We propose to implement tunable interaction of superconducting flux qubits with cavity-assisted interaction and strong driving. The qubits have a three-level Lambda configuration, and the decay of the excited state will be greatly suppressed due to the effective large detuning. The implemented interaction is insensitive to the cavity field state and can be controlled by modulating the phase difference of the driving fields of the qubits. In particular, our scheme is based on the typical circuit QED setup and thus will provide a simple method towards the tunable interaction of superconducting qubits. Finally, we consider the generation of two and four qubits entangled states with the constructed interaction under the influence of typical decoherence effects.

Keywords: Circuit QED; Tunable interaction; Superconducting flux qubit

Recently, with highly developed fabrication techniques and newly designed architecture, superconducting qubit is recognized as one of the most promising candidates for implementation of the on-chip quantum computation [1-4]. To implement quantum networks and distributed quantum information processing, cavity-assisted coupling is preferred [5-12], where a microwave photon can be an ideal flying qubit [13]. Moreover, this architecture has several practical advantages including strong coupling strength, immunity to noises, and suppression of spontaneous emission. As it is well known, the ability of controlling qubit-qubit and qubit-cavity interactions is generic to all physical implementation of quantum computer and simulators [14-17]. However, the cavity-induced interaction is of the always-on nature, and thus one needs to find practical ways of switching and/or tuning this interaction.

Conventionally, in the circuit QED scenario, the qubit-cavity interaction is effectively tuned off by dispersive interaction [8]. This requires one can tune the energy splitting of the superconducting qubit and/or the cavity. The more severe problem is that this switch will become less effective in the case of more than single qubit in the cavity. In this case, qubits can be effectively interacted with each other by exchange the virtual photon of the cavity [18, 19], and thus may sweep the switch effect. Therefore, one needs more accurate tunable qubit-cavity interaction. With this tunable qubit-cavity interaction, one may achieve tunable qubit-qubit interaction as the coupling strength of which is determined by the qubit-cavity coupling strengths [18]. However, previous investigations [20-26] are based on increasing the complexity of their setups to achieve this tunability, e.g. introduce a SQUID serves as a tunable coupler and thus will inevitably introduce additional noise for the qubits. Moreover, there is no investigation in tunable interaction of superconducting qubits in a cavity.

Here, we propose to directly implement tunable interaction for superconducting qubits from the always-on qubit-cavity interaction in circuit QED. To obtain interaction among qubits, we use the dispersive qubit-cavity interaction together with microwave-fields-induced strong driving. In particular, the obtained coupling strength of the superconducting qubits can be tuned in a continuous way by modulating the phase difference of the effective qubit-cavity interaction. The phases come from the external driving fields which can be tuned individually and thus will provide a simple method towards the tunable interaction of superconducting qubits. The superconducting qubits considered here are flux qubits with three energy levels in effect [27-29]. The two driving fields of a qubit compete with the qubit-cavity interaction and lead the whole interaction to a collective form, i.e. collective qubit-states-dependent displacement of the cavity field. In this way, the cavity state traverses cyclically and returns to its original state at some intervals and leaves an geometric phase on the collective states of the involved qubits [30-36], which avoids the cooling of the cavity to its exact ground state beforehand and results in high-fidelity operation on the qubits.

We now turn to our proposal. The superconducting qubits are flux qubits with three energy levels in a Lambda configuration labelled by |0⟩, |1⟩ and |e⟩, as illustrated in Fig. 1(a). When the external magnetic flux Φq pierced through the qubit loop is deviated from the symmetry point with f = Φq/Φ0 = 1/2, the selection rules of the qubit will be broken [27], allowing for the coexistence of one- and two-photon processes, i.e. microwave-induced transitions between any two energy levels are possible. In our implementation, |0⟩ and |1⟩ are encoded as our qubit states, which are coupled with a resonant microwave field with strength Ω. Here, we choose f to be slightly deviated from 1/2, which leads the qubit energy splitting ωq to be in the sub-GHz level [27] and the three levels form a Delta type of transition configuration. In addition, the qubits are capacitively coupled to a one-dimensional superconducting cavity forming the typical circuit QED archite-
induced coupling with frequency \( \omega_c \) (\( \omega_1 \)) is coupled by a superconducting cavity (a microwave field) with frequency \( \omega_c \) (\( \Omega_L \)) and coupling strength \( G \) (\( \Omega_L \)). Then, in units of \( \hbar \), the system is described by

\[
H_S = H_0 + \sum_{j=1}^{N} \left[ \frac{\Omega_j}{2} e^{-i\omega_j} |1\rangle \langle 0| + G_j a|e\rangle \langle 0| \right]
+ \Omega_{L,j} e^{-i(\omega_c+\phi_j)} |e\rangle \langle 1| + \text{H.c.},
\]

where \( H_0 = \omega_c a^+a + \sum_i \omega_i |i\rangle \langle i| \) is the free Hamiltonian where \( a^+ (a) \) is the creation (annihilation) operator of the cavity field and \( \omega_i \) is the frequency of \( i \)th energy level with \( i \in \{0, 1, e\} \). Note that both the \( |0\rangle \rightarrow |e\rangle \) and \( |1\rangle \rightarrow |e\rangle \) couplings are far-off resonant from their transition frequencies so that the excited state \( |e\rangle \) state can be adiabatically eliminated \([37, 39]\) and thus suppress the influence of the spontaneous emission effect to our implementation. Within the rotating-wave approximation, the interaction Hamiltonian in the interaction picture, with respect to \( H_0 \), can be written as

\[
H_I = \sum_{j=1}^{N} \frac{\Omega_j}{2} \sigma_j^+ + 2 \eta_j \left( a \sigma_j^+ e^{i(\delta t + \phi_j)} + \text{H.c.} \right),
\]

where \( \sigma_j^+ = |1\rangle \langle 0|_j, \sigma_j^- = |0\rangle \langle 1|_j, \) and

\[
\eta_j = \frac{G_j \Omega_{L,j}}{2} \left( \frac{1}{\Delta_j + \phi_j} + \frac{1}{\Delta_j} \right) \approx \frac{G_j \Omega_{L,j}}{\Delta_j}
\]

with \( \Delta_j = \omega_{1,j} - \omega_{L,j}, \delta_j = \omega_{0,j} + \omega_{L,j} - \omega_c \) and \( \Delta_j \gg \delta_j \). Therefore, we realize the circuit QED system with microwave driving, as shown in Fig. (b), where the effective cavity-induced coupling \( \eta_j \) can be tuned by the \( \Omega_{L,j} \) detunings. In addition, the phase factors \( \delta_j \) can be tuned individually.

We next detail our further treatments. Assuming \( \eta_j = \eta \) and \( \delta_j = \delta \), in the interaction picture with respect to the first term, the interacting Hamiltonian in Eq. (2) reads

\[
H_I = \eta \sum_{j=1}^{N} \left[ a e^{i(\delta t + \phi_j)} + a^+ e^{-i(\delta t + \phi_j)} \right] \sigma_j^+ + \eta \sum_{j=1}^{N} \left[ a e^{i(\delta t + \phi_j)} \left( e^{i\delta t} + \right)_{j} \langle - | e^{-i\delta t} - | j \langle + \right) + \text{H.c.} \right].
\]

where \( |\pm\rangle = (|0\rangle \pm |1\rangle)/\sqrt{2} \). In the case of strong driving, \( \Omega \gg \{ \delta, \eta \} \), we can omit the fast oscillation terms with frequencies \( \Omega \pm \delta \), i.e., the second line of Hamiltonian \([3]\), and then we obtain

\[
H_2 = \eta \sum_{j=1}^{N} \left[ a e^{i(\delta t + \phi_j)} + a^+ e^{-i(\delta t + \phi_j)} \right] \sigma_j^+, \tag{5}
\]

which is in the form of spin-dependent dipole force for the cavity field. This force will lead the cavity state return to its original state periodically in phase space. To see this, we consider the case that only the first qubit is subjected to the force in the \( xp \) phase space with \( \phi_1 = 0 \). In this case, the Hamiltonian \([5]\) reduces to

\[
H_3 = \sqrt{2}\eta |\cos(\delta t) x - \sin(\delta t) p| \sigma_j^+, \tag{6}
\]

where we have defined the dimensionless position and momentum operators, \( x = (a^t - a) / \sqrt{2} \) and \( p = i(a^t + a) / \sqrt{2} \). In the phase space, the effect of Hamiltonian \([6]\) is to perform the displacements of

\[
(x_0, p_0) \rightarrow \left( (x_0 + x(t)) \sigma_j^+, \left( p_0 + p(t) \right) \sigma_j^+ \right) \tag{7}
\]

with \( x(t) = \sqrt{2}\eta |1 - \cos(\delta t)| / \delta \) and \( p(t) = \sqrt{2}\eta \sin(\delta t) / \delta \), which entangles the cavity with the qubit. Depending on the spin states \( |\pm\rangle \), the cavity is displaced to form a closed trajectory, see Fig. (c) for \( x_0 = p_0 = 0 \). When incorporating many qubit, this spin-dependent force can be used to generate many-body entangled state of the qubits, i.e., introduce nontrivial interaction among qubits. As \( x(t) \) and \( p(t) \) are both periodical functions, the cavity will return to its original state once \( \delta t_n = 2n\pi \) with \( n = 1, 2, 3, \ldots \), i.e., the evolution is insensitive to the cavity field state, and thus one may expect that it is more robust, which mitigates the thermal limitation of the cavity in engineering quantum states. Therefore, at these time intervals, the net effect of Hamiltonian \([5]\) makes the qubit system pick a geometric phase \([40]\) and leads to fast geometric gate of the qubits.

We next exemplify the nontrivial interaction with \( N = 2 \). When \( \delta t_n = 2n\pi \) and \( \phi_j = 0 \), the induced evolution operator for the Hamiltonian in Eq. \([5]\) is

\[
U(\theta) = \exp \left( -i\theta \sigma_j^+ \sigma_j^+ \right), \tag{8}
\]
where \( \theta = \lambda \tau_n \cos \varphi_1 \) with \( \lambda = 2\eta^2/\delta \) and \( \varphi_1 = \phi_1 - \phi_2 \).

Therefore, the corresponding effective Hamiltonian of the operator in Eq. (8) is
\[
H_4 = \lambda \cos \varphi_1 \sigma_1^x \sigma_2^x,
\]
where \( \varphi_1 \) can be used to tune the effective coupling strength. However, the effective Hamiltonian only holds for the time intervals of \( \tau_n \). When \( \delta \gg \eta \), the effective Hamiltonian will hold at approximately any time due to the fact that \( \tau_n \) will be much smaller than the time scale of the periodicity of the effective Hamiltonian, which is on the order of \( 1/\lambda \). Therefore, our scheme is faster comparing with previous implementations involving large detuned qubit-cavity interaction.

For an initial state of \(|00\rangle\), governed by the Hamiltonian in Eq. (5), the final state will be a maximally entangled Bell-type state when \( \theta = \pi/4 \) as
\[
|\psi_f\rangle = U\left(\frac{\pi}{4}\right)|00\rangle = \frac{1}{\sqrt{2}}(|00\rangle + i|11\rangle).
\]

When \( \Omega_L = 2\pi \times 0.1 \text{ GHz} \) and \( \Delta = 100\Omega_L \), \( \eta \approx G/10 = 2\pi \times 10 \text{ MHz} \) for a moderate cavity-assisted coupling strength of \( G = 2\pi \times 0.1 \text{ GHz} \) [12]. When \( \Omega \gg \Delta \), the assumption \( \{\Omega, \Delta\} \gg \delta \) is well satisfied. In order to derive Eq. (5), we have discarded the terms in the second line of Eq. (4), which induce Stark shifts on the states of \(|\pm\rangle\). In the above example of generating Bell state, this neglect will introduce an infidelity approximately proportional to \((\eta/\Omega)^2\), which is negligible small for large ratio of \( \Omega/\eta \). In addition, \( \theta = \pi/4 \) can be realized by choosing \( \delta = 4\sqrt{\eta} \), which further leads to \( \tau_n = \sqrt{\eta}\pi/(2\eta) \). Therefore, for \( n = 1 \) (\( \delta = 4\eta \)), the minimal generation time of the entangled state is \( \tau_1 = \pi/(2\eta) \), which is much faster comparing with the usual large detuning schemes (\( \delta \gg \eta \)).

The performance of the entangling gate in Eq. (8) can be evaluated by considering the influence of dissipation using the quantum master equation of
\[
\dot{\rho} = i[\rho, H_2] + \frac{\kappa}{2} \mathcal{L}(\alpha) + \sum_{j=1}^{2} \left[ \frac{\gamma_1}{2} \mathcal{L}(\sigma_j^-) + \frac{\gamma_2}{2} \mathcal{L}(\sigma_j^+) \right]
\]
where \( \rho \) is the density matrix of the considered system, \( \mathcal{L}(A) = 2A\rho A^\dagger - A^\dagger A\rho - \rho A^\dagger A \) is the Lindblad operator.
which can be universal for quantum computation purpose.

In summary, we have proposed to implement tunable interaction of superconducting flux qubits with cavity-assisted interaction and strong driving. The decay of the excited state of the flux qubits can be greatly suppressed due to the effective large detuning. The implemented interaction is insensitive to the cavity field state and can be controlled by modulating the phase difference of the driving fields of the qubits. In particular, our scheme is based on the typical circuit QED setup and thus will provide a simple method towards the tunable interaction of superconducting qubits. Finally, we consider the generation of entangled states from the tunable interaction under typical decoherence effects and show that high-fidelity entangled state can be obtained.
