Quantization of Solitons in Coset Space

J.Manjavidze\textsuperscript{a}), A.Sissakian\textsuperscript{b})

October 23, 2018

Abstract

The perturbation theory around the soliton fields of the sin-Gordon model is developed in the coset space. It is shown by explicit calculations that all corrections to the topological soliton contribution are canceled exactly.

I. Introduction

The problem of quantization of the extended objects was formulated mainly in the middle of 70-th, see the review paper \(^1\) and references cited therein. One starts from the classical Lagrange equation:

\[
\frac{\delta S(u)}{\delta u(x, t)} = 0, \tag{1}
\]

where, for simplicity, \(u(x, t)\) is the real scalar field \(^2\). If this equation has nontrivial solution \(u_c(x, t)\) then the problem of its quantization will arise. One of the first attempts to construct the perturbation theory was based on the WKB expansion in vicinity of \(u_c\) \(^3\).

The Born-Oppenheimer method was adopted also \(^4,5\). First of all, to construct the quantum mechanics the structure of Hilbert space \(\mathcal{H}\) is postulated. So, it is assumed that the Fock column consist from the vacuum state \(|0\rangle\) and from the multiple meson states \(|p_1, p_2, ..., p_n\rangle\), \(n \geq 1\). The ordinary perturbation theory operates just with this 'meson' sector only. The anzats \(|P_1, P_2, ..., P_l\rangle\) for the \(l\)-soliton state, \(l \geq 1\), is introduce also.

It is postulated that the quantum excitations in the soliton sector are described by the excitation of the 'meson' field \(^4\). Therefore, to construct the perturbation theory, there should also be the mixed states:

\[|P_1, ..., P_l; p_1, ..., p_n\rangle, \quad l \geq 1, \quad n \geq 1, \tag{2}\]

but, at the same time,

\[< P_1, ..., P_l; p_1, ..., p_n|p_1, ..., p_n' \rangle \equiv 0, \quad l \geq 1, \quad n + n' \geq 0, \tag{3}\]

i.e. it is assumed that the solitons are the absolutely stable field configurations \(^1\).

Present paper in definite sense completes the offered in \(^4,5\) picture. The (1+1)-dimensional exactly integrable sin-Gordon model will be considered to illustrate our result. We will investigate the multiple production of 'mesons' by 'soliton' and the truth of (3) will be shown at the end of explicit calculations. In other words, it will be shown that the offered in \(^4,5\) postulate concerning orthogonality of the 'meson' \(\mathcal{H}_m\) and 'soliton' \(\mathcal{H}_s\) Hilbert spaces can be proved. We will see that this conclusion follows from exactness of the semiclassical approximation for sin-Gordon model.
It should be noted that the exactness of semiclassical approximation in topological soliton sector of the sin-Gordon model is not ‘beyond the realm’ \(^6\). It is well known also that the integrable Coulomb problem is exactly semiclassical. The same we have for the quantum rigid rotator \(^7\), which is the isomorphic to Poshle-Teller model. The general discussion of the exactness of semiclassical approximation from a geometrical point of view was given in \(^8\).

It will be crucial for us in many respects to follow the WKB ideology. So, we will consider the ‘meson’ production amplitudes

\[
a_{nm}(p, q) = \langle p_1, \ldots, p_n | q_1, \ldots, q_m \rangle, \quad n, m = 1, 2, \ldots
\]

The index \(s\) means that the calculations are performed in the ‘soliton’ sector and \(p_i\) and \(q_i\) are the ‘meson’ momenta. By definition,

\[
p_i^2 = q_i^2 = m^2
\]

since the quantum uncertainty principle leads to the impossibility of mass-shell observation of the field \(^9\). The ordinary reduction formalism will be used to calculate \(a_{nm}\). This means that we will construct the \textit{phenomenological} \(S\)-matrix of the ‘meson’ interaction through the ‘soliton’ fields, i.e. we will start from the assumption that the states \((2)\) exist, and it will be shown at the end of calculations that such \(S\)-matrix is trivial:

\[
a_{nm}(p, q) \equiv 0, \quad n + m > 0.
\]

Offered in the paper formalism allows to prove \((3)\). For this purpose we will build the perturbation theory expansion over \(1/g\), where \(g\) is the interaction constant \(^{10}\). This perturbation theory is dual to the theory described in \(^1\), over \(g\), i.e. one can not decompose the definite order over \(g\) contribution in terms of the \(1/g\) expansion, and vice versa. So, only the summary results of both expansion may be compared.

Following to WKB ideology, to find the corrections to the semiclassical approximation in the vicinity of the extremum \(u_c(x, t)\), one should find the solution of the equation for the Green function:

\[
(\partial^2 + v''(u_c))G(x, t; x', t') = \delta(x - x')\delta(t - t'),
\]

where \(v''(u)\) is the second derivative of the potential function \(v(u)\). This Green function describes propagation of a particle in the time dependent
inhomogeneous and anisotropic external field \( u_c(x, t) \). Generally, this problem has not a closed solution. So, for instance, the attempt to solve the problem using the momentum decomposition \(^{11}\) leads to the hardly handling double-parametric perturbation theory. To avoid this problem we will build new perturbation theory over \( 1/g \).

Imagining particles coordinates as the elements of the Lee group, the classical particles motion may be described mapping the trajectory on group manifold. Roughly speaking, this means that the group combination law creates the particles classical trajectory \(^{12}\).

Moreover, this program was realized for description of the particle quantum motion \(^{13}\). It was shown for essentially nonlinear Lagrangian \( L = \frac{1}{2}g_{\mu\nu}(x)\dot{x}^\mu\dot{x}^\nu \) that the semiclassical approximation is exact on the (semi)simple Lee group manifold. But this slender solution of quantum problems is destructed in presence of the interaction potential \( v(x) = O(x^n), n > 2 \), since last one breaks the isotropy and homogeneity of the Lee group manifolds \(^{10}\). The developed perturbation theory will describe the quantum perturbations breaking isotropy and homogeneity of the group manifold.

Developed formalism contains the following steps \(^{10,14}\). (i) We will introduce the manifold \( W_G \) of trajectories \( u_c \), solving the eq.(I). The manifold \( W_G \) will be labeled by the local coordinates \((\xi, \eta)\), i.e. we will consider \( u_c = u_c(x; \xi, \eta) \) since \( u_c \) should belong to \( W_G \) completely. (ii) The numbers \((\xi, \eta)\) are interpreted as the generalized coordinates of the ‘particle’. Then \( u_c(x; \xi, \eta) \) will define the external potential for it. The quantum motion of the ‘particle’ may be described noting that \( W_G \) is the homogeneous and isotropic manifold, since this case is rather quantum mechanical problem in the ‘flat’ space.

It was shown in \(^{14}\) that the WKB model \(^3\), where the field excitations in vicinity of \( u_c \) are decomposed over the ‘meson’ states, and our model quantum mechanics of the ‘particle’ in the external potential defined by \( u_c \), are isomorphic. In other words, we know that the quantum trajectory of the ‘particle’ covers the phase space \((\xi, \eta) \in W_G\) densely. But it should be noted also that described in \(^3\) model presents the expansion over the interaction constant \( g \) and our perturbation theory describes expansion over the \((1/g)\).

In the classical limit (labeled by the index ‘0’) the motion of our ‘par-
particle’ must be free\(^1\), i.e. its velocity should be a constant,

\[
\dot{\xi}_0 = \text{const}, \dot{\eta}_0 = 0. \tag{7}
\]

This may be achieved expressing the set \(\{\eta\}\) through the set of generators of the subgroup broken by \(u_c\)^\(^1\). It is evident, such choice of the ‘particles’ coordinate gives the same effect as in the above discussed transformation to the homogeneous and isotropic (semi)simple Lee group manifold\(^1\), see also\(^1\). Moreover, we will see that even in the case of nontrivial potential function, one can get to the free ‘particles’ motion, rescaling the quantum sources\(^1\).\(^4\).

Thus, the necessary invariant subspace \(W_G\) would be chosen equal to the coset space \(G/G_c\):

\[
W_G = G/G_c, \tag{8}
\]

where \(G\) is the symmetry group and \(G_c \subset G\) is the classical solutions \(u_c\) symmetry group. The problem of quantization of the coset space have a reach history, see e.g.\(^1\). Described in\(^1\),\(^4\) formalism presents one of possible realization of the coset spaces quantization scheme.

The last one means that we will realize the transformation generated by the classical trajectory\(^4\):

\[
u_c : (u, p)(x, t) \rightarrow (\xi, \eta)(t) \tag{9}
\]

Such construction of perturbation theory in the \(W_G\) space require the additional effort noting that the dimension of the original phase space \((u, p) \in T^*V\) is infinite. Therefore, \((9)\) assumes the infinite reduction since the dimension of coset space \(W_G\) is finite\(^1\). The crucial for us reduction scheme was formulated in\(^4\).

In other words, quantizing the sin-Gordon soliton fields, the space coordinate would be an irrelevant variable. This is the well known fact, e.g.\(^3\), and it leads to the Lorentz non-covariant perturbation theory. It is the consequence of absolute stability of the solitary waves profile, i.e. of conservation of the topological charge. The necessary information concerning this question will be given in Sec.3.

Having the complete theory, one can analyze the perturbations. The crucial point of the new perturbation theory is the statement\(^1\) that the quantum corrections are accumulated strictly on the boundaries \(\partial W_G\)
(bifurcation manifolds $^{19,20,15}$) of the $W_G$ space. Therefore, if
\[ \partial u_c \cap \partial W_G = \emptyset, \] (10)
then the problem is exactly semiclassical. On other hand, (10) means conservation of the topological charge: $\partial u_c$ is the flow induced by the quantum perturbations in $W_G$ and if (10) is not satisfied, then a flow into the forbidden domain with other topological charge, separated by the bifurcation boundary, should exist. So, (10) is the topological charge conservation law.

Notice, the solution (10) leads to (6) since particles production is the pure quantum effect. This will be shown in Sec.4.

The paper is organized as follows. In Sec.2 we will (i) formulate the necessary for us boundary conditions to derive the LSZ reduction formulae, (ii) find the explicit expression for $a_{nm}$, (iii) formulate the mapping into the coset space $W_G$. In Sec.3 we will (i) consider the sin-Gordon model, (ii) discuss necessary in the coset space boundary condition, (iii) remind the structure of the new perturbation theory $^{14}$, (iv) describe ‘meson’ multiple production to show (6).

II. Density matrix on the Dirac measure

Main point of this section is the attempt to generalize the ordinary for field theory boundary condition:
\[ u(x \in \sigma_\infty) = 0, \]
where $\sigma_\infty$ is the remote hypersurface. This boundary condition is used to remove the surface term, and it is necessary to formulate the reduction formalism. We would like introduce the new boundary condition to have a possibility to include the non-vanishing on $\sigma_\infty$ field configurations and, at the same time, throw off the surface term.

The $(n + m)$-point Green functions $G_{nm}$ are introduced through the generating functional $Z_j$ $^{21}$:
\[ G_{nm}(x, y) = (-i)^{n+m} \prod_{k=1}^{n} \hat{j}(x_k) \prod_{k=1}^{m} \hat{j}(y_k)Z_j, \] (11)
where $\hat{j}(x) = \delta/\delta j(x)$ and the generating functional
\[ Z_j = \int Du e^{iS_j(u)}. \] (12)
The action

$$S_j(u) = S(u) - V(u) + \int dx dt j(x,t) u(x,t),$$  \hspace{1cm} (13)

where

$$S(u) = \int dx dt \left( \frac{1}{2} (\partial u)^2 - m^2 u^2 \right), \quad m^2 \geq 0,$$  \hspace{1cm} (14)

is the free part and $V(u)$ describes the interactions. At the end of calculations one should put $j = 0$.

To provide convergence, the integral (12) will be defined on the Mills complex time contour $C_+$. For example,

$$C_\pm : t \rightarrow t + i\varepsilon, \varepsilon \rightarrow +0, \quad -\infty \leq t \leq +\infty$$  \hspace{1cm} (15)

and after all calculations, one should return the time contour on the real axis putting $\varepsilon = 0$.

In a ‘meson’ sector the integration in (12) is performed over all field configurations with standard vacuum boundary condition:

$$\int d^2 x \partial_\mu (u \partial^\mu u) = \int_{\sigma_\infty} d\sigma_\mu u \partial^\mu u = 0.$$  \hspace{1cm} (16)

It follows from these conditions that

$$u(x \in \sigma_\infty) = 0, \quad p\alpha_\mu u(x \in \sigma_\infty) = 0.$$  \hspace{1cm} (17)

It excludes a contribution from the surface term since assumes that field disappeared on the remote hypersurface $\sigma_\infty$. Considering the ‘soliton’ sector this boundary condition require the modification since there is in the $(x - t)$ space such direction along which the soliton field does not disappeared. The integral (12) would have a formal meaning till this boundary condition will not be specified.

Let us introduce now the field $\varphi$ through the equation:

$$-\frac{\delta S(\varphi)}{\delta \varphi(x,t)} = j(x,t).$$  \hspace{1cm} (18)

It is assumed that we can formulate such boundary condition that the surface term may be neglected calculating the variational derivative in (18). Then we perform the ordinary shift $u \rightarrow u + \varphi$ in integral (12). Considering $\varphi$ as the probe field created by the source:

$$\varphi(x) = \int d^2 x' G_0(x - x') j(x'), \quad (\partial^2 + m^2) G_0(x - x') = \delta(x - x'),$$  \hspace{1cm} (19)
the connected Green function $G_{nm}^c$ only will be interesting for us:

$$G_{nm}^c(x, y) = (-i)^{n+m} \prod_{k=1}^{n} \hat{j}(x_k) \prod_{k=1}^{m} \hat{j}(y_k) Z(\varphi),$$

(20)

where

$$Z(\varphi) = \int D\varphi e^{iS(u) - iV(u + \varphi)}$$

(21)

is the new generating functional.

To calculate the nontrivial elements of $S$-matrix we must put the external particles on the mass shell. Formally this procedure means amputation of the external legs of $G_{nm}^c$ and further multiplication on the free particles wave functions. In result the amplitude of $n$- into $m$-particles transition $a_{nm}$ in the momentum representation has the form:

$$a_{nm}(q, p) = (-i)^{n+m} \prod_{k=1}^{n} \hat{\varphi}(q_k) \prod_{k=1}^{m} \hat{\varphi}^*(p_k) Z(\varphi).$$

(22)

Here the particles creation operator:

$$\hat{\varphi}^*(q) = \int d^2x e^{iqx} \hat{\varphi}(x), \quad \hat{\varphi}(x) = \frac{\delta}{\delta \hat{\varphi}(x)}.$$

(23)

was introduced. The eq.(22) is the ordinary LSZ reduction formulae. But one should remember that the boundary condition (16) should be generalized to have a permission for inclusion of the soliton contributions calculating $Z(\varphi)$.

Describing particles multiple production it is enough to consider the generating functional:

$$\rho(\alpha, z) = \exp\{- \int d\Omega_1(p) \left( \hat{\varphi}_+^*(p) \hat{\varphi}_-(p) e^{i\alpha_p z_+(p)} + \hat{\varphi}_-^*(p) \hat{\varphi}_+(p) e^{i\alpha_p z_-(p)} \right) \} Z(\varphi_+) Z^*(\varphi_-),$$

(24)

where

$$d\Omega_n(p) = \prod_{k=1}^{n} \frac{d^1p_k}{(2\pi)^22\epsilon(p_k)} = \prod_{k=1}^{n} d\Omega_1(p_k), \quad \epsilon(p) = (p^2 + m^2)^{1/2}.$$

Let us calculate

$$\int \frac{d^2\alpha_+}{(2\pi)^2} e^{-i\alpha_+} \frac{d^2\alpha_-}{(2\pi)^2} e^{-i\alpha_-} \prod_{k=1}^{n} \frac{\delta}{\delta z_+(p_k)} \prod_{k=1}^{m} \frac{\delta}{\delta z_-(q_k)} \rho(\alpha, z) \bigg|_{z_+ = z_- = 0}$$

8
Inserting here the definition (24), one can find that this expression gives:

\[ \delta(P - \sum_{k=1}^{n} p_k)\delta(P - \sum_{k=1}^{m} q_k)|a_{nm}(p, q)|^2, \]

where the \( \delta \)-functions are the result of integration over \( \alpha_{\pm} \). So, the factors \( e^{i\alpha_{\pm} p} \) in (24) permit to introduce the energy-momentum shell and the \( \delta \)-functions defines the restriction on the shell. The both restrictions

\[ P = \sum_{k=1}^{m} q_k, \quad P = \sum_{k=1}^{n} p_k \]

are compatible since the amplitude \( a_{nm} \) is translationally invariant. The integration over \( P \) gives energy-momentum conservation law.

Notice now that \( \rho(\alpha, z) \) is defined through the generating functional

\[
\rho_0(\varphi) = Z(\varphi_+)Z^*(-\varphi_-) = \int D\mu_+ D\mu_- e^{iS_+(u_+)-iS_-(u_-)} e^{-iV_+(u_+\varphi_+)+iV_-(u_-\varphi_-)}.
\]

Then, we can consider the ‘closed-path’ boundary condition:

\[ \int_{\sigma_{\infty}} d\sigma_\mu u_+ \partial_\mu u_+ = \int_{\sigma_{\infty}} d\sigma_\mu u_- \partial_\mu u_-, \]

instead of (16,17). The natural solution of this boundary condition is:

\[ u_+(x \in \sigma_{\infty}) = u_-(x \in \sigma_{\infty}) = u(x \in \sigma_{\infty}). \]

It provides cancelation of the surface term on the remote hypersurface \( \sigma_{\infty} \) independently on the ‘value’ of the field \( u(x \in \sigma_{\infty}) \).

Considering the system with the large number of particles, we can simplify calculations choosing the CM frame \( P = (P_0 = E, \vec{0}) \). It is useful also\(^{23}\) to rotate the contours of integration over

\[ \alpha_{0,k} : \quad \alpha_{0,k} = -i\beta_k, \text{Im}\beta_k = 0, k = 1, 2. \]

Then \( \rho(\beta, z) \) have a meaning of the density matrix, where \( \beta \) would have, in the some definite case\(^{24}\), meaning of the inverse temperature and \( z \) is the activity\(^{25}\).

It was shown in\(^{14}\) that the unitarity condition unambiguously determines contributions in the path integrals for \( \rho \). Exist the statement:
S1. The density matrix $\rho(\alpha, z)$ has following representation:

$$\rho(\alpha, z) = e^{-i\hat{K}(je)} \int DM(u) e^{iS_O(u) - iU(u,e)} e^{N(\alpha,z;u)} \equiv O(u) e^{N(\alpha,z;u)}.$$  \hspace{1cm} (28)

It should be underlined that this representation is strict and is valid for arbitrary Lagrange theory of arbitrary dimensions. The derivation of (28) is given in Appendix A.

Expansion over the operator:

$$\hat{K}(je) = \frac{1}{2} \text{Re} \int_{C_+} dx dt \frac{\delta}{\delta j(x, t)} \frac{\delta}{\delta e(x, t)} = \frac{1}{2} \text{Re} \int_{C_+} dx dt \hat{j}(x, t)\hat{e}(x, t)$$  \hspace{1cm} (29)

generates the perturbation series. We will assume that this series exist (at least in Borel sense). The variational derivatives in (29) are defined as follows:

$$\frac{\delta \phi(x, t \in C_i)}{\delta \phi(x', t' \in C_j)} = \delta_{ij} \delta(x - x')\delta(t - t')$$,  \hspace{1cm} i, j = +, -

where $C_i$ is the Mills time contour. The auxiliary variables $(j, e)$ must be taken equal to zero at the very end of calculations.

The functionals $U(u, e)$ and $S_O(u)$ are defined by the equalities:

$$S_O(u) = (S(u + e) - S(u - e)) + 2\text{Re} \int_{C_+} dx dt e(x, t)(\partial^2 + m^2)u(x, t),$$  \hspace{1cm} (30)

$$U(u, e) = V(u + e) - V(u - e) - 2\text{Re} \int_{C_+} dx dt e(x, t)v'(u),$$  \hspace{1cm} (31)

where $S(u)$ is the free part of the Lagrangian and $V(u)$ describes interactions. The phase $S_O(u)$ is not equal to zero if $u$ have the nontrivial topological charge $^{14}$. We will discusses carefully this question later.

The measure $DM(u, p)$ has the form:

$$DM(u) = \prod_{x,t} du(x, t) \delta \left( \frac{\delta(S(u) - V(u))}{\delta u(x, t)} + j(x, t) \right).$$ \hspace{1cm} (32)

The functional $\delta$-function in the measure means that the necessary and sufficient set of contributions in the integral over $u(x, t)$ is defined by the classical equation:

$$- \frac{\delta(S(u) - V(u))}{\delta u(x, t)} = j(x, t),$$ \hspace{1cm} (33)
‘disturbed’ by the quantum source $j(x, t)$

For further calculation another representation will be useful. If we insert into the integral (28)

$$1 = \int \prod_{x,t} dp(x, t) \delta(p(x, t) - \dot{u}(x, t))$$

then the measure $DM$ takes the form:

$$DM(u, p) = \prod_{x,t} du(x, t) dp(x, t) \times$$

$$\times \delta \left( \dot{u}(x, t) - \frac{\delta H_j(u, p)}{\delta p(x, t)} \right) \delta \left( \dot{p}(x, t) + \frac{\delta H_j(u, p)}{\delta u(x, t)} \right)$$

with the total Hamiltonian

$$H_j(u, p) = \int dx \left\{ \frac{1}{2} p^2 + \frac{1}{2}(\nabla u)^2 + v(u) - ju \right\}. \quad (35)$$

Last one includes the energy $ju$ of quantum fluctuations. The measure (34) describes motion in the symplectic space $(u, p) \in V$. But it should be underlined that used expansion is not the Lagrange transformation. So, generally, it is quite possible, considering $x$ as the index of space sell, that not all of $p(x, t)$ are the independent variables. For this reason the measure (34) has mostly a Lagrange meaning.

The measure (34) contains following information $^{10,14}$:

a. Only the strict solutions of equations

$$\dot{u} - \frac{\delta H_j(u, p)}{\delta p} = 0, \quad \dot{p} + \frac{\delta H_j(u, p)}{\delta u} = 0 \quad (36)$$

at $j = 0$ should be taken into account. This ‘rigidness’ means absence in the formalism of the pseudo-solution (similar to multi-instanton, or multi-kink) contributions;

b. $\rho(\alpha, z)$ is described by the sum of all solutions of eq. (36), independently from theirs ‘nearness’ in the functional space;

c. The field disturbed by $j(x)$ belongs to the same manifold (topology class) as the classical field defined by (36) $^{10}$.

d. The consequence of properties b. and c. is the selection rule: quantum dynamics is realized in the coset space of highest dimension $^{10}$. This, excluding from consideration the pure ‘meson’ sector.
The particles density
\[ N(\alpha, z; u) = N_+(\alpha_+, z_+; u) + N_-(\alpha_-, z_-; u), \]  
(37)
where
\[ N_{\pm}(\alpha_{\pm}, z_{\pm}; u) = \int d\Omega_1(q)e^{i\alpha_{\pm}q z_{\pm}}|\Gamma(q; u)|^2, \]  
(38)
The ‘vertex’ \( \Gamma(q; u) \) is the function of the external particles momentum \( q \) and is the linear functional of \( u(x) \):
\[ \Gamma(q; u) = -\int dx e^{iqx}\frac{\delta S(u)}{\delta u(x)} = \int dx e^{iqx}(\partial^2 + m^2)u(x), \quad q^2 = m^2, \]  
(39)
for the mass \( m \) field. This parameter presents the momentum distribution of the interacting field \( u(x) \) on the remote hypersurface \( \sigma_{\infty} \) if \( u(x) \) is the regular function. Notice, the operator cancels the mass-shell states of \( u(x) \).

Generally \( \Gamma(q; u) \) is connected directly with external particles properties and sensitive to the symmetry of the interacting fields system \(^{26}\). The construction (39) means, because of the operator \((\partial^2 + m^2)\) and remembering that the external states should be mass-shell by definition \(^9\), the solution \( \rho(\alpha, z) = 0 \) is actually possible for particular topology (compactness and analytic properties) of quantum field \( u(x) \). So, \( \Gamma(q; u) \) carry following remarkable properties: (i) it directly defines the observables, (ii) is defined by the topology of \( u(x) \). Notice that the space-time topology of \( u(x, t) \) becomes important calculating integral (39) by parts. This procedure is available if \( u(x, t) \) is the regular function. But the quantum fields are always singular. Therefore, the solution \( \Gamma(q; u) = 0 \) is valid iff the semiclassical approximation is exact, i.e. the particle production is the pure quantum effect. Just this situation is realized in the soliton sector of sin-Gordon model.

Let \( G \) be the symmetry of the problem and let \( G_c \) be the symmetry of the solution \( u_c \). Then

**S2. The measure (34) admits the transformation:**
\[ u_c : (u, p) \rightarrow (\xi, \eta) \in W = G/G_c, \]  
(40)
and transformed measure has the form:
\[ DM(u, p) = \prod_{x, t \in C} d\xi(t)d\eta(t)\delta\left(\dot{\xi} - \frac{\delta h_j(\xi, \eta)}{\delta \eta}\right)\delta\left(\dot{\eta} + \frac{\delta h_j(\xi, \eta)}{\delta \xi}\right), \]  
(41)
where \( h_j(\xi, \eta) = H_j(u_c, p_c) \) is the transformed Hamiltonian.

\[
h_j(\xi, \eta; t) = h(\eta) - \int dx j(x, t) u_c(x; \xi, \eta)
\]

(42)

and \( u_c(x; \xi, \eta) \) is the soliton solution parametrized by \((\xi, \eta)\).

The proof of eq.(41) is the same as for the Coulomb problem considered in 14. But the case of the \((1+1)\)-dimensional model needs the additional explanations. First of all, one must introduce the function

\[
\Delta(u, p) = \int \prod_t \delta(u(x, t) - u_c(x; \xi, \eta)) \delta(p(x, t) - p_c(x; \xi, \eta)),
\]

(43)

The equalities

\[
u(x, t) = u_c(x; \xi, \eta), \quad p(x, t) = p_c(x; \xi, \eta)
\]

(44)

assume that for given \( u(x, t) \) and \( p(x, t) \) one can hide the \( t \) dependence into the \( N \) functions \( \xi = \xi(t) \) and \( \eta = \eta(t) \). It is assumed that this procedure can be done for arbitrary \( x \). In other respects functions \( u(x, t) \) and \( p(x, t) \), and therefore, \( u_c(x; \xi, \eta) \) and \( p(x; \xi, \eta) \), are arbitrary.

For more confidence, one may divide the space onto the \( N \) cells and to each \((u, p)\) we may adjust \((\xi, \eta)\). Quiet possible that \((\xi, \eta)\) are \( x \) independent. In this degenerate case \( \Delta \sim (\delta(0))^k \), where \( k \leq N \) is the degree of the degeneracy. We will omit the index \( x \) considering \((\xi, \eta)\) as the vector of the necessary dimension.

If \((\xi, \eta)\) are the solutions of (14), then

\[
\Delta(u, p) = \int \prod_t d\xi'(t)d\eta'(t) \delta(u^\xi \xi' + u^\eta \eta') \delta(p^\xi \xi' + p^\eta \eta') = \Delta_c(\xi, \eta) \neq 0,
\]

(45)

where, for instance, \( u^X_c = \partial u_c(x; \xi, \eta)/\partial X \), \( X = \xi, \eta \). Notice importance of last condition. If it fulfilled then one may insert into (28), with measure (14),

\[
1 = \frac{\Delta(u, p)}{\Delta_c(\xi, \eta)}
\]

(46)

and integrate over \( u(x, t) \) and \( p(x, t) \). Notice that the possible infinite factor \((\delta(0))^k\) would be canceled in the ratio (14).

The Jacobian of transformation
\[ J = \int \frac{DuDp}{\Delta_c(\xi, \eta)} \prod_{x,t} \delta \left( \dot{u} - \delta H_j(u, p) \right) \delta \left( \dot{p} + \delta H_j(u, p) \right) \times \delta(u(x, t) - u_c(x; \xi, \eta)) \delta(p(x, t) - p_c(x; \xi, \eta)), \] (47)

is proportional to functional \( \delta \)-functions again. To have the transformation, we should use the last two \( \delta \)-functions. Notice, if the first two \( \delta \)-functions are used to calculate \( J \), then last two \( \delta \)-functions realize the constraints. In result,

\[ J = \frac{1}{\Delta_c(\xi, \eta)} \prod_{x,t} \delta \left( \dot{u}_c - \frac{\delta H_j(u_c, p_c)}{\delta p_c} \right) \delta \left( \dot{p}_c + \frac{\delta H_j(u_c, p_c)}{\delta u_c} \right) \] (48)

It should be underlined that \( u_c \) and \( p_c \) are arbitrary functions of \( \xi \) and \( \eta \), i.e. on this stage we make the transformation of arbitrary functions \( u(x, t) \) and \( p(x, t) \) on the new arbitrary functions \( u_c(x; \xi, \eta) \) and \( p_c(x; \xi, \eta) \), where, generally speaking, \( \xi = \xi(x, t) \) and \( \eta = \eta(x, t) \). Then \( \Delta_c \) is the corresponding determinant.

The expression (48) can be rewritten identically to the form:

\[ J = \frac{1}{\Delta_c(\xi, \eta)} \int \prod_{x,t} d\xi'(t) d\eta'(t) \times \delta \left( \xi' - \left( \dot{\xi} - \frac{\delta h_j(\xi, \eta; t)}{\delta \eta} \right) \right) \delta \left( \eta' - \left( \dot{\eta} + \frac{\delta h_j(\xi, \eta; t)}{\delta \xi} \right) \right) \times \delta \left( u_c^{\xi'} + u_c^{\eta'} + \{u_c, h_j\} - \frac{\delta H_j}{\delta p_c(x, t)} \right) \times \delta \left( p_c^{\xi'} + p_c^{\eta'} - \{p_c, h_j\} + \frac{\delta H_j}{\delta u_c(x, t)} \right), \] (49)

where \( \{,\} \) is the Poisson bracket.

Let us assume now that the auxiliary function \( h_j(\xi, \eta; t) \) is chosen so that the equalities

\[ \{u_c, h_j\} = \frac{\delta H_j}{\delta p_c(x, t)}, \quad \{p_c, h_j\} = -\frac{\delta H_j}{\delta u_c(x, t)}. \] (50)

are satisfied identically. Then, taking into account the condition (45), one can find:

\[ J = \delta \left( \dot{\xi} - \frac{\delta h_j(\xi, \eta; t)}{\delta \eta} \right) \delta \left( \dot{\eta} + \frac{\delta h_j(\xi, \eta; t)}{\delta \xi} \right). \] (51)
This ends the transformation. Notice that the determinant \( \Delta_c \) was canceled identically.

The transformation specify by the equations (50) the function \( h_j \).

It assumes that one can find such functions \( u_c = u_c(x; \xi, \eta) \) and \( p_c = p_c(x; \xi, \eta) \), with property (15), that (50) has unique solution \( h_j(\xi, \eta; t) \).

Let us convert the problem assuming that just \( h_j \) is known. It is natural to assume that

\[
h_j(\xi, \eta; t) = H_j(u_c, p_c),
\]

then \( u_c \) and \( p_c \) are defined by the equations (50) and

\[
\dot{\xi} = \frac{\delta h_j(\xi, \eta; t)}{\delta \eta} \quad \dot{\eta} = -\frac{\delta h_j(\xi, \eta; t)}{\delta \xi}.
\]

It is not hard to see that (50) together with (53) are equivalent to incident equations (36). This is seen from the following chain of equalities:

\[
\dot{u}_c(x; \xi, \eta) = u_c^\xi \dot{\xi} + u_c^\eta \dot{\eta} =
\]

\[= u_c^\xi \frac{\partial h_j(\xi, \eta; t)}{\partial \eta} - u_c^\eta \frac{\partial h_j(\xi, \eta; t)}{\partial \xi} = \{u_c, h_j\} = \frac{\delta H_j}{\delta p_c(x, t)}
\]

and the same we have for \( p_c \). Therefore \((u_c, p_c)\) is the classical phase space flow and the space \( W_G \), labelled by \((\xi, \eta)\), is the coset space \( G/G_c \).

In result, new measure takes the form (41), i.e. \( \xi \) and \( \eta \) should obey the equations (53):

\[
\dot{\xi} = \omega(\eta) - \int dx j(x, t) \frac{\partial u_N(x; \xi, \eta)}{\partial \eta}, \quad \dot{\eta} = \int dx j(x, t) \frac{\partial u_N(\xi, \eta)}{\partial \xi},
\]

where \( \omega(\eta) \equiv \partial h(\eta)/\partial \eta \). Hence the source of quantum perturbations are proportional to the time-local tangent vectors

\[
\int dx \partial u_N(x; \xi, \eta)/\partial \eta, \quad \int dx \partial u_N(x; \xi, \eta)/\partial \xi
\]

to the soliton configurations. It suggests the idea\(^{14}\) to split the ‘Lagrange’ sources:

\[
j(x, t) \to (j_\xi, j_\eta)(t).
\]

The mechanism of splitting was described in\(^\text{10}\). Resulting operator \( O(u_c) \), defined in (28), has the same structure. But new perturbations
generating operator
\[ \hat{K}(e_\xi, e_\eta; j_\xi, j_\eta) = \frac{1}{2} Re \int_{C^+} dt \{ \hat{j}_\xi(t) \cdot \hat{e}_\xi(t) + \hat{j}_\eta(t) \cdot \hat{e}_\eta(t) \}. \] (55)

The measure takes the form:
\[ DM(\xi, \eta) = \prod_t d\xi(t)d\eta(t)\delta(\dot{\xi} - \omega(\eta) - j_\xi(t))\delta(\dot{\eta} - j_\eta(t)) \] (56)

The effective potential \( U = U(u_c; e_c) \) with
\[ e_c(x, t) = e_\xi(t) \cdot \frac{\partial u_N(x; \xi, \eta)}{\partial \eta(t)} - e_\eta(t) \cdot \frac{\partial u_N(x; \xi, \eta)}{\partial \xi(t)}. \] (57)

Notice that the space degree of freedom is disappeared from our consideration.

III. Multiple production in sin-Gordon model

We would consider the theory with Lagrangian
\[ L = \frac{1}{2}(\partial_\mu u)^2 + \frac{m^2}{\lambda^2}[\cos(\lambda u) - 1]. \] (58)

It is well known that this field model possess the soliton excitations in the (1+1) dimension.

Formally nothing prevents to linearize partly our problem considering the Lagrangian
\[ L = \frac{1}{2}[(\partial_\mu u)^2 - \alpha m^2 u^2] + \frac{m^2}{\lambda^2}[\cos(\lambda u) - 1 + \alpha \frac{\lambda^2}{2} u^2] \equiv S(u) - v(u) \] (59)

The last term \( v(u) = O(u^4) \) describes interactions. Corresponding vertex function is
\[ \Gamma(q; u) = \int dx dt e^{iqx} (\partial^2 + m^2)u(x, t), \quad q^2 = m^2. \] (60)

It should be noted here that chosen in (59) division onto the ‘free’ and ‘interaction’ parts did not affects the equation of motion, see (33), and effective potential, see (31), i.e. in this sense \( \alpha \) may be chosen arbitrary. But \( \alpha \) will arise in the definition of the mass: one should change \( m^2 \) →
This means that our $S$-matrix approach requires additional, external, normalization condition for the mass shell. We will choose $\alpha = 1$ assuming that $m$ is the measured mass of the ‘meson’.

We assume that $u(x, t)$ belongs to Schwarz space:

$$u(x, t)|_{|x| = \infty} = 0 \pmod{\frac{2\pi}{\lambda}}. \quad (61)$$

This means that $u(x, t)$ tends to zero ($\pmod{\frac{2\pi}{\lambda}}$) at $|x| \to \infty$ faster than any power of $1/|x|$.

The $\nu$-soliton classical Hamiltonian $h_\nu$ is the sum:

$$h_\nu(\eta) = \int dr \sigma(r) \sqrt{r^2 + m^2} + \sum_{i=1}^{\nu} h(\eta_i), \quad (62)$$

where $\sigma(r)$ is the continuous spectrum and $h(\eta)$ is the soliton energy. Notice absence of the energy of soliton interactions.

The $\nu$-soliton solution $u_\nu$ depends on the $2\nu$ parameters. Half of them $\nu$ can be considered as the position of solitons and other $\nu$ as the solitons momentum. Generally, at $|t| \to \infty$ the $u_\nu$ solution decomposed on the single solitons $u_s$ and on the double soliton bound states $u_b$:

$$u_\nu(x, t) = \sum_{j=1}^{n_1} u_{s,j}(x, t) + \sum_{k=1}^{n_2} u_{b,k}(x, t) + O(e^{-|t|}) \quad (63)$$

For this reason the one soliton $u_s$ and two-soliton bound state $u_b$ would be the main elements of our formalism. Its $(\xi, \eta)$ parametrizations, i.e. the solution of eq. (50), has the form 27:

$$u_s(x; \xi, \eta) = -\frac{4}{\lambda} \arctan\{\exp(mx \cosh \beta \eta - \xi\}, \quad \beta = \frac{\lambda^2}{8} \quad (64)$$

and

$$u_b(x; \xi, \eta) = -\frac{4}{\lambda} \arctan \left\{ \tan \frac{\beta \eta_2}{2} \frac{mx}{2} \sinh \frac{\beta \eta_2}{2} \cos \frac{\beta \eta_2}{2} - \xi_2 \right\}. \quad (65)$$

The $(\xi, \eta)$ parametrization of solitons individual energies $h(\eta)$ takes the form:

$$h_s(\eta) = \frac{m}{\beta} \cosh \beta \eta, \quad h_b(\eta) = \frac{2m}{\beta} \cosh \frac{\beta \eta_1}{2} \sin \frac{\beta \eta_2}{2} \geq 0.$$
The bound-state energy \( h_b \) depends on \( \eta_2 \) and \( \eta_1 \). First one defines inner motion of two bounded solitons and second one the bound states center of mass motion. Correspondingly we will call this parameters as the internal and external ones. Note that the inner motion is periodic, see (65).

Following to the definition of the Dirac measure one should sum over all solutions of the Lagrange equation, see the property b. in Sec.2. As follows from the equality:

\[
\sum_{\{u_c\}} = \int_{W_G} d\xi_0 d\eta_0 \sigma(u; \xi_0, \eta_0)
\]

we should define the density \( \sigma(u; \xi_0, \eta_0) \) of states in the element of the coset space \( W_G \). The Faddeev-Popov ansatz is used for this purpose 4.

In our approach, performing the transformation into the coset space \( W_G \), we define the density \( \sigma(u; \xi_0, \eta_0) \). Indeed, using the definition:

\[
\int D\!\!x \prod_t \delta(\dot{x}) = \int \!\!dx(0) = \int \!\!dx_0
\]

the functional integrals with measure (56) are reduced to the ordinary ones over the initial data \((\xi_0, \eta_0)\).

But it is important here to trace on the following question. One can note that, at first glance, integration over \((\xi, \eta)_0\) may only give \( \rho \sim V_0^1 \), where \( V_0 \) is the zero modes volume, i.e. is a volume of the \( W_G \) space. On other hand, as follows from definition of \( \rho \sim |a_{nm}|^2 \), one may expect that \( \rho \sim V_0^2 \). This discrepancy should have an explanation.

Remembering definition of \( \rho \) as the squire of amplitudes, we should defined the contributions on the whole time contour \( C = C_+ + C_- \), see (13), to take into account the input condition that the trajectories \( u_+(t \in C_+) \) and \( u_-(t \in C_-) \) are absolutely independent in the frame of the ‘closed-path’ boundary condition (27):

\[
u_c(x, t \in \partial C_+) = u_c(x, t \in \partial C_-), \tag{66}
\]

where \( \partial C_\pm \) is the boundary of \( C_\pm \). Other directions to the \( \sigma|\text{infty} \) are not important here.

Then, if we introduce \((\xi, \eta)(t \in C_\pm)|_0 \equiv (\xi_0, \eta_0)_\pm\), one should have in mind that, generally speaking, \((\xi_0, \eta_0)_+ \neq (\xi_0, \eta_0)_-\) and the integration over them should be performed independently. This may explain above discrepancy and one should have \( \rho \sim V_0^2 \).
It is not hard to see that for our topological solitons the condition (66) leads to the equalities:

$$(\xi_0, \eta_0)^+ = (\xi_0, \eta_0)^- = (\xi_0, \eta_0). \quad (67)$$

To see this it is enough to inserting (64), or (65), into (66) and take into account that at $t \in \partial C^\pm$ the estimation (63) is right.

Solution (67) means that, for arbitrary functional $F(\xi, \eta)$,

$$\int \prod_{t \in C^+ + C^-} d\xi d\eta \delta(\dot{\xi}) \delta(\dot{\eta}) F(\xi, \eta) = \int d\xi_0 d\eta_0 \int d\xi_0 d\eta_0 F(\xi_0, \eta_0). \quad (68)$$

Therefore, $\rho \sim V_0^2$. We will put out the integrals over inessential variables $\xi_{0+}$ and $\eta_{0+}$.

It should be underlined that (67) is the consequence of the conservation of the topological charge: the solitons by this reason are the stable formation and, therefore, to satisfy the closed path boundary condition, one should have (67).

Performing the shifts:

$$\xi_i(t) \rightarrow \xi_i(t) + \int dt' g(t - t') j_{\xi,i}(t') \equiv \xi_i(t) + \xi_i'(t),$$

$$\eta_i(t) \rightarrow \eta_i(t) + \int dt' g(t - t') j_{\eta,i}(t') \equiv \eta_i(t) + \eta_i'(t),$$

we can get the Green function $g(t - t')$ into the operator exponent:

$$\hat{K}(e_j) = \frac{1}{2} \int dt dt' \Theta(t - t') \{ \dot{\xi}'(t') \cdot \hat{e}_{\xi}(t) + \dot{\eta}'(t') \cdot \hat{e}_{\eta}(t) \}. \quad (69)$$

since the Green function $g(t - t')$ of the transformed theory is the step function $^{10}$:

$$g(t - t') = \Theta(t - t') \quad (70)$$

Such Green function allows to shift $C^\pm$ on the real-time axis. This, noting (67), excludes doubling of the degrees of freedom.

Notice the Lorentz noncovariantness of our perturbation theory with Green function (70).

The measure takes the form:

$$D^\nu M(\xi, \eta) = \prod_{i=1}^\nu \prod_t d\xi_i(t) d\eta_i(t) \delta(\dot{\xi}_i - \omega(\eta + \eta')) \delta(\dot{\eta}_i). \quad (71)$$
The interactions are described by

\[ U(u_\nu; e_c) = -\frac{2m^2}{\lambda^2} \int dx dt \sin \lambda u_\nu \sin \lambda e_c - \lambda e_c \]  

(72)

with

\[ u_\nu = u_\nu(x; \xi + \xi', \eta + \eta') \]  

(73)

and \( e_c \) was defined in (57).

The equations:

\[ \dot{\xi}_i = \omega(\eta_i + \eta'_i) \]  

(74)

are trivially integrable. In quantum case \( \eta'_i \neq 0 \) this equation describes motion in the nonhomogeneous and anisotropic manifold. So, the expansion over \( (\hat{\xi}', \hat{\xi}, \hat{\eta}', \hat{\eta}) \) generates the local in time fluctuations of \( W_G \) manifold. The weight of this fluctuations is defined by \( U(u_\nu; e_c) \).

Expansion of \( \exp\{\hat{K}(j_\nu)\} \) gives the ‘strong coupling’ perturbation series. The analyses shows that

S3. Action of the integro-differential operator \( \hat{O} \) leads to following representation:

\[ \rho(\alpha, z) = \int_{W_G} \left\{ d\xi(0) \cdot \frac{\partial}{\partial \xi(0)} R^\xi(\alpha, z) + d\eta(0) \cdot \frac{\partial}{\partial \eta(0)} R^\eta(\alpha, z) \right\}. \]  

(75)

This means that the contributions into \( \rho \) are accumulated strictly on the boundary ‘bifurcation manifold’ \( \partial W_G \). The prove of this important result was given in \(^{10,14} \) and we will use it without comments.

We would divide calculations on two parts. First of all, we would consider the semiclassical approximation and then we will show that this approximation is exact.

Performing the last integration we find:

\[ \rho(\alpha, z) = \int \prod_{i=1}^{n} \{d\xi_0 d\eta_0\} e^{-i\hat{K}} e^{i\hat{S}_O(u_\nu)} e^{-iU(u_\nu; e_c)} e^{N(\alpha, z; u_\nu)} \]  

(76)

where

\[ u_\nu = u_\nu(\eta_0 + \eta', \xi_0 + \omega(t) + \xi'). \]  

(77)

and

\[ \omega(t) = \int dt' \Theta(t - t') \omega(\eta_0 + \eta')(t') \]  

(78)

In the semiclassical approximation \( \xi' = \eta' = 0 \) we have:

\[ u_\nu = u_\nu(x; \eta_0, \xi_0 + \omega(\eta_0)t). \]  

(79)
Notice that the surface term
\[ \int dx^\mu \partial_\mu (e^{iqx} u_\nu) = 0. \] (80)
Then
\[ \int d^2 x e^{iqx} (\partial^2 + m^2) u_\nu(x,t) = -(q^2 - m^2) \int d^2 x e^{iqx} u_\nu(x,t) = 0 \] (81)
since \( q^2 \) belongs to the mass shell by definition. The condition (80) is satisfied for all \( q_\mu \neq 0 \) since \( u_\nu \) belong to the Schwarz space. Therefore, in the semiclassical approximation \( R^c(\alpha, z) \) is the trivial function of \( z \):
\[ \partial R^c(\alpha, z) / \partial z = 0. \]

Expanding the operator exponent in (76), we find that action of the operators \( \hat{\xi}', \hat{\eta}' \) create the terms
\[ \sim \int d^2 x e^{iqx} \theta(t - t') (\partial^2 + m^2) u_\nu(x,t) \neq 0. \] (82)
So, generally \( R(\alpha, z) \) is the nontrivial function of \( z \).

Now we will show that the semiclassical approximation is exact in the soliton sector of the sin-Gordon model. The structure of the perturbation theory is readily seen in the ‘normal- product’ form:
\[ R(\alpha, z) = \sum_\nu \int \prod_{i=1}^N \{d\xi_0 d\eta_0\}_i : e^{-iU(u_\nu ; j/2i)} e^{iS_0(u_\nu)} e^{N(\alpha,z;u_\nu)} :, \] (83)
where
\[ \hat{j} = \hat{j}_\xi \cdot \partial u_\nu / \partial \eta - \hat{j}_\eta \cdot \partial u_\nu / \partial \xi = \Omega \hat{j}_X \partial u_\nu / \partial X \] (84)
and
\[ \hat{j}_X = \int dt' \Theta(t - t') \hat{X}(t') \] (85)
with the 2N-dimensional vector \( X = (\xi, \eta) \). In eq.(84) \( \Omega \) is the ordinary symplectic matrix.

The colons in (83) mean that the operator \( \hat{j} \) should stay to the left of all functions. The structure (84) shows that each order over \( \hat{j}_X_i \) is proportional at least to the first order derivative of \( u_\nu \) over conjugate to \( X_i \) variable.

The expansion of (83) over \( \hat{j}_X \) can be written using in the form:
\[ \rho(\alpha, z) = \sum_\nu \int \prod_{i=1}^N \{d\xi_0 d\eta_0\}_i \left\{ \sum_{i=1}^{2\nu} \partial \over \partial X_{0i} P_{X_i}(u_\nu) \right\}, \] (86)
where $P_{X_i}(u_\nu)$ is the infinite sum of the ‘time-ordered’ polynomial over $u_\nu$ and its derivatives $^{14}$. The explicit form of $P_{X_i}(u_\nu)$ is unimportant, it is enough to know, see (84), that

$$P_{X_i}(u_\nu) \sim \Omega_{ij} \frac{\partial u_\nu}{\partial X_{0j}}. \quad (87)$$

Therefore,

$$\frac{\partial}{\partial z} R(\alpha, z) = 0 \quad (88)$$

since (i) each term in (86) is the total derivative, (ii) we have (87) and (iii) $u_\nu$ belongs to Schwarz space.

**IV. Conclusion**

We would like to conclude this paper noting the role of the coset space $G/G_c$ topology. It was shown that if

(a) $W_G = G/G_c \neq \emptyset$,
(b) $W_G = T^*V$ is the simplectic manifold,
(c) $\partial u_c$ is the flow,
(d) $\partial u_c \cap \partial W_G = \emptyset$,

then the semiclassical approximation is exact.

For this reason, being absolutely stable, ‘topological solitons’ are unable to describe the multiple production processes. This property of the exactly integrable models was formulated also as the absence of stochasticization in the integrable systems $^{28}$. The $O(4) \times O(2)$-invariant solution of $O(4,2)$-invariant theories $^{29}$ is noticeably more interesting from this point of view $^{30}$.

**Acknowledgement**

We acknowledged to members of the seminar ‘Symmetries and integrable systems’ of the N.N.Bogolyubov Laboratory of theoretical physics (JINR) for important discussions. We would like to thank V.G.Kadyshevski for fruitful interest to described technique and underlign idea. One of us (JM) was partly granted by Georgian Acad. of Sciences.
A Appendix. Derivation of eq.(29)

The generating functional (24) can be written in the form:

\[ \rho(\beta, z) = e^{-\tilde{n}(s)(\beta,z;\varphi)}\rho_0(\varphi), \]  

(A.1)

where the particles number operator

\[ \tilde{n}(s)(\beta, z; \varphi) = \tilde{n}(s)(\beta_+, z_+; \varphi) + \tilde{n}(s)^*(\beta_-, z_-; \varphi), \]  

(A.2)

and

\[ \tilde{n}(s)(\beta_+, z_+; \varphi_+) = \int d\Omega_1(q) \hat{\varphi}^*_+(q)\hat{\varphi}_-(q)e^{-\beta_+\epsilon(q)}z_+(q) \]  

(A.3)

is the produced particles number operator.

The functional \( \rho_0 \) was introduced in (25):

\[ \rho_0(\varphi) = Z(\varphi_+)Z^*(-\varphi_-) = \int D\varphi_+ D\varphi_- e^{iS_+(\varphi_+)-iS_-(\varphi_-)}e^{-iV_+(\varphi_+)+iV_-(\varphi_-)}. \]  

(A.4)

So, the integration over \( u_+ \) and \( u_- \) is not performed independently: one should take into account the boundary condition (27). We can perform in this integrals the linear transformation:

\[ u_\pm(x) = u(x) \pm \phi(x). \]  

(A.5)

Then the boundary condition (27) leads to equality:

\[ \phi(x \in \sigma_\infty) = 0, \]  

(A.6)

leaving \( u(x \in \sigma_\infty) \) arbitrary. Last one means that the integration over this ‘turning-point’ field \( u(x \in \sigma_\infty) \) should be performed, see Sec.3.

Let us extract in the exponents (A.4) the linear over \( (\phi + \varphi) \) term:

\[ V_+(u + (\phi + \varphi)) - V_-(u - (\phi + \varphi)) = \]

\[ + U(u, \phi + \varphi) + 2\text{Re} \int_{C_+} dx(\phi(x) + \varphi(x))v'(u), \]  

(A.7)

and

\[ S_+(u + \varphi) - S_-(u - \varphi) = S_0(u) - 2i\text{Re} \int_{C_+} dx\varphi(x)(\partial^2_x + m^2)u(x). \]  

(A.8)
where 
\[ 2\text{Re} \int_{C^+} = \int_{C^+} + \int_{C^-}. \]

Notice that the generally speaking, \( S_0(u) \neq 0 \) if the topology of field \( u(x) \) is nontrivial, see Sec. 3.

The expansion over \((\phi + \varphi)\) can be written in the form:
\[ e^{-iU(u,\phi+\varphi)} = e^{\frac{1}{2\pi} \text{Re} \int_{C^+} dx j(x) \varphi'(x)} e^{i2\text{Re} \int_{C^+} dxdt j(x)(\phi(x)+\varphi(x))} e^{-iU(u,\varphi')}, \quad (A.9) \]

where \( j(x) \), \( \varphi'(x) \) are the variational derivatives. The auxiliary variables \((j, \varphi')\) must be taken equal to zero at the very end of calculations.

In result,
\[ \rho_0(\phi) = e^{\frac{1}{2\pi} \text{Re} \int_{C^+} dx j(x) \varphi'(x)} \int DU e^{is_0(u)} e^{-iU(u,\varphi)} e^{i2\text{Re} \int_{C^+} dx(j(x) - v'(u))\phi(x)} \times \]
\[ \times \prod_x \delta(\partial^2_{\mu}u + m^2u + v'(u) - j), \quad (A.10) \]

where the functional \( \delta \)-function was defined by the equality:
\[ \prod_x \delta(\partial^2_{\mu}u + m^2u + v'(u) - j) = \int D'\phi e^{-2i\text{Re} \int_{C^+} dx(\partial^2_{\mu}u + m^2u + v'(u) - j)\varphi(x)}, \quad (A.11) \]

where the prime means that \( D'\phi \) does not includes the integration over \( \phi(x \in \sigma_\infty) \). This condition is not seen in the functional \( \delta \)-function because of the definition:
\[ \int \prod_x du(x) \delta(\partial_{\mu}u(x)) = \int du(x_{\mu} \in \sigma_\infty). \]

The eq. (A.10) can be rewritten in the equivalent form:
\[ \rho_0(\phi) = e^{-i \hat{K}(j,\varphi)} \int DM(u)e^{is_0(u) - iU(u,\varphi)} e^{i2\text{Re} \int_{C^+} dx \varphi(x)(\partial^2_{\mu} + m^2)u(x)} \quad (A.12) \]

because of the \( \delta \)-functional measure:
\[ DM(u) = \prod_x du(x) \delta(\partial^2_{\mu}u + m^2u + v'(u) - j), \quad (A.13) \]

with
\[ \hat{K}(j,\varphi) = \frac{1}{2} \text{Re} \int_{C^+} dx j(x) \varphi(x). \quad (A.14) \]

Notice at the end that the contour \( C^+ \) in (A.14) can not be shifted on the real time axis since the Green function of the equation
\[ \partial^2_{\mu}u + m^2u + v'(u) = j \]
is singular on the light cone.

The action of operator $\mathbf{N}(\beta, z; \hat{\phi})$ maps the interacting fields system on the physical states. Last ones are ‘marked’ by $z_\pm$ and $\beta_\pm$. The operator exponent is the linear functional over $\phi$ and this allows easily find (28).
The developed below formalism is not manifestly Lorentz covariant. By this reason we decouple the space component $x$ and time $t$. But, if the expression contains the $x$ dependence only, then in this expression $x$ is the 2-dimensional vector.

18There are the remarkable attempts to construct a geometrical approach to quantum mechanics, e.g. T.W.Kibble, Comm. Math. Phys., 65, 189 (1979), J.Anandan, Found. Phys., 21, 1265 (1991), and field theory, e.g. N.P.Konopleva and V.N.Popov, Gauge fields (Harward Acad. Publ., Chur-London-New York, 1981). Note that our interpretation is dealing with the classical phase-space flows. By this reason, in contrast with above mentioned approaches, the finite dimensional manifolds only, as in classical mechanics, would arise.

Following toy analogy with ferromagnetic may be useful. So, the external magnetic field $\mathcal{H} \sim \bar{\mu}$, where the average spin $\bar{\mu}$ is the magnetics order parameter, and the phase transition means that $\bar{\mu} \neq 0$. Offered $\Gamma(q, u)$ has the same meaning as $\mathcal{H}$.
