A model of the composite structure of quarks and leptons with $SU(4)$ gauge symmetry

N.G. Marchuk

Abstract

A model in which quarks and leptons consist of three "more elementary" particles of spin 1/2 is proposed. A gauge field theory with $SU(4)$ symmetry that corresponds to this model predicts the existence of two new bosons.

1. Introduction. During the last two decades the so-called Standard Model (SM) has a stable success in the description of elementary particle physics. The following particles are considered in the SM as elementary particles: quarks with three colors (red, yellow, blue) and six flavors - $u, d, c, s, t, b$; leptons - $e^-, \nu_e, \mu^-, \nu_\mu, \tau^-, \nu_\tau$; quanta of electroweak interactions - photon $\gamma$ and $W^\pm, Z^0$ bosons; Higgs particle $H$; quanta of strong interactions - gluons $g$ and antiparticles to all listed particles. Quarks and leptons are called fundamental fermions (FF), and quanta of electroweak and strong interactions are called fundamental bosons (FB). FF can be divided into three generations $(\nu_e u e^-, \nu_\mu c \mu^-, \nu_\tau t \tau^-)$, $(\nu_\mu s \mu^-, \nu_\tau b \tau^-)$.

Respective particles in different generations have similar properties but different masses that grow from first to third generation (masses of all types of neutrino possibly equal to zero). On that basis one can suppose an existence of the entire structure of quarks and leptons.

From the beginning of the seventies several models have been created that consider quarks and leptons as composite particles consisting of "more elementary" particles - preons, subquarks, maons, alphans, quinks, rishons, quips, haplons and so on. Almost all of those models can be included into one of the two classes - trio-fermion models in which quarks and leptons consist of three preons with spin 1/2 [1-13] and fermion-boson models in which quarks and leptons consist of one preon with spin 1/2 and one preon with spin 0 [14-18] (in the list of references only those articles are mentioned which were accessible to the present author). Among trio-fermion models, from our point of view, a most natural one is TCA-model of Terazawa, Chikashige and Akama [7] that collect several features from predecessors' models of Senju [2,3] and Pati, Salam and Strathdee [6,14]. Also, TCA-model is universal enough. As was mentioned by Terazawa [8], almost all models that were suggested before or after TCA-model can be considered as special cases of TCA-model. In particular this is true for the model [1] that was proposed as an attempt to improve Harari-Shupe model [9-12]. The universality of TCA-model has it adverse side - apart of 24 FF and 12 FB of SM TCA-model predicts the existence of more than 200 new fermions and bosons. That number is, probably, too big for the model that pretends to be realistic. So, if one wants to develop a realistic preon model, then one has to include in it some additional conditions that restrict a number of predicted new particles. An interesting attempt in this direction was made by Senju [4,5], who suggests that three preons in the particle have new preonic charge $1, 1, -2$ (he discussed the possibility to use a magnetic charge). In his resulting model a number of new particles is less than in TCA-model.

In the model [1] a postulate was formulated that a particle which consists of three preons cannot contain two preons with the same sign of electric charge. A further development of this postulate leads us to the present model in which there are no new fermions and only two new bosons $X,Y$ (boson $X$ with three colors).

A description of the model. Let us assume the existence of nine elementary particles with spin 1/2 $\alpha, \beta^r, \beta^u, \beta^b, \epsilon^u, \epsilon^d, \delta^1, \delta^2, \delta^3$.
Following [1], we shall call them inds†. Superscripts $r, y, b$ indicate colors of inds $\beta^r, \beta^y, \beta^b$; superscripts $u, d$ show the properties upness and downness of inds $\epsilon^u, \epsilon^d$ that associate with $u, d$ quarks and with neutrino and electron; superscripts 1, 2, 3 of inds $\delta^1, \delta^2, \delta^3$ indicate a generation of a particle. The quantum numbers of inds are collected in the table 1.

Table 1.

| Ind | Color | $B$ | $L$ | $Q$ | $Y^w$ | $I^w$ | $I^w$ | Mass |
|-----|-------|-----|-----|-----|-------|-------|-------|------|
| $\alpha$ | 0 | 0 | 1 | $-1/2 - Q'$ | $-1 - 2Q'$ | 0 | 0 | 0 |
| $\beta$ | $r, y, b$ | 1/3 | 0 | $1/6 - Q'$ | $1/3 - 2Q'$ | 0 | 0 | 0 |
| $\epsilon^u_L$ | 0 | 0 | 0 | $1/2 + Q'$ | $2Q'$ | $1/2$ | $1/2$ | 0 |
| $\epsilon^u_R$ | 0 | 0 | 0 | $1/2 + Q'$ | $1 + 2Q'$ | 0 | 0 | 0 |
| $\epsilon^d_L$ | 0 | 0 | 0 | $-1/2 + Q'$ | $2Q'$ | $1/2$ | $-1/2$ | 0 |
| $\epsilon^d_R$ | 0 | 0 | 0 | $-1/2 + Q'$ | $-1 + 2Q'$ | 0 | 0 | 0 |
| $\delta^1$ | 0 | 0 | 0 | 0 | 0 | 0 | 0 | $m_1$ |
| $\delta^2$ | 0 | 0 | 0 | 0 | 0 | 0 | 0 | $m_2$ |
| $\delta^3$ | 0 | 0 | 0 | 0 | 0 | 0 | 0 | $m_3$ |

Here $B$ - barion number; $L$ - lepton number; $Q$ - electric charge in units of proton charge; $Y^w$ - weak hypercharge; $I^w$ - weak isospin; $I^w_3$ - third component of weak isospin. The quantum numbers $Q, Y^w, I^w$ connected with each other by the Gell-Mann - Nishijima formula $Q = I^w_3 + Y^w/2$. Subscripts $L, R$ indicate that we consider left-handed and right-handed particles. The electric charge and the weak hypercharge of inds depend on unknown value of electric charge $Q'$ which we will discuss later.

Each FF of the SM (18 quarks and 6 leptons) we identify with a trio of inds as shown in the table 2 for the first generation particles.

Table 2.

| FF | Inds | Color | $B$ | $L$ | $Q$ | $Y^w$ | $I^w$ | $I^w_3$ |
|----|------|-------|-----|-----|-----|-------|-------|--------|
| $\nu_{eL}$ | $\alpha_L \epsilon^u_L \delta^1_R$ | 0 | 0 | 1 | 0 | $-1$ | $1/2$ | $1/2$ |
| $\nu_{eR}$ | $\alpha_R \epsilon^u_R \delta^1_L$ | 0 | 0 | 1 | 0 | 0 | 0 | 0 |
| $\epsilon^u_L$ | $\alpha_L \epsilon^u_L \delta^1_R$ | 0 | 0 | 1 | $-1$ | $-1$ | $1/2$ | $-1/2$ |
| $\epsilon^u_R$ | $\alpha_R \epsilon^u_R \delta^1_L$ | 0 | 0 | 1 | $-1$ | $-2$ | 0 | 0 |
| $u_L$ | $\beta_L \epsilon^d_L \delta^1_R$ | $r, y, b$ | 1/3 | 0 | 2/3 | 1/3 | $1/2$ | $1/2$ |
| $u_R$ | $\beta_R \epsilon^d_R \delta^1_L$ | $r, y, b$ | 1/3 | 0 | 2/3 | 4/3 | 0 | 0 |
| $d_L$ | $\beta_L \epsilon^d_L \delta^1_R$ | $r, y, b$ | 1/3 | 0 | $-1/3$ | 1/3 | $1/2$ | $-1/2$ |
| $d_R$ | $\beta_R \epsilon^d_R \delta^1_L$ | $r, y, b$ | 1/3 | 0 | $-1/3$ | $-2/3$ | 0 | 0 |

We get tables for FF of second and third generations by replacing ind $\delta^1$ with $\delta^2$ and $\delta^3$ respectively. As we see from the tables 1 and 2, the quantum numbers of quarks and leptons are the precise sums of quantum numbers of inds that constitute FF. The electric charges and the weak hypercharges of FF do not depend on $Q'$. So the value $Q'$ is called a hidden electric charge. We do not consider it as a free parameter of the model supposing that $Q'$ has a definite value that satisfies a condition $|Q'| > 1/2$. But now we don’t know how to calculate or measure it.

From the nine types of inds one can construct 165 trios of inds. A question arise – is it possible to point out a selection rule which distinguishes 24 trios of inds that we identify with FF from the set of 165 trios? The answer is yes. For this purpose we have to consider the signs of electric charge of inds in trios. There are 10 variants: $(++, +, +, 0), (+, +, +, 0), (+, +, 0, 0), (+, 0, 0, 0), (0, 0, 0, 0), (0, 0, 0, 0), (0, 0, 0, 0), (0, 0, 0, 0), (0, 0, 0, 0), (0, 0, 0, 0)$. If we assume that $|Q'| > 1/2$ and consider trios of inds (2) with only one set of signs of electric charge $(0, -)$, then we see that there are precisely 24 such trios namely $\epsilon \omega \delta$ (6 pieces) and $\epsilon \beta \delta$ (18 pieces), and they correspond to quarks and leptons in table 2.

I have to admit that I cannot understand why this selection rule works. But it does work!

† Ind is a river taking it source in Himalayas. First draft of the model was done in 1993 in Bangalore during monsoon season.
Postulate 1. Let us assume that $|Q'| > 1/2$. From the nine inds (2) fermions can be formed as trios of inds in such a way that a fermion must contain two inds with nonzero electric charge with opposite signs of charge and one electrically neutral ind. Charged inds have the same handedness and a neutral ind has opposite handedness (hence, a general spin of trio is equal to $1/2$).

The postulate 1 we complete with postulate 2' about the structure of bosons. Later we’ll replace postulate 2' by a better one.

Postulate 2'. Let $|Q'| > 1/2$. From the nine inds (2) bosons can be formed as pairs ind-antiind (or superpositions of such pairs). Ind and antiind that constitute boson both have nonzero electric charge. Signs of electric charge of these ind and antiind are opposite and handedness is the same.

Let us consider bosons that consist of pairs ind-antiind. It is easy to check, that the following set of pairs exhaust all set of pairs that satisfy postulate 2':

$$\alpha\bar{\alpha}, \beta\bar{\beta}', \epsilon^c\epsilon^u, \epsilon^d\epsilon^d, \epsilon^d\epsilon^u, \alpha\bar{\beta}, \bar{\alpha}\beta$$

where indices $c, c'$ denote colors $r, y, b$.

Let us identify $W^\pm$ bosons with pairs from (3) $W^+ = \epsilon^u\epsilon^d$, $W^- = \epsilon^u\epsilon^d$; Gluons $g_1, \ldots, g_8$ identify with six pairs $\beta\beta', c \neq c'$ and with two superpositions of states: $\frac{1}{\sqrt{2}}(\beta r\bar{\beta}' r - \beta y\bar{\beta}' y), \frac{1}{\sqrt{6}}(\beta r\bar{\beta}' r + \beta y\bar{\beta}' y + 2\beta b\bar{\beta}' b)$. Let us denote by $\beta\bar{\beta}$ color singlet state $\beta\bar{\beta} = \frac{1}{\sqrt{2}}(\beta r\bar{\beta}' r + \beta y\bar{\beta}' y + \beta b\bar{\beta}' b)$ and identify photon $\gamma$ and $Z$ boson with the following superpositions of states:

$$\gamma = \phi_1\alpha\bar{\alpha} + \phi_2\epsilon^u\epsilon^d + \phi_3\epsilon^d\epsilon^d + \phi_4\beta\bar{\beta}, \quad (\phi_1^2 + \phi_2^2 + \phi_3^2 + \phi_4^2 = 1),$$

$$Z^0 = \theta_1\alpha\bar{\alpha} + \theta_2\epsilon^u\epsilon^d + \theta_3\epsilon^d\epsilon^d + \theta_4\beta\bar{\beta}, \quad (\theta_1^2 + \theta_2^2 + \theta_3^2 + \theta_4^2 = 1).$$

So, from the set (3) only pairs $\alpha\bar{\beta}', \bar{\alpha}\beta$ (c = r, y, b) cannot be identified with the FB of SM. Denote

$$X^c = \bar{\alpha}\beta', \quad c = r, y, b.$$  

Boson $X$ possesses colors $r, y, b$, electric charge $+2/3$, barion number $B = 1/3$, lepton number $L = -1$. Let’s call it a lepto-quark boson. The consideration of a scheme of gauge field theory, that will be done in sections 4,5, gives us a possibility to predict the existence of one new neutral boson

$$Y = \frac{1}{2}(\beta\bar{\beta} - \sqrt{3}\alpha\bar{\alpha}).$$

Bosons $X, Y$ have spin 1 and are not yet discovered experimentally. So we may suggest that their masses are larger then masses of $W^\pm, Z^0$ bosons. Let us assume the following interactions with the participation of $X$ boson:

$$u + \bar{v}_c \leftrightarrow X, \quad d + e^+ \leftrightarrow X,$$

$$c + \bar{v}_\mu \leftrightarrow X, \quad s + \mu^+ \leftrightarrow X,$$

$$t + \bar{v}_\tau \leftrightarrow X, \quad b + \tau^+ \leftrightarrow X.$$

$$g^{c'c} + X^c \leftrightarrow X^c, \quad (c, c' = r, y, b),$$

$$\gamma + X \leftrightarrow X,$$

$$Z^0 + X \leftrightarrow X.$$

The properties of $Y$ boson are similar to the properties of $Z^0$ boson - all the FF have nonzero probabilities to emit or absorb boson $Y$.

Strong and electroweak interactions of particles with the participation of FB and interactions of particles with the participation of $X, Y$ bosons can be interpreted as an exchange of constituent parts (inds) of interacting particles. FB and $X, Y$ are particles that accomplish such an exchange (there is an evident

\[\| G.'t \text{ Hooft} [19] \text{ argues that cannot exist particles with spin 3/2 which consist of three massless fermions.}\]
analogy with the exchange of quarks between nucleons with the aid of pions). For example, let us consider several reactions and their interpretations on ind level

\[
\begin{align*}
  u^r + g^{\tilde{y}} & \leftrightarrow u^y & \equiv \beta^r \epsilon^u \delta^1 + \tilde{\beta}^r \beta^y \leftrightarrow \beta^y \epsilon^u \delta^1 \\
  g^r b + g^b y & \leftrightarrow g^r y & \equiv \beta^r \tilde{\beta}^b + \beta^b \tilde{\beta}^y \leftrightarrow \beta^y \tilde{\beta}^b \\
  e^- + \nu_e & \leftrightarrow W^- & \equiv \alpha \epsilon^d \delta^3 + \tilde{\alpha} \epsilon^u \delta^1 \leftrightarrow \epsilon^d \epsilon^u \\
  d + \bar{u} & \leftrightarrow W^- & \equiv \beta^d \delta^1 + \tilde{\beta}^u \delta^1 \leftrightarrow \epsilon^d \epsilon^u \\
  u + \nu_e & \leftrightarrow X & \equiv \beta^u \delta^1 \leftrightarrow \beta^y \bar{\alpha} \\
  d + e^+ & \leftrightarrow X & \equiv \beta^d \delta^1 \leftrightarrow \tilde{\beta}^y \bar{\alpha} \\
  g^r y + X^y & \leftrightarrow X^r & \equiv \beta^r \tilde{\beta}^y \leftrightarrow \beta^r \bar{\alpha}
\end{align*}
\]

In all reactions barion and lepton numbers are conserved. Hence, a decay of proton is impossible.

Note. Although the interpretation of FB as pairs ind-antiind (or superpositions of pairs) does not reflect peculiarity of weak interactions that is connected with the definite handedness of interacting particles, but it gives us the obvious explanation to all known interactions of particles and predicts some new interactions. Also, as we shall see in a moment, this interpretation predetermines the lagrangian which describes a dynamics of interacting particles. When a lagrangian will be written, FB may be considered as the corresponding gauge fields.

**Aquacolor.** There is an evident analogy between present model, which consider quarks and leptons as trios of inds, and quantum chromodynamics which consider barions as trios of quarks. It leads to the assumption that all inds have one more quantum number with three possible values, which we shall call aquacolor. Antiinds have antiaquacolor. Suppose, that quarks and leptons are aquacolor singlets (states antisymmetric in aquacolor). Suppose also an existence of aquacolor gluons - aquagluons, which are quanta of an aquacolor interaction that confines trios of inds in quarks and leptons with the dimension, probably, less then $10^{-17}cm$. It seems natural to describe aquacolor interaction as a gauge field theory with $SU(3)$ symmetry that corresponds to aquacolor and with the lagrangian (lagrangian density)

\[
\tilde{\psi}(i\gamma_\mu D_\mu - m)\psi - \frac{1}{4} F_{\mu\nu}^l F^{l}_{\mu\nu}
\]

where $\psi$ - 12 component spinor wave function of ind,

\[
D_\mu = \partial_\mu - iaA_\mu, \quad A_\mu = A_\mu^l \frac{\lambda_l}{2}, \quad l = 1, \ldots, 8
\]

\[
F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu - ia[A_\mu A_\nu - A_\nu A_\mu] = F_{\mu\nu}^l \frac{\lambda_l}{2}
\]

$\lambda_l$ - Gell-Mann’s matrices, $\gamma_\mu$ - Dirac’s matrices, $m$ is not zero only for $\delta^1, \delta^2, \delta^3$.

The lagrangian (3) differs from the QCD lagrangian by the coupling constant $a$, which must guarantee a confinement radius less than $10^{-17}cm$. The lagrangian has to describe interactions of inds due to exchange of aquagluons on the distances that are less or comparable with the confinement radius. For the description of interactions of particles due to exchange of inds on the distances greater than the confinement radius we have to use another lagrangian.

**Strong and electroweak interactions.** For a description of dynamics of strong and electroweak interactions on the ind level at the distances of order $10^{-16} - 10^{-13}cm$ without taking into account interactions
with $X, Y$ bosons, we suggest to use the lagrangian that is immediately written using rules of SM

$$\Psi i\gamma_\mu (\partial_\mu - \frac{1}{3} - 2Q') \frac{ig_1}{2} B_\mu - \frac{ig_3}{2} \lambda' C_\mu^I) \Psi$$

$$+ \Phi i\gamma_\mu (\partial_\mu - (-1 - 2Q') \frac{ig_1}{2} B_\mu) \Phi$$

$$+ \bar{L}_i \gamma_\mu (\partial_\mu - (2Q') \frac{ig_1}{2} B_\mu - \frac{ig_2}{2} \tau^k W^k_\mu) L$$

$$+ R^u i\gamma_\mu (\partial_\mu - (1 + 2Q') \frac{ig_1}{2} B_\mu) R^u$$

$$+ R^d i\gamma_\mu (\partial_\mu - (-1 + 2Q') \frac{ig_1}{2} B_\mu) R^d$$

$$+ \sum_{k=1}^{3} \bar{\Omega}_k (i\gamma_\mu \partial_\mu - m_k) \Omega_k$$

$$- \frac{1}{4} B_{\mu\nu} B^{\mu\nu} - \frac{1}{4} W^k_{\mu\nu} W^{k\mu\nu} - \frac{1}{4} C_{\mu\nu} C^{\mu\nu}$$

$$+ |D_\mu \phi|^2 - \frac{1}{2} \lambda^2 (|\phi|^2 - \frac{1}{2} \eta)^2$$

where we have sum over $\mu, \nu = 0, 1, 2, 3$; $k = 1, 2, 3$; $l = 1, \ldots, 8$. $\phi = \left( \begin{array}{c} \phi^+ \\ \phi_0 \end{array} \right)$ – complex dublet of scalar fields with $Y^w = 1$ and the covariant derivative has the form

$$D_\mu = \partial_\mu - \frac{ig_1}{2} B_\mu - \frac{ig_2}{2} \tau^k W^k_\mu;$$

$\lambda, \eta$ – real constants. After the gauge transformation the dublet $\phi$ has a form

$$\phi = \frac{1}{\sqrt{2}} \left( \begin{array}{c} \eta \\ \chi(x) \end{array} \right),$$

where constant $\eta$ is a vacuum average and $\chi$ – real scalar field. $\Psi, \Phi, L, R^u, R^d, \Omega_k$ – spinor wave functions of the following multiplets of inds:

$$\Psi = \left( \begin{array}{c} \beta^r \\ \beta^b \end{array} \right), \Phi = \left( \begin{array}{c} \alpha \\ L \end{array} \right), R^u = \left( \begin{array}{c} \epsilon^u_k \\ \epsilon_u^l \end{array} \right), R^d = \left( \begin{array}{c} \epsilon^d_k \\ \epsilon_d^l \end{array} \right), \Omega_k = \left( \delta^k \right), k = 1, 2, 3.$$

$\bar{\Psi}, \bar{\Phi}, \bar{L}, \bar{R}^u, \bar{R}^d, \bar{\Omega}_k$ – spinorial conjugated wave functions. $g_1, g_2$ – electroweak coupling constants (sometimes they are denoted by $g', g$). $g_3$ – strong coupling constant

$$B_{\mu\nu} = \partial_\mu B_\nu - \partial_\nu B_\mu,$$

$$W_{\mu\nu} = \partial_\mu W_\nu - \partial_\nu W_\mu - ig_2 [W_\mu, W_\nu] = W_{\mu\nu}^k - \frac{1}{2} \frac{\tau^k}{2}, \quad W_\mu = W^k_\mu \frac{\tau^k}{2}$$

$$C_{\mu\nu} = \partial_\mu C_\nu - \partial_\nu C_\mu - ig_3 [C_\mu, C_\nu] = C_{\mu\nu}^\pm \frac{\lambda^l}{2}, \quad C_\mu = C_{\mu}^l \frac{\lambda^l}{2}$$

Values $\lambda'^l_\mu$ define vector fields of gluons. Vector field $A_\mu$ of photon $\gamma$ and vector fields $Z^0_\mu, W^\pm_\mu$ of $Z^0, W^\pm$ bosons calculated as

$$A_\mu = \frac{1}{\sqrt{g_1^2 + g_2^2}} (g_2 B_\mu + g_1 W^3_\mu)$$

$$Z^0_\mu = \frac{1}{\sqrt{g_1^2 + g_2^2}} (-g_1 B_\mu + g_2 W^3_\mu)$$

$$W^\pm_\mu = \frac{1}{\sqrt{2}} (W^1_\mu \mp iW^2_\mu)$$
A term $|D_\mu \phi|^2$ gives mass terms for the intermediate bosons (indices $\mu$ not written)

$$\frac{\eta^2}{8} (g_2 W^3 - g_1 B)^2 + \frac{\eta^2 g_2^2}{2} W^- W^+$$

and masses

$$m_Z = \frac{\eta\sqrt{g_1^2 + g_2^2}}{2}, \quad m_W = \frac{\eta g_2}{2}, \quad \frac{m_W}{m_Z} = \cos \theta_W.$$

Usual formulas connect constants $g_1, g_2$ with the electromagnetic coupling constant $\epsilon$ and Weinberg angle $\theta_W$

$$\epsilon = \frac{g_1 g_2}{\sqrt{g_1^2 + g_2^2}} = g_2 \sin \theta_W, \quad \tan \theta_W = \frac{g_1}{g_2}.$$

A mass of scalar field $\chi$ (Higgs particle $H$) has a form $m_H = \lambda \eta$. Connection between vacuum average $\eta$ and Fermi constant $G$ is given by formula $\eta = (\sqrt{2}G)^{-1/2}$.

So, the lagrangian (5) describes interactions between spinor fields of ind $\alpha, \beta, \epsilon$ and gauge vector fields $B_\mu, C_\mu, W_\mu^\pm$ which define vector massless fields $A_\mu, C_\mu$. Fields $A_\mu, C_\mu$ can be identified with the physical fields of photon and gluons. In order to identify fields $Z^0_\mu, W^\pm_\mu$ with the physical fields of $Z^0, W^\pm$ bosons we have to use a mass generation mechanism for $Z^0, W^\pm$ bosons.

In physics there are two well known mass generation mechanisms for $Z^0, W^\pm$ bosons that can be included to the present model. The first is Higgs mechanism that is based on doublet of complex scalar fields $(\phi^+, \phi^0)$, which (together with antidoublet) have been "eaten" by $Z^0_\mu, W^\pm_\mu$ fields with the creation of massive $Z^0, W^\pm$ bosons and a scalar Higgs particle. This mechanism is accepted in the SM. An existence of fundamental scalars in the theory creates some difficulties (a mass hierarchy problem [20]), which stimulate development of models with composite scalar particles. Such models are called technicolor models [21-24]. In those models the existence is assumed of new particles – techniquarks and technigluons which constitute a composite particles with a confinement radius of order $10^{-17}$ cm. In the second mass generation mechanism from $Z, W$ become massive "eating" goldstone technipions, which appear after spontaneous breaking of chiral symmetry in quantum technichromodynamics. As was shown by Weinberg [21], both mass generation mechanisms lead to the same empirically successful identity $m_W/m_Z = \cos \theta_W$. The evident possibility to identify techniquarks with ind and technicolor with aquacolor shows that second mass generation mechanism for $W^\pm, Z^0$ is rather attractive for the use in present model.

5. Inclusion of $X, Y$ bosons. In order to describe interactions with the participation of $X, Y$ bosons let us join inds $\beta$ and $\alpha$ in one multiplet. Now $\Psi$ is a column vector which consists of wave functions of ind $\beta^r, \beta^b, \beta^b, \alpha$. In that case first two terms in (5) must be replaced by

$$\Psi i \gamma_\mu (\partial_\mu - (-2Q') \frac{ig_\mu}{2} B_\mu - \frac{ig_3}{2} \xi^l C^l_\mu) \Psi + |D'_\mu \phi_2|^2 - \frac{1}{2} \lambda_2 \xi^2 (|\phi_2|^2 - \frac{1}{2} \eta_2^2)^2, \quad (6)$$

where $\lambda_2, \eta_2$ – real constants, $\phi_2$ – quartet of complex scalar fields with zero weak hypercharge $Y^w = 0$.

$$\phi_2 = \begin{pmatrix} \phi_1 \\ \phi_2 \\ \phi_3 \\ \phi_4 \end{pmatrix}, \quad D'_\mu = \partial_\mu - \frac{ig_3}{2} \xi^l C^l_\mu.$$
\[ \xi^{11} = \begin{pmatrix} \vdots & \cdots & 1 \\ \vdots & \vdots & \vdots \\ 1 & \cdots & \cdots \end{pmatrix}, \quad \xi^{12} = \begin{pmatrix} \vdots & \cdots & -i \\ \vdots & \vdots & \vdots \\ i & \cdots & \cdots \end{pmatrix}, \]

\[ \xi^{13} = \begin{pmatrix} \vdots & \cdots & 1 \\ \vdots & \cdots & 1 \\ 1 & \cdots & \vdots \end{pmatrix}, \quad \xi^{14} = \begin{pmatrix} \vdots & \cdots & -i \\ \vdots & \cdots & i \\ i & \cdots & \vdots \end{pmatrix}, \quad \xi^{15} = \frac{1}{\sqrt{6}} \begin{pmatrix} 1 & 1 & \cdots \\ \cdots & \cdots & \cdots \\ \cdots & \cdots & 1 \end{pmatrix}, \]

where points stand on the places of zeros. Bosons that correspond to fields \( C_{\mu}^1, \ldots, C_{\mu}^8 \) can be identified with gluons of QCD, and fields \( C_{\mu}^9, \ldots, C_{\mu}^{15} \) – with vector bosons \( X, \bar{X}, Y \).

\[
\begin{align*}
X^r_{\mu} &= \frac{1}{\sqrt{2}} \left( C_{\mu}^9 - i C_{\mu}^{10} \right), \\
\bar{X}^r_{\mu} &= \frac{1}{\sqrt{2}} \left( C_{\mu}^9 + i C_{\mu}^{10} \right), \\
X^y_{\mu} &= \frac{1}{\sqrt{2}} \left( C_{\mu}^{11} - i C_{\mu}^{12} \right), \\
\bar{X}^y_{\mu} &= \frac{1}{\sqrt{2}} \left( C_{\mu}^{11} + i C_{\mu}^{12} \right), \\
X^b_{\mu} &= \frac{1}{\sqrt{2}} \left( C_{\mu}^{13} - i C_{\mu}^{14} \right), \\
\bar{X}^b_{\mu} &= \frac{1}{\sqrt{2}} \left( C_{\mu}^{13} + i C_{\mu}^{14} \right), \\
Y_{\mu} &= C_{\mu}^{15}.
\end{align*}
\]

The inclusion of a quartet of scalar fields \( \phi_5 \) with nonzero vacuum average \( \eta_5 \) spontaneously breaks \( SU(4) \) symmetry of the resulting lagrangian to color \( SU(3) \) symmetry. With the aid of gauge \( SU(4) \) transformation the quartet \( \phi_5 \) transforms into

\[
\phi_5 = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ 0 \\ 0 \\ \eta_5 + \chi_5(x) \end{pmatrix},
\]

where \( \chi_5 \) – real scalar field. From a term \( |D_{\mu}^r \phi_5|^2 \) we get the mass terms for \( X,Y \) bosons

\[
\frac{\eta_5^2 g_3^2}{4} \left( 2 X^r \bar{X}^r + 2 X^y \bar{X}^y + 2 X^b \bar{X}^b + \frac{3}{2} Y^2 \right)
\]

that give the following masses:

\[
m_X = \frac{g_3 \eta_5}{2}, \quad m_Y = \frac{g_3 \eta_5}{2} \sqrt{\frac{3}{2}}, \quad \frac{m_X}{m_Y} = \sqrt{\frac{2}{3}}.
\]

Gluons remain massless. A mass of scalar field \( \chi_5 \) (new Higgs particle \( H_5 \)) has a form \( m_{H_5} = \lambda_5 \eta_5 \).

In that scheme of gauge field theory with \( U(1) \times SU(2) \times SU(4) \) symmetry one can see the following analogy: photon \( \gamma \) corresponds to gluons \( g_1, \ldots, g_8 \); \( W^\pm \) bosons correspond to \( X, \bar{X} \) bosons; \( Z^0 \) boson corresponds to \( Y \) boson.

Now we can formulate postulate 2 which may replace postulate 2’ from section 2.

**Postulate 2.** Bosons of the present model identify with a gauge fields of lagrangian (5) with (6).

So, postulates 1,2 give us a model of elementary particles with \( SU(4) \) gauge symmetry which contains all known FF and FB of SM and predicts two new bosons \( X,Y \).

### 6. Questions.

The lagrangian (5),(6) describes the interactions of particles on a level of inds. In the description of interactions of particles on the level of composite FF two very important questions arise:

- How to reflect a mixing of \( d,s,b \) quarks states (a Cabibbo angle)?
- What is a mass generation mechanism for FF?

There are other important questions:

- Why the selection rule formulated in the section 2 works?
- What is a value of hidden electric charge $Q'$?
- Is the present model renormalizable?
- In what experiments $X, Y$ bosons may be discovered?

We thank A.A.Komar for fruitful discussions.
