_q = 2 \text{Re} \{ \tilde{s}_X/Y_q \psi_{1q} \}$ and $\tilde{s}_X/Y$ defined in Appendix C.

For a perfectly aligned and matched cavity the D-P signal is sensitive to the axial fluctuations $\delta \tilde{\psi}_1,\text{cav}$, mirror deformation term $\delta \tilde{a}^{(0)} D E F$ and shot noise $\bar{X}^{SN}(0)$. In particular, a contribution $\delta \tilde{a}^{(0)}_{1,\text{cav}}$ depending on the mirror thermal noise $\delta \tilde{a}^{(0)}_{1,\text{cav}}$ is added to the length fluctuations. A deviation from alignment introduces in the error signal contributions proportional to the transverse fluctuations.

V. 3D MODEL

The deviations of each mirror from the reference position is described by the displacements $\delta x, \delta \epsilon_x$ and $\delta z, \delta \epsilon_z$ of its vertex and the angular parameters $\delta \theta_x = -\delta \Omega_y$ and $\delta \theta_y = \delta \Omega_x$. As said $\delta \Omega_q$ describes a right-handed rotations around the axis "q", so that $\delta \theta_z$ is a left-handed tilt and $\delta \theta_y$ a right-handed torsion. These quantities fluctuate as a consequence of suspension thermal fluctuations and mirror surface deformations. The radiation pressure fluctuations are transferred to the mirrors proportionally with the laser intensity. The cavity reacts by changes of geometry which in turn changes the stored field and closes the loop of the cavity-field system.

From a purely-mechanical point of view if the design is good (that is, symmetric enough) the suspension masses are aligned along the vertical axis $z$, perpendicular to the cavity axis $x$. In these conditions the torsion $\delta \theta_y$ and vertical $\delta \epsilon_x$ degrees of freedom are uncoupled. A coupling between longitudinal motion $\delta x$ and tilt $\delta \theta_z$ is generally speaking unavoidable. This is true also for the transverse displacement $\delta \epsilon_y$ which is coupled with the rotation around the optical axis. It goes without saying that in a real situation it is very difficult to avoid more general cross couplings.

Radiation pressure can increase or reduce existing couplings, and it can also produce new ones. While $\delta \epsilon_x$ is insensitive to radiation pressure, $\delta \theta_y$ responds to the radiation torque. For this reason when asymmetric optical modes are excited the rotations $\delta \theta_q$ modify the radiation pressure, and ultimately couple $\delta x$ and tilting, but also $\delta \theta_y$ and torsion.

Before proceeding further it is worth replacing the displacements $\delta \epsilon_{xq}$ by $\delta \psi_{1q} = 2\xi \delta \epsilon_{xq}$, the angles $\delta \theta_{1q}$ by $\delta \psi_{1q} = \sqrt{2} k^\ell \psi_{1q} \delta \theta_{1q}$ and introducing a new five component vector $\delta \psi_{1q} = (\delta \psi_{1q}, \delta \psi_{1q}, \delta \theta_{1q})$ which forms with the cavity mode amplitudes a system of correlated stochastic processes. It is usually a very good approximation to model the suspension as a set of damped, independent oscillators coupled to an heat bath. Each oscillator $J \lambda \tilde{\psi}$, labelled by $\lambda$, specifying the prevalent character of the mode (tilting, torsion, displacements, violin modes), and the mode index $\lambda$, can be parameterized with its effective mass $M_{\lambda \tilde{\psi}}$, pulsation $\omega_{\lambda \tilde{\psi}}$ and damping coefficient $\gamma_{\lambda \tilde{\psi}}$. For rotations $M_{\lambda \theta}$ is replaced by the moment of inertia. These parameters are related to the masses and stiffness constants of the system. The coordinates of the mirror can be written as linear combinations of the oscillator’s coordinates $\psi_n$, and this means that each normal mode gives in principle a contribution to the mirror’s motion. By interacting with thermal baths these modes undergo Brownian motions by influencing the electromagnetic field, eventually coupling mechanical and radiation pressure fluctuations.

A. Suspension Langevin system

By linearizing the equation of motion of each mirror ($J \lambda$) the horizontal ($x$ and $y$) and vertical ($z$) displacements $\delta \tilde{\psi}_{1q}$, torsion $\delta \tilde{\theta}_{1q}$, tilt $\delta \tilde{\theta}_{1q}$ and rotation around the cavity axis $\delta \tilde{\theta}_{1q}$ are expressed in terms of the amplitudes $\tilde{A}_{\lambda \tilde{\psi}}$ of the normal modes as

$$\delta \tilde{\psi}_{1q} = K_{J \mu \tilde{\psi}} \tilde{A}_{\lambda \tilde{\psi}}$$

having indicated by $J \mu$ a generic degree of freedom and by $K_{J \mu \tilde{\psi}}$ the coupling coefficient with the mode $J \lambda \tilde{\psi}$.

If the mirror vertex coincides with the center of mass of the suspension payload, and the centers of the suspended masses are aligned along the vertical $z$-axis, the suspension can be easily modeled by considering only the
couplings $\delta \psi_J - \delta \tilde{\theta}_J$ and $\delta \psi_{Jq} - \delta \tilde{\psi}_J$, and assuming the vertical oscillations independent of the other degrees of freedom. Being the amplitudes of the cavity modes independent of the rotations $\delta \tilde{\theta}_J$, the suspended cavity is described by the collection $\delta \psi_J$ of five fluctuating quantities, depending linearly on radiation pressure-torques, thermal noise, D-P and quadrant detector error signals, thermal noise, D-P and quadrant detector error signals, thermal noise, D-P and quadrant detector error signals, thermal noise, D-P and quadrant detector error signals, thermal noise, D-P and quadrant detector error signals, thermal noise, D-P and quadrant detector error signals, thermal noise, D-P and quadrant detector error signals.

In case the mirror vertex and/or the centers of the suspension wire clampings are displaced from the respective mass centers, the vertical fluctuations are coupled to the other ones.

The effect of the servo systems acting on the longitudinal and angular mirror displacements have been included by indicating by $H^{DP}$ and $H^{QD}$ the respective transfer functions.

For the mirror vibrations a Langevin equation for each mode must be considered since their profiles are different (Eq. (30)),

$$\delta \tilde{\nu} = \chi_{\nu} s_{\nu} \left( E^2 \delta E_{\nu} + E \tilde{X}_{\nu}^{SN} \right) + \chi_{\nu} s_{\nu} \left( E^2 \delta T_{\nu} + E \tilde{X}_{\nu}^{SN} \right)$$

$$\delta \tilde{\theta} = \chi_{\theta} s_{\theta} \left( E^2 \delta E_{\theta} + E \tilde{X}_{\theta}^{SN} \right) + \chi_{\theta} s_{\theta} \left( E^2 \delta T_{\theta} + E \tilde{X}_{\theta}^{SN} \right)$$

In writing Eq. (35) the interaction with the mirror noise was approximated with Eq. (11) while in Eq. (30) the effects of the suspension fluctuations were ignored. Loosely speaking the two systems refer respectively to the low and high frequency regions. In the former the suspensions are mutually coupled by radiative forces represented while the mirror vibrations generate a global thermal noise hiding the single mode contributions. In the latter the suspensions appear frozen and the mirror modes are mutually coupled by radiative forces represented by $\delta \tilde{F}_{j, cav}$.

The solutions of the homogeneous system (35) represent, in absence of feedback forces, free mechanical oscillations of the suspended cavity, stable or unstable in accordance with the sign of the imaginary part of the oscillation frequency.

For a more detailed analysis (35) and (36) should be mirrored by the system relative to the quantities $\delta \tilde{\nu}_{J}, \delta \tilde{\theta}_{J}$ conjugate of $\delta \psi_{J}, \{ \delta \psi_{Jq}, \delta \tilde{\psi}_{J} \}$, which can be obtained from the above one by replacing $\chi_{\nu}/\theta_{q}/\theta_{s}$ by $\chi_{\nu}/\theta_{q}/\theta_{s}$ and $X_{\nu}/\theta_{q}/\theta_{s}$ (Eq. (30) and $X_{\nu}/\theta_{q}/\theta_{s}$, $X_{\nu}/\theta_{q}/\theta_{s}$, $X_{\nu}/\theta_{q}/\theta_{s}$, $X_{\nu}/\theta_{q}/\theta_{s}$, $X_{\nu}/\theta_{q}/\theta_{s}$ (Eq. (11) in the random force expressions.

### B. Susceptibilities

The susceptibility $\chi_{J, \nu}$ describes the action on the coordinate $\nu$ of the force/torque acting on $\nu$,

$$\chi_{J, \nu} = K_{J, \nu} \chi_{J, \nu}$$

with $\chi_{J, \nu}$ the susceptibility of the mode $J, \nu$ of frequency $\omega_{J, \nu}$ and damping coefficient $\gamma_{J, \nu}$

$$\chi_{J, \nu} = \frac{\omega_{J, \nu}}{\omega_{J, \nu}^2 - \omega^2 - i \omega \gamma_{J, \nu}}$$

and $K_{J, \nu}, K_{J, \nu}$ the coupling coefficients with $\mu$ and $\nu$ mirror coordinates, while the adimensional Lamb-Dicke factor

$$\eta_{J, \nu} = \sqrt{\frac{\hbar}{2 M_{J, \nu} \omega_{J, \nu}}}$$

depends on the mode mass $M_{J, \nu} = M_{J, \nu} K_{J, \nu}$ (the subfix $i$ identifies the $i$-th mass of the suspension). For rotations $M_{J, \nu}$ is replaced by $J_{J, \nu}/\omega_{J, \nu}$ with $J_{J, \nu}$ the moment of inertia. Some authors use the so-called optomechanical coupling constants $G_{J, \nu} = 2 \sqrt{2 \eta_{J, \nu}^2 / \gamma_{J, \nu}}$ [21].

The mechanical susceptibility $\chi_{J, \nu}$ is similar to (37) while the mass appearing in the Lamb-Dicke factor varies for the different modes, as reported in [24].

### C. Thermal contributions

Assuming suspension masses at the same temperature $T$, each mode is characterized by a thermal source (see
Appendix D) 

\[
\dot{X}_{J\lambda j}^{TH} = \sqrt{\frac{4k_B T}{\hbar \omega_{J\lambda j}}} \xi_{J\lambda j} - i \frac{\omega}{\omega_{J\lambda j}} \sqrt{\frac{\hbar}{3k_B T}} \eta_{J\lambda j} \]  

(39) 

with \( \eta, \xi \) delta correlated random forces introduced by Diosi [12] in order to remove some inconsistencies of the classical Langevin equation.

A Y-version of (39) can be easily obtained for the Y-quadratures corresponding to the above ones by replacing \( \chi_{J\mu \lambda j} \) by

\[
\dot{Y}_{J\lambda j}^{TH} = \frac{4k_B T}{\hbar \omega_{J\lambda j}} \xi_{J\lambda j} - i \frac{\omega}{\omega_{J\lambda j}} \sqrt{\frac{\hbar}{3k_B T}} \eta_{J\lambda j} \]  

(41)

The terms proportional to \( \eta_{J\lambda j} \) in Eqs. (39) and (41) can be generally neglected except when the temperature is rather low and the oscillation frequencies very high, a situation met only in some mirror modes.

\( \eta_{J\lambda j} \) disappears in the simple Brownian motion model while in Ref. [14] \( \eta_{J\lambda j} \) has been dropped and \( \sqrt{\frac{4k_B T}{\hbar \omega_{J\lambda j}}} \xi_{J\lambda j} \) replaced by a new delta correlated random noise source \( \tilde{Q}_{J\lambda j} \).

The thermal sources \( \tilde{X}_{J\mu \lambda j}^{TH} \) are superpositions of the \( \tilde{X}_{J\lambda j}^{TH} \) weighted by the thermal susceptivities

\[
\dot{\tilde{X}}_{J\lambda j}^{TH} = \kappa_{J\lambda j} \tilde{X}_{J\lambda j}^{TH} \]  

(40)

with \( \kappa_{J\lambda j} = 2 \sqrt{\eta_{J\lambda j}/\hbar \omega_{J\lambda j}} \).

The terms of (35) contain contributions proportional to the fluctuating quantities \( \delta_{j}^{L \lambda j} \)...

\[
\delta_{j}^{L \lambda j} = \sqrt{\frac{4k_B T}{\hbar \omega_{J\lambda j}} \sqrt{2h k_{B} c_{P} \phi_{j} \xi}} \]  

(43)

with \( \phi \) the loss angle, \( \xi \) a delta correlated random force and \( c_{P} \) depending on the illumination profile

\[
P(\vec{r}) = P_{\lambda_{y}, \lambda_{z}} e^{-\frac{\vec{r}^2}{2\sigma^2}} u_{\lambda_{y}, \lambda_{z}}(\vec{r}) \]  

(44)

For \( P(\vec{r}) \) differing notably from the Gaussian one the deformed profile of the mirror \( \delta u^{DEF}_{G} \) can be expressed, neglecting the finite size of the mirrors, by a suitable combination of derivatives of the deformation \( \delta u^{DEF}_{G}(\vec{r}) \) relative to a Gaussian distribution

\[
\delta u^{DEF}_{G}(\vec{r}) = \sum_{\lambda_{y}, \lambda_{z}} P_{\lambda_{y}, \lambda_{z}} (-w)^{\lambda_{y} + \lambda_{z}} \frac{\partial^{\lambda_{y}}}{\partial y^{\lambda_{y}}} \frac{\partial^{\lambda_{z}}}{\partial z^{\lambda_{z}}} \delta u^{DEF}_{G}(\vec{r}) \]  

(46)

For a Gaussian illumination \( c_{P} \) takes the form

\[
c_{P} = \frac{1 - \sigma^2}{2\pi E w_{j}} \]  

(45)

with \( w_{j} \) the spot-size and \( E, \sigma \) the Young’s modulus and Poisson ratio respectively. For a generic illumination \( c_{P} \) can be expressed as \( c_{P} = f_{P} c_{G} \) with

\[
f_{P} = \sum_{\lambda'} (-1)^{\lambda'} P_{\lambda'} \frac{P_{\lambda} P_{\lambda'}}{P_{0}^2} f_{\lambda \lambda'} \]  

(46)

\( f_{\alpha \beta} \) being the \( \alpha \beta \) coefficient of the expansion of \( \delta u_{G}(\vec{r}) e^{-\frac{\vec{r}^2}{2\sigma^2}} \) in modes \( u_{\lambda_{y}, \lambda_{z}}(\vec{r}) \).

VI. THE SUSPENDED CAVITY AS A BIPARTITE SYSTEM

When the frequency is in proximity of two close resonances of the mirror 1 and 2 modes, the system behaves as a quantum mechanical bipartite system described by Gaussian continuous variables. These systems can form EPR states characterized by their covariance matrix \( \sigma \) which can be used for evaluating the entanglement of the state and its content of quantum information.

The difference between the e.m. fields used in quantum optics and the present mechanical system concerns the sources of the respective states. The e.m. fields are produced by the e.m. vacuum noise entering through the mirrors of a cavity containing a nonlinear crystal. In the present case thermal and shot noises act as sources. Accordingly, the covariance matrix \( \sigma \) can be split into thermal \( \sigma^{TH} \) and shot noise \( (8\epsilon)^{2} \sigma^{SN} \) contributions obtained by separating \( \delta_{j} \) into \( \delta_{j}^{SN} = 8\epsilon \delta_{j}^{SN} + \delta_{j}^{TH} \) satisfying the Langevin system \( [E] \).

\[
\begin{bmatrix}
\delta_{j}^{SN/TH} \\
\delta_{j}^{SN/TH}
\end{bmatrix}
= \frac{1}{D} \begin{bmatrix}
\hat{P}_{22} & -\hat{P}_{12} \\
-\hat{P}_{21} & \hat{P}_{11}
\end{bmatrix} \begin{bmatrix}
\chi_{11}^{X} \delta_{j}^{SN/TH} \\
\chi_{22}^{X} \delta_{j}^{SN/TH}
\end{bmatrix}
\]  

(46)

with \( \hat{P}_{jj'} \) factors representing the radiation pressure effects

\[
\hat{P}_{jj'} = 1 - 8e^{i\pi \epsilon} \epsilon^{2} \Theta_{j} \chi_{j} \tilde{F}_{jj'}^{DEF} \]  

and their product \( \hat{D} = \hat{P}_{11} \hat{P}_{22} - \hat{P}_{12} \hat{P}_{21} \). An analogous system holds for \( \delta_{j}^{SN} \) with \( \chi_{j} \) replaced by \( \chi_{j}^{Y} \).

The output field contains a component (Eqs. (18,22))

\[
\delta \tilde{a}_{OUT} \propto \left( e^{i\pi \epsilon} \tilde{Z}_{1} \delta_{1} + e^{i\pi \epsilon/2} \tilde{Z}_{2} \delta_{2} \right) \cdot \nu_{1}
\]  

(47)

proportional to \( \delta_{1,2} \) through the matrices \( \tilde{Z}_{j} = \tilde{G}_{j} \cdot \phi \cdot \epsilon \cdot \chi_{j} \cdot \tilde{G}^{*} \) and a shot noise \( \tilde{G}_{OUT} \cdot \delta \tilde{a}_{SN}^{1} + \epsilon^{2} \tilde{G} \cdot \delta \tilde{a}_{SN}^{2} \) term. Hence, depending \( \delta_{1,2} \) linearly on the quadratures \( \tilde{X}_{1,2}^{DEF} \) the output exhibits some degree of
squeezing, a feature exploited by several groups in the context of gravitational antennas of the next generation \[22\]. The dependence of the efficiency of the ponderomotive squeezing on the mirror deformation profiles (matrices \( \hat{Z}_j \)) and residual misalignment/mismatch can be easily analyzed by means of Eqs. \[10\] and the correlations of Apps. E and F.

The complex dynamics of cavity field and ponderomotive effects may lead to the creation of quantum entangled states of the two mirror modes, as shown by Mancini et al. \[21\] and references therein included). These authors have proposed a measure \( \mathcal{E}(\varpi) \) of the entanglement degree (the smaller \( \mathcal{E}(\varpi) < 1 \) the larger the entanglement) based on a combination of the elements of the covariance matrix,

\[
\mathcal{E}(\varpi) = \frac{\left| \delta \varsigma_1 + \delta \varsigma_2 \right|^2 \left| \delta \varsigma_1^T - \delta \varsigma_2^T \right|^2}{\left| \delta \varsigma_1, \delta \varsigma_2^T \right|^2} \tag{47}
\]

Splitting the quadratures into shot noise and thermal contributions, taking into account the many modes of the cavity and the shapes of the mirror mechanical modes, and scaling the ratio terms by keeping constant \( \mathcal{E}(\varpi) \), yield for the thermal and shot noise contributions

\[
\frac{\left| \delta \varsigma_1^{TH} + \delta \varsigma_2^{TH} \right|^2}{2} = \left| \chi_j^{TH} \right|^2 \tilde{C}_{j}^{TH} X^{(+)} \tag{48}
\]

\[
-\frac{1}{2} \frac{\left| \delta \varsigma_1^{SN} + \delta \varsigma_2^{SN} \right|^2}{\left| \omega_j \right|^2} = \left( \frac{\omega_j}{\omega_j} \right)^2 \left| \alpha_j \chi_j^{TH} \right|^2
\]

\[
\frac{\left| \delta \varsigma_1^{SN} - \delta \varsigma_2^{SN} \right|^2}{\left| \omega_j \right|^2} = \left| \chi_j \chi_j^* \tilde{C}_{j,j'}^{SN} X^{(+)} \right|
\]

\[
\left| \delta \varsigma_1^{SN} \hat{a}_{SN Y}^{+} \right|^2 = \left( \frac{\omega_j}{\omega_j} \right)^2 \frac{\chi_j}{\omega_j} \chi_j^* \tilde{C}_{j,j'}^{SN} Y^{(-)}
\]

where \( \chi_j^{TH} \) defined in \[22\], while \( \left| \delta \varsigma_1^{TH} - \delta \varsigma_2^{TH} \right|^2 \) and \( \left| \delta \varsigma_1^{SN} - \delta \varsigma_2^{SN} \right|^2 \) are similar to \[48\]–a and –c with \( \chi_j \), \( \tilde{C}_{j}^{TH} X^{(+)} \) and \( \tilde{C}_{j,j'}^{SN} X^{(+)} \) replaced respectively by \( \chi_j^* \), \( \tilde{C}_{j}^{TH} Y^{(-)} \) and \( \frac{\omega_j}{\omega_j} \chi_j^* \tilde{C}_{j,j'}^{SN} Y^{(-)} \). On the other hand,

\[
(\alpha_1, \alpha_2) = \left( \hat{P}_{22}, \hat{P}_{12} \right) \left| \hat{p}_{1}^{(+)} \hat{p}_{2}^{(+)} \hat{p}_{1}^{(-)} \hat{p}_{2}^{(-)} \right|^{-1/2}
\]

\[
\hat{P}_{j,j'} = \hat{P}_{j,j} \pm \hat{P}_{j,j'}
\]

\[
\tilde{C}_{j}^{TH} X/Y^{(\pm)} = \text{Re} \left\{ \tilde{C}_{j}^{X/XY} \right\}
\]

\[

with \( \tilde{C}_{j,j',j''}^{SN} \), given by Eq. \[12\]. In App. E thermal noise correlations for the Lindblad–Diosi and the Giovannetti–Vitali MEs are explicitly given.

\[\text{VII. CONCLUSIONS}\]

A suspended cavity illuminated by a laser beam has been described as the mechanical response \( \delta \psi_j \) of each mirror of a linear system to radiative, thermal and shot noise forces. These perturbations have been linked to the mechanical responses by means of susceptibility coefficients. The model includes the mirror vibrations described by a set of mode amplitudes \( \delta \varsigma \), together with their shapes \( \varsigma \).

The radiative pressure forces and torques have been linearized with respect to \( \delta \psi_j \) and \( \delta \varsigma \), by obtaining sets of stiffness coefficients for the suspension (\( \hat{g} \)) and for the mirror modes (\( F_{j,j',j''}^{DEF} \)). Accordingly the radiative forces have been expressed as products of susceptibility coefficients, laser intensity transmitted to the cavity (\( e^2 \)), stiffness coefficients, and mechanical mode amplitudes.

Splitting the quadratures into shot noise and thermal contributions, taking into account the many modes of the cavity and the shapes of the mirror mechanical modes, and scaling the ratio terms by keeping constant \( \mathcal{E}(\varpi) \), yield for the thermal and shot noise contributions

\[
\frac{\left| \delta \varsigma_1^{TH} + \delta \varsigma_2^{TH} \right|^2}{2} = \left| \chi_j^{TH} \right|^2 \tilde{C}_{j}^{TH} X^{(+)} \tag{48}
\]

\[
-\frac{1}{2} \frac{\left| \delta \varsigma_1^{SN} + \delta \varsigma_2^{SN} \right|^2}{\left| \omega_j \right|^2} = \left( \frac{\omega_j}{\omega_j} \right)^2 \left| \alpha_j \chi_j^{TH} \right|^2
\]

\[
\frac{\left| \delta \varsigma_1^{SN} - \delta \varsigma_2^{SN} \right|^2}{\left| \omega_j \right|^2} = \left| \chi_j \chi_j^* \tilde{C}_{j,j'}^{SN} X^{(+)} \right|
\]

\[
\left| \delta \varsigma_1^{SN} \hat{a}_{SN Y}^{+} \right|^2 = \left( \frac{\omega_j}{\omega_j} \right)^2 \frac{\chi_j}{\omega_j} \chi_j^* \tilde{C}_{j,j'}^{SN} Y^{(-)}
\]

where \( \chi_j^{TH} \) defined in \[22\], while \( \left| \delta \varsigma_1^{TH} - \delta \varsigma_2^{TH} \right|^2 \) and \( \left| \delta \varsigma_1^{SN} - \delta \varsigma_2^{SN} \right|^2 \) are similar to \[48\]–a and –c with \( \chi_j \), \( \tilde{C}_{j}^{TH} X^{(+)} \) and \( \tilde{C}_{j,j'}^{SN} X^{(+)} \) replaced respectively by \( \chi_j^* \), \( \tilde{C}_{j}^{TH} Y^{(-)} \) and \( \frac{\omega_j}{\omega_j} \chi_j^* \tilde{C}_{j,j'}^{SN} Y^{(-)} \). On the other hand,

\[
(\alpha_1, \alpha_2) = \left( \hat{P}_{22}, \hat{P}_{12} \right) \left| \hat{p}_{1}^{(+)} \hat{p}_{2}^{(+)} \hat{p}_{1}^{(-)} \hat{p}_{2}^{(-)} \right|^{-1/2}
\]

\[
\hat{P}_{j,j'} = \hat{P}_{j,j} \pm \hat{P}_{j,j'}
\]

\[
\tilde{C}_{j}^{TH} X/Y^{(\pm)} = \text{Re} \left\{ \tilde{C}_{j}^{X/XY} \right\}
\]

\[
\tilde{C}_{j,j'}^{SN} X^{(\pm)} = \text{Re} \left\{ \tilde{C}_{j,j'}^{SN} \right\}
\]

\[
\tilde{C}_{j,j'}^{SN} Y^{(\pm)} = \text{Im} \left\{ \tilde{C}_{j,j'}^{SN} \right\}
\]

with \( \tilde{C}_{j,j',j''}^{SN} \), given by Eq. \[12\]. In App. E thermal noise correlations for the Lindblad–Diosi and the Giovannetti–Vitali MEs are explicitly given.
APPENDIX A: FORCE, TORQUES AND STIFFNESS OPERATORS

\[
\begin{align*}
\mathbf{F}_0 &= J^2_p G_p^t \cdot G_p \\
\mathbf{T}_{0,q} &= J^2_p G_p^t \cdot X_q \cdot G_p
\end{align*}
\] (A1)

Next, the stiffness operators \( \mathbf{\tilde{s}}, \mathbf{\tilde{\omega}}_q \) are given by

\[
\begin{align*}
\mathbf{\tilde{s}} &= 2 J^2_p \mathcal{S} \left\{ \mathbf{\tilde{s}}_p \right\} \\
\mathbf{\tilde{\omega}}_q &= 2 J^2_p \mathcal{S} \left\{ \mathbf{\tilde{\omega}}_{ap} \right\}
\end{align*}
\] (A2)

with

\[
\begin{align*}
\mathbf{\tilde{s}}_p &= e^{-i \varphi} R_p G_p^t \cdot G_p \cdot \mathbf{\Phi} \cdot \mathbf{\tilde{s}} \\
\mathbf{\tilde{\omega}}_{ap} &= e^{-i \varphi} R_q G_p^t \cdot X_q \cdot G_p \cdot \mathbf{\Phi} \cdot \mathbf{\tilde{\omega}} 
\end{align*}
\] (A3)

while

\[
\begin{align*}
\delta \tilde{F}_{J, cav}^{DEF} &= 2 J^2_p \mathcal{S} \left\{ \delta \mathbf{F}_{J, cav}^{DEF} \right\} \\
\delta \mathbf{T}_{J, cav}^{DEF} &= 2 J^2_p \mathcal{S} \left\{ \delta \mathbf{T}_{J, cav}^{DEF} \right\}
\end{align*}
\] (A4)

where \( \delta \mathbf{z}_{J cav} \) takes the Levin’s form,

\[
\delta \mathbf{z}_{J cav} = e^{i \varphi} \mathbf{z}_{J cav} + e^{i \varphi/2} (\mathbf{z}_{J cav}^L)^2
\]

Finally, the action of the modes \( J, \omega \) on the Js one is represented by the ensemble of matrices

\[
\begin{align*}
\mathbf{\tilde{F}}_{J_s J_s'} &= 2 J^2_p \mathcal{S} \left\{ \mathbf{\tilde{F}}_{J_s J_s'}^{DEF} \right\}
\end{align*}
\] (A6)

with

\[
\begin{align*}
\mathbf{\tilde{F}}_{J_s J_s'}^{DEF} &= e^{-i \varphi} R_p G_p^t \cdot \mathbf{z}_{J_s} \cdot \mathbf{\tilde{G}}_p \cdot \mathbf{\Phi} \cdot \mathbf{z}_{J_s'} \cdot G_p
\end{align*}
\] (A7)

APPENDIX B: DREVER-POUND SIGNAL

\[
\begin{align*}
\mathcal{T}_{J}^{DP} &= 2 J_{p-k} J_p \mathcal{S} \left\{ e^{i \varphi} G_p^{OUT} \cdot G_p^{OUT} \right\} \\
\mathcal{T}_{J}^{DP} &= 2 J_{p+k} J_p \\
\mathcal{R} \left\{ e^{-i \psi} R_{p-k} G_p^{OUT} \cdot G_p^{OUT} \cdot \mathbf{\Phi} \cdot \mathbf{\tilde{\omega}} \cdot G_p^{OUT} \right\} \\
\delta \mathbf{I}_{J}^{DP}^{DEF} &= 2 J_{p+k} J_p \\
\mathcal{R} \left\{ e^{-i \psi} R_{p-k} G_p^{OUT} \cdot \mathbf{\tilde{G}}_p \cdot \mathbf{\Phi} \cdot \delta \mathbf{I}_{J}^{DEF} \cdot G_p^{OUT} \right\} \\
\mathcal{X}_{J}^{SN} &= 2 J_{p} \mathcal{S} \left\{ \mathcal{V} \cdot G_p^{OUT} \cdot \delta \mathbf{I}_{J}^{OUT} \cdot G_p^{OUT} \right\}
\end{align*}
\] (B1)

APPENDIX C: SMALL MISALIGNMENT AND MISMATCH

Assuming \( R = 1 \) and \( p = 0 \) the ponderomotive force and torques read

\[
\begin{align*}
\mathcal{F}_0 &= |G_{0(00,00)}|^2 \\
\mathcal{T}_{0, J} &= 2 \mathcal{R} \left\{ G_{0(00,00)}^* G_{0(10,10)} v_{J} \right\}
\end{align*}
\]

while the stiffness vectors reduce to

\[
\begin{align*}
\delta \mathbf{s}_J &= \delta \mathbf{s}_J^{(0)} + 2 \mathcal{R} \left\{ \delta \mathbf{s}_J^{(1)} \right\} \\
\delta \mathbf{\omega}_J &= \delta \mathbf{\omega}_J^{(0)} + 2 \mathcal{R} \left\{ \delta \mathbf{\omega}_J^{(1)} \right\}
\end{align*}
\] (C1)

with

\[
\begin{align*}
\delta \mathbf{s}_J^{(0)} &= \left( \tilde{F}_\psi, v_{J_0}, 0, 0, 0 \right) \\
\delta \mathbf{s}_J^{(1)} &= \left( 0, \tilde{T}_X, \tilde{T}_X, \tilde{T}_Y, \tilde{T}_Y \right) \\
\delta \mathbf{\omega}_J^{(0)} &= \left( 0, \tilde{F}_X v_{J_0}, \tilde{F}_X v_{J_1}, \tilde{F}_Y v_{J_0}, \tilde{F}_Y v_{J_1} \right) \\
\delta \mathbf{\omega}_J^{(1)} &= \left( 0, \tilde{T}_X (v_{J_0} + v_{J_1}), 0, 0, 0 \right)
\end{align*}
\] (C2)

where

\[
\begin{align*}
\tilde{F}_\psi &= 23 \left\{ e^{-i \varphi} e^{-i \varphi} G_{0(00,00)} |G_{0(00,00)}|^2 \right\} \\
\tilde{T}_X &= 23 \left\{ e^{-i \varphi} e^{-i \varphi} G_{0(10,10)} |G_{0(10,10)}|^2 \right\}
\end{align*}
\]

Similar expression holds for \( \tilde{F}_X \) and \( \tilde{T}_\psi \) with \( |G_{0(00,00)}|^2 \) replaced by \( G_{0(00,00)} G_{0(10,10)} \) while \( \tilde{F}_Y \) is similar to \( \tilde{F}_X \) with \( 3 \) replaced by \( \Re \).

Analogously, for the Drever-Pound error signal

\[
\begin{align*}
\mathcal{s}^{DP} &= \mathcal{s}^{(0)} \\
\mathcal{s}^{DP} &= \mathcal{s}^{(0)} + 2 \mathcal{R} \left\{ \mathcal{s}^{(1)} \right\} \\
\delta \mathbf{s}^{DP}^{DEF} &= \delta \mathbf{s}^{(0)}^{DEF} + 2 \mathcal{R} \left\{ \delta \mathbf{s}^{(1)}^{DEF} \right\}
\end{align*}
\] (C3)

with

\[
\begin{align*}
\mathcal{s}^{(0)} &= \left( \mathcal{s}_\psi, 0, 0, 0, 0 \right) \\
\mathcal{s}^{(1)} &= \left( 0, \mathcal{s}_X v_{1(00,00)}, \mathcal{s}_X v_{1(00,00)}, \mathcal{s}_Y v_{1(00,00)}, \mathcal{s}_Y v_{1(00,00)} \right) \\
\delta \mathbf{s}^{(0)}^{DEF} &= \mathbf{s}_\psi \left( e^{i \varphi} \mathcal{s}_1 \mathcal{s}_1 + e^{-i \varphi} \mathbf{z}_{1s} \right) \\
\delta \mathbf{s}^{(1)}^{DEF} &= \mathbf{s}_\psi \left( \mathcal{s}_1 \mathcal{s}_1 + e^{i \varphi} \mathbf{z}_{1s} \right) \\
&+ \mathbf{z}_2 \left( \mathcal{s}_1 \mathcal{s}_1 + e^{i \varphi} \mathbf{z}_{1s} \right) \\
&+ \mathbf{z}_2 \left( \mathcal{s}_1 \mathcal{s}_1 + e^{i \varphi} \mathbf{z}_{1s} \right)
\end{align*}
\]

where

\[
\begin{align*}
\mathbf{s}_\psi &= J_{p+k} J_p \left\{ e^{i \varphi} G_{p+k(00,00)}^* \right\} \\
\mathbf{s}_\psi &= J_{p+k} J_p \left\{ e^{-i \varphi} G_{p+k(00,00)}^* \right\} \\
\mathbf{s}_\psi &= J_{p+k} J_p \left\{ e^{i \varphi} G_{p+k(00,00)}^* \right\}
\end{align*}
\] (C5)
\( \hat{\delta}_X \) is similar to \( \hat{\delta}_Y \) with \( G^{OUT}_{p+k(00,00)} \), \( G^{OUT}_{p+k(11,11)} \) replaced by \( G^{OUT}_{p+k(10,10)} \), \( G^{OUT}_{p(10,10)} \), while \( \hat{\delta}_Y \) is similar to \( \hat{\delta}_X \) with \( \Re \) replaced by \( \Im \).

Finally the shot noise contribution reads
\[
\hat{X}^{DP SN} = \hat{X}^{DP SN}(0) + \hat{X}^{DP SN}(1)
\]
where
\[
\hat{X}^{DP SN}(0) = 2J_p \Re \left\{ G^{OUT}_{p(00,00)} \left( \delta a^\alpha_{p+k(00)} - \delta a^{\alpha}_{p-k(00)} \right) \right\}
\]
\[
\hat{X}^{DP SN}(1) = 2 \Re \left\{ G^{OUT}_{p+1(10,10)} \left( \left( \delta a^\alpha_{p+k(10)} - \delta a^{\beta}_{p-k(10)} \right) v_{1y}^* + \left( \delta a^\alpha_{p+k(01)} - \delta a^{\beta}_{p-k(01)} \right) v_{1z}^* \right) \right\}
\]

**APPENDIX D: THERMAL AND SHOT-NOISE SOURCES**

\[
\hat{X}^{TH/\Delta \phi} = \hat{\chi}_{\hat{X}^{TH/\Delta \phi}} + \hat{\chi}_{\hat{X}^{TH/\Delta \phi}} \hat{X}^{TH/\Delta \phi}
\]
\[
\hat{X}^{\Delta \phi} = \hat{\chi}_{\hat{X}^{\Delta \phi}} + \hat{\chi}_{\hat{X}^{\Delta \phi}} \hat{X}^{\Delta \phi}
\]
\[
\hat{X}^{TH/\Delta \phi} = \hat{\chi}_{\hat{X}^{TH/\Delta \phi}} + \hat{\chi}_{\hat{X}^{TH/\Delta \phi}} \hat{X}^{TH/\Delta \phi}
\]
\[
\hat{X}^{TH/\Delta \phi} = \hat{\chi}_{\hat{X}^{TH/\Delta \phi}} + \hat{\chi}_{\hat{X}^{TH/\Delta \phi}} \hat{X}^{TH/\Delta \phi}
\]
while for the mirror modes
\[
\hat{X}^{TEF SN}_{\Delta J_s} = \chi_{\hat{X}^{TEF SN}} \hat{X}^{TEF SN}_{\Delta J_s}
\]

**APPENDIX E: THERMAL NOISE CORRELATIONS**

The correlations \( C^{XX TH} (\varpi) C^{XX TH} (\varpi') \) of the thermal sources \( C^{XX TH} \) and \( C^{YY TH} \) for the Diosi master equation (see [7]) are given by

\[
\tilde{C}^{XX TH} = \frac{4k_BT}{\hbar\varpi_j} + \frac{2\varpi}{\varpi_j}
\]
\[
\tilde{C}^{YY TH} = \frac{4k_BT}{\hbar\varpi_j} + \frac{2\varpi_j}{\varpi^2} \hbar\varpi_j + \frac{2\varpi_j}{\varpi}
\]
\[
\tilde{C}^{XY TH} = \frac{4k_BT}{\hbar\varpi_j} + \frac{2\varpi_j}{\varpi^2} \hbar\varpi_j + \frac{2\varpi_j}{\varpi}
\]

while for the master equation of Ref. [14]
\[
\tilde{C}^{XX TH} = \tilde{C}^{YY TH} = \tilde{C}^{XY TH}
\]
\[
= \frac{2\varpi}{\varpi_j} \left( 1 + \coth \left( \frac{\hbar\varpi_j}{2k_BT} \right) \right)
\]

On the other hand the commutators coincide
\[
\left[ \hat{X}^{TEF SN}, \hat{Y}^{TEF SN} \right] = \frac{4\varpi}{\varpi_j} \quad (E2)
\]

**APPENDIX F: SHOT NOISE CORRELATIONS**

The Fourier transforms of the shot noise force and torque [27] are characterized by the correlations

\[
\tilde{C}^{SN}_{\Delta J_s \Delta J_s'} (\varpi) \tilde{C}^{SN}_{\Delta J_s' \Delta J_s} (\varpi') = \left( 1 + \frac{t^2}{t_1^2} \right) \tilde{C}^{SN}_{\Delta J_s \Delta J_s'} (\varpi) \tilde{C}^{SN}_{\Delta J_s' \Delta J_s} (\varpi')
\]

where

\[
\tilde{C}^{SN}_{\Delta J_s \Delta J_s'} = \chi_{\hat{X}^{SN}} \hat{X}^{SN}_{\Delta J_s} \cdot \hat{X}^{SN}_{\Delta J_s'}
\]

while

\[
\tilde{C}^{SN}_{\Delta J_s \Delta J_s'} = \chi_{\hat{X}^{SN}} \hat{X}^{SN}_{\Delta J_s} \cdot \hat{X}^{SN}_{\Delta J_s'}
\]

and \( i, i' = 1, 2, 3 \). In particular, \( \tilde{C}^{SN}_{\Delta J_s \Delta J_s'} = \tilde{C}^{SN}_{\Delta J_s \Delta J_s'} \).

Analogously for \( X_s^{TEF SN} \) (see [28]),

\[
\tilde{C}^{TEF SN}_{\Delta J_s \Delta J_s'} (\varpi) \tilde{C}^{TEF SN}_{\Delta J_s' \Delta J_s} (\varpi') = \left( 1 + \frac{t^2}{t_1^2} \right) \tilde{C}^{TEF SN}_{\Delta J_s \Delta J_s'} (\varpi) \tilde{C}^{TEF SN}_{\Delta J_s' \Delta J_s} (\varpi')
\]

where

\[
\tilde{C}^{TEF SN}_{\Delta J_s \Delta J_s'} = \chi_{\hat{X}^{TEF SN}} \hat{X}^{TEF SN}_{\Delta J_s} \cdot \hat{X}^{TEF SN}_{\Delta J_s'}
\]

and

\[
\tilde{C}^{TEF SN}_{\Delta J_s \Delta J_s'} = \chi_{\hat{X}^{TEF SN}} \hat{X}^{TEF SN}_{\Delta J_s} \cdot \hat{X}^{TEF SN}_{\Delta J_s'}
\]

with

\[
\tilde{C}^{TEF SN}_{\Delta J_s \Delta J_s'} = \tilde{C}^{TEF SN}_{\Delta J_s \Delta J_s'}
\]

In addition,

\[
\tilde{C}^{TEF SN}_{\Delta J_s \Delta J_s'} (\varpi) \tilde{C}^{TEF SN}_{\Delta J_s' \Delta J_s} (\varpi') = \frac{1}{2} \left( 1 + \frac{t^2}{t_1^2} \right) \Im \left\{ \tilde{C}^{TEF SN}_{\Delta J_s \Delta J_s'} \right\} \delta (\varpi + \varpi')
\]
