Charmless Hadronic Decays of $B$ Mesons
to a Pseudoscalar and a Tensor Meson

Abstract

We study two-body charmless hadronic decays of $B$ mesons to a pseudoscalar meson ($P$) and a tensor meson ($T$) in the frameworks of both flavor SU(3) symmetry and generalized factorization. Certain ways to test validity of the generalized factorization are proposed, based on the flavor SU(3) analysis. We present a set of relations between a flavor SU(3) amplitude and a corresponding amplitude in the generalized factorization which bridge both approaches in $B \to PT$ decays. The branching ratios and CP asymmetries are calculated using the full effective Hamiltonian including all the penguin operators and the form factors obtained in the non-relativistic quark model of Isgur, Scora, Grinstein and Wise. We identify the decay modes in which the branching ratios and CP asymmetries are expected to be relatively large.

I. INTRODUCTION

The CLEO Collaboration has reported new experimental results on the branching ratios of a number of exclusive $B$ meson decay modes where $B$ decays into a pair of pseudoscalars ($P$), a vector ($V$) and a pseudoscalar meson, or a pair of vector mesons. Motivated by the new data, many works have been done to understand those exclusive hadronic $B$ decays in the framework of the generalized factorization, QCD factorization, or flavor SU(3) symmetry. In the next few years $B$ factories operating at SLAC and KEK will provide plenty of new experimental data on $B$ decays. It is expected that improved new bound will be put on the branching ratios for various decay modes and many decay modes with small branching ratios will be observed for the first time. Thus more information on rare decays of $B$ mesons will be available soon.

There have been a few works [1–3] studying two-body hadronic $B$ decays involving a tensor meson $T (J^P = 2^+)$ in the final state using the non-relativistic quark model of Isgur, Scora, Grinstein and Wise (ISGW) [4] with the factorization ansatz. Most of them studied $B$ decays involving a $b \rightarrow c$ transition, to which only the tree diagram contributes. In a recent work [3], the authors considered the Cabibbo-Kobayashi-Maskawa (CKM)-suppressed hadronic $B$ decays involving a $b \rightarrow u$ transition as well as a $b \rightarrow c$ transition. However, they included only the tree diagram contribution even in charmless $B$ decays to $PT$ and $VT$, such as $B \rightarrow \eta^{(t)}a_2$ and $B \rightarrow \phi f_2^{(t)}$. In most cases of the charmless $\Delta S = 0$ processes, the dominant contribution arises from the tree diagram and the contributions from the penguin diagrams are very small. But in some cases such as $B \rightarrow \eta^{(t)}a_2$ and $\eta^{(t)}f_2^{(t)}$, the penguin diagrams provide sizable contributions. Furthermore, in the charmless $|\Delta S| = 1$ decay processes, the penguin diagram contribution is enhanced by the CKM matrix elements $V_{tb}^* V_{ts}$ and becomes dominant.

Experimentally several tensor mesons have been observed [3], such as the isovector $a_2 (1320)$, the isoscalars $f_2(1270)$, $f_2' (1525)$, $f_2 (2010)$, $f_2 (2300)$, $f_2 (2340)$, $\chi c_2 (1P)$, $\chi b_2 (1P)$ and $\chi c_2 (2P)$, the isospinor $K^*_2 (1430)$ and $D^*_2 (2460)$. Experimental data on the branching ratios for $B$ decays involving a tensor meson in the final state provide only upper bounds, as follows [3]:

\[
\mathcal{B}(B^{+(0)} \rightarrow D^*_2 (2460)^{0(-)} \pi^+) < 1.3(2.2) \times 10^{-3},
\]
\[
\mathcal{B}(B^{+(0)} \rightarrow D^*_2 (2460)^{0(-)} \rho^+) < 4.7(4.9) \times 10^{-3},
\]
\[
\mathcal{B}(B^+ \rightarrow K^*_2 (1430)^0 \pi^+) < 6.8 \times 10^{-4},
\]
\[ \mathcal{B}(B^+(0) \to K^*_2(1430)^+(0) \rho^0) < 1.5(1.1) \times 10^{-3}, \]
\[ \mathcal{B}(B^{\pm}(0) \to K^*_2(1430)^{\pm(0)} \phi) < 3.4(1.4) \times 10^{-3}, \]
\[ \mathcal{B}(B^+ \to \pi^+ f_2(1270)) < 2.4 \times 10^{-4}, \]
\[ \mathcal{B}(B^+ \to \rho^0 a_2(1320)^+) < 7.2 \times 10^{-4}, \]
\[ \mathcal{B}(B^0 \to \pi^\pm a_2(1320)^\mp) < 3.0 \times 10^{-4}. \]

(1)

In this work, we analyze two-body charmless hadronic decays of \( B \) mesons to a pseudoscalar meson and a tensor meson in the frameworks of both flavor SU(3) symmetry and generalized factorization. Purely based on the flavor SU(3) symmetry, we first present a model-independent analysis in \( B \to PT \) decays. Then we use the full effective Hamiltonian including all the penguin operators and the ISGW quark model to calculate the branching ratios for \( B \to PT \) decays. Since we include both the tree and the penguin diagram contributions to decay processes, we are able to calculate the branching ratios for all the charmless \( |\Delta S| = 1 \) decays and the relevant CP asymmetries. In order to bridge the flavor SU(3) approach and the factorization approach, we present a set of relations between a flavor SU(3) amplitude and a corresponding amplitude in factorization in \( B \to PT \) decays. Certain ways to test validity of the generalized factorization are proposed by emphasizing interplay between both approaches.

We organize this work as follows. In Sec. II we discuss the notations for SU(3) decomposition and the full effective Hamiltonian for \( B \) decays. In Sec. III we present a model-independent analysis of \( B \to PT \) decays based on SU(3) symmetry. In Sec. IV the two-body decays \( B \to PT \) are analyzed in the framework of generalized factorization. The branching ratios and CP asymmetries are calculated using the form factors obtained in the ISGW quark model. Finally, in Sec. V our results are summarized.

II. FRAMEWORK

In the flavor SU(3) approach, the decay amplitudes of two-body \( B \) decays are decomposed into linear combinations of the SU(3) amplitudes, which are reduced matrix elements defined in Ref. [6]. In SU(3) decomposition of decay amplitudes of the \( B \to PT \) processes, we choose the notations given in Refs. [6] as follows: We represent the decay amplitudes in terms of the basis of quark diagram contributions, \( T \) (tree), \( C \) (color-suppressed tree), \( P \) (QCD-penguin),
S (additional penguin effect involving SU(3)-singlet mesons), E (exchange), A (annihilation), and PA (penguin annihilation). The amplitudes E, A and PA may be neglected to a good approximation because of a suppression factor of $f_B/m_B \approx 5\%$. For later convenience we also denote the electroweak (EW) penguin effects explicitly as $P_{EW}$ (color-favored EW penguin) and $P_{EW}^C$ (color-suppressed EW penguin), even though in terms of quark diagrams the inclusion of these EW penguin effects only leads to the following replacement without introducing new SU(3) amplitudes: $T \rightarrow T + P_{EW}^C$, $C \rightarrow C + P_{EW}$, $P \rightarrow P - \frac{1}{3}P_{EW}^C$, $S \rightarrow S - \frac{1}{3}P_{EW}$. The phase convention used for the pseudoscalar and the tensor mesons is

$$\pi^+(a_2^+) = u\bar{d}, \quad \pi^0(a_0^0) = \frac{1}{\sqrt{2}}(u\bar{u} - d\bar{d}), \quad \pi^-(a_2^-) = -u\bar{d},$$

$$K^+(K_2^+) = u\bar{s}, \quad K^0(K_2^0) = d\bar{s}, \quad \bar{K}^0(\bar{K}_2^0) = \bar{d}s, \quad K^-(K_2^-) = -u\bar{s},$$

$$\eta = -\frac{1}{\sqrt{3}}(u\bar{u} + d\bar{d} - s\bar{s}), \quad \eta' = \frac{1}{\sqrt{6}}(u\bar{u} + d\bar{d} + 2s\bar{s}),$$

$$f_2 = \frac{1}{\sqrt{2}}(u\bar{u} + d\bar{d}) \cos \phi_r + (s\bar{s}) \sin \phi_r, \quad f'_2 = \frac{1}{\sqrt{2}}(u\bar{u} + d\bar{d}) \sin \phi_r - (s\bar{s}) \cos \phi_r, \quad (2)$$

where the mixing angle $\phi_r$ is given by $\phi_r = \arctan(1/\sqrt{2}) - 2\pi^0 \approx 7^\circ$ [10].

In the factorization scheme, we first consider the effective weak Hamiltonian. We then use the generalized factorization approximation to derive hadronic matrix elements by saturating the vacuum state in all possible ways. The method includes color octet non-factorizable contribution by treating $\xi \equiv 1/N_c$ ($N_c$ denotes the effective number of color) as an adjustable parameter. The generalized factorization approximation has been quite successfully used in two-body $D$ decays as well as $B \rightarrow D$ decays [10]. The effective weak Hamiltonian for hadronic $\Delta B = 1$ decays can be written as

$$H_{eff} = \frac{4G_F}{\sqrt{2}} \left[ V_{ub}V_{uq}^*(c_1O_1^u + c_2O_2^u) + V_{cb}V_{cq}^*(c_1O_1^c + c_2O_2^c) - V_{tb}V_{tq}^* \sum_{i=3}^{12} c_iO_i \right]$$

+ H.C., \quad (3)

where $O_i$'s are defined as

$$O_1^f = (\bar{q}\gamma_\mu L f)(\bar{f}\gamma^\mu L b), \quad O_2^f = (\bar{q}_a\gamma_\mu L f_\beta)(\bar{f}_\beta\gamma^\mu L b_\alpha),$$

$$O_{3(5)} = (\bar{q}\gamma_\mu L b)(\Sigma q^\mu R(L)q'), \quad O_{4(6)} = (\bar{q}_a\gamma_\mu L b_\beta)(\Sigma q_\beta^\mu L(R)q_\alpha'),$$

$$O_{7(9)} = \frac{3}{2}(\bar{q}\gamma_\mu L b)(\Sigma e_q q^\gamma R(L)q'), \quad O_{8(10)} = \frac{3}{2}(\bar{q}_a\gamma_\mu L b_\beta)(\Sigma e_{q'} q_\beta^\gamma R(L)q_\alpha'),$$

$$O_{11} = \frac{g_s}{32\pi^2}m_b(\bar{q}\sigma^{\mu\nu}RTa'b)G_{\mu\nu}^a, \quad O_{12} = \frac{e}{32\pi^2}m_b(\bar{q}_a\sigma^{\mu\nu}Rb)F_{\mu\nu}. \quad (4)$$
Here $c_i$’s are the Wilson coefficients (WC’s) evaluated at the renormalization scale $\mu$. And $L(R) = (1 \mp \gamma_5)/2$, $f$ can be $u$ or $c$ quark, $q$ can be $d$ or $s$ quark, and $q'$ is summed over $u$, $d$, $s$, and $c$ quarks. $\alpha$ and $\beta$ are the SU(3) color indices, and $T^a (a = 1, \ldots, 8)$ are the SU(3) generator with the normalization $Tr(T^a T^b) = \delta^{ab}/2$. $g_s$ and $e$ are the strong and electric couplings, respectively. $G^a_{\mu\nu}$ and $F^\mu\nu$ denote the gluonic and photonic field strength tensors, respectively. $O_1$ and $O_2$ are the tree-level and QCD-corrected operators. $O_{3-6}$ are the gluon-induced strong penguin operators. $O_{7-10}$ are the EW penguin operators due to $\gamma$ and $Z$ exchange, and box diagrams at loop level. We shall take into account the chromomagnetic operator $O_{11}$ but neglect the extremely small contribution from $O_{12}$. The dipole contribution is in general quite small, and is of the order of 10% for penguin dominated modes. For all the other modes it can be neglected [1].

We use the ISGW quark model to analyze two-body charmless decay processes $B \to PT$ in the framework of generalized factorization. We describe the parameterizations of the hadronic matrix elements in $B \to PT$ decays: [3]

$$\langle 0 | A^\mu | P \rangle = i f_P p_P^\mu ,$$  

$$\langle T | j^\mu | B \rangle = i h(m_T^2) \epsilon^{\mu\nu\rho\sigma} \epsilon^{*}_\nu p_B^n (p_B + p_T)_\rho (p_B - p_T)_\sigma + k(m_T^2) \epsilon^{*\mu\nu}(p_B)_\nu$$  

$$+ \epsilon^{*}_\alpha \epsilon^{\alpha \beta}_B p_B [b_+(m_T^2)(p_B + p_T)^\mu + b_-(m_T^2)(p_B - p_T)^\mu] ,$$

where $j^\mu = V^\mu - A^\mu$. $V^\mu$ and $A^\mu$ denote a vector and an axial-vector current, respectively. $f_P$ denotes the decay constant of the relevant pseudoscalar meson. $h(m_T^2)$, $k(m_T^2)$, $b_+(m_T^2)$, and $b_-(m_T^2)$ express the form factors for the $B \to T$ transition, $F_{B\to T}(m_T^2)$, which have been calculated at $q^2 = m_T^2$ ($q^\mu \equiv p_B^\mu - p_T^\mu$) in the ISGW quark model [4]. $p_B$ and $p_T$ denote the momentum of the $B$ meson and the tensor meson, respectively. We note that the matrix element

$$\langle 0 | j^\mu | T \rangle = 0 ,$$

because the trace of the polarization tensor $\epsilon^{\mu\nu}$ of the tensor meson $T$ vanishes and the auxiliary condition holds, $p_T^\mu \epsilon_{\mu\nu} = 0$ [1]. Thus, in the generalized factorization scheme, the decay amplitudes for $B \to PT$ can be considerably simplified, compared to those for other two-body charmless decays of $B$ mesons such as $B \to PP$, $PV$, and $VV$: Any decay amplitude for
$B \to PT$ is simply proportional to the decay constant $f_P$ and a certain linear combination of the form factors $F^{B\to T}$, i.e., there is no such amplitude proportional to $f_T \times F^{B\to P}$.

### III. FLAVOR SU(3) ANALYSIS OF $B \to PT$ DECAYS

We list the $B \to PT$ decay modes in terms of the SU(3) amplitudes. The coefficients of the SU(3) amplitudes in $B \to PT$ are listed in Tables I and II for strangeness-conserving ($\Delta S = 0$) and strangeness-changing ($|\Delta S| = 1$) processes, respectively. In the tables, the unprimed and the primed letters denote $\Delta S = 0$ and $|\Delta S| = 1$ processes, respectively. The subscript, $P$ in $T_P, C_P, \ldots$ or $T$ in $T_T, C_T, \ldots$, on each SU(3) amplitude is used to describe such a case that the meson, which includes the spectator quark in the corresponding quark diagram, is the pseudoscalar $P$ or the tensor $T$. Note that the coefficients of the SU(3) amplitudes with the subscript $P$, which would be proportional to $f_T \times F^{B\to P}$, are expressed in square brackets. As explained in Sec. II, the contributions of the SU(3) amplitudes with the subscript $P$ vanish in the framework of factorization, because those contributions contain the matrix element $\langle T|J^{\mu}_{weak}|0 \rangle$ which is zero, see Eq. (1). Thus, it will be interesting to compare the results obtained in the SU(3) analysis with those obtained in the factorization scheme, as we shall see. We will present some ways to test validity of both schemes in future experiment.

Among the $\Delta S = 0$ amplitudes, the tree diagram contribution is expected to be largest so that from Table I the decays $B^+ \to \pi^+ a^0_2, \pi^+ f_2^0,$ and $B^0 \to \pi^+ a^+_2$ are expected to have the largest rates. Here we have noticed that in $B^+ \to \pi^+ f_2^{(0)}$ decays, $\cos \phi_T = 0.99$ and $\sin \phi_T = 0.13$, since the mixing angle $\phi_T \approx 7^0$. The amplitudes for the processes $B \to KK^*_2$ have only penguin diagram contributions, and so they are expected to be small. In principle, the penguin contribution (combined with the smaller color-suppressed EW penguin) $p_T \equiv P_T - \frac{1}{3} P_{EW,T}$ can be measured in $B^{+(0)} \to \bar{K}^0 K^{*+(0)}$. The tree contribution (combined with much smaller color-suppressed EW penguin) $t_T \equiv T_T + P_{EW,T}^C$ are measured by the combination $A(B^{+(0)} \to \bar{K}^0 K^{*+(0)}) - A(B^0 \to \pi^+ a^-_2)$. The amplitudes for $B^0 \to \pi^0 f_2', \eta f_2', \text{ and } \eta' f_2'$ have the color-suppressed tree contributions, $C_T(C_P)$, but are suppressed by $\sin \phi$ so that they are expected to be small. We shall see that these expectations based on the SU(3) approach are consistent with those calculated in the factorization approximation. However, there exist some cases in which the predictions based on both approaches are inconsistent. Note that in
Table I the amplitudes for $B^0 \to \pi^0 a_2^+$ and $B^{+ (0)} \to K^{+ (0)} K^*_{20}$ can be decomposed into linear combinations of the SU(3) amplitudes as follows:

$$A(B^0 \to \pi^- a_2^+) = -T_P - P_P - (2/3)P_{EW,P}^C,$$

$$A(B^+ \to K^0 K^*_{20}) = A(B^0 \to K^0 K^*_{20}) = P_P - (1/3)P_{EW,P}^C.$$ 

As previously explained, in factorization the rates for these processes vanish because all the SU(3) amplitudes are with the subscript $P$. Non-zero of decay rates for these processes would arise from non-factorizable effects or final state interactions. Thus, in principle one can test validity of the factorization ansatz by measuring the rates for these decays in future experiment. Therefore, the non-factorizable penguin contribution, if exists, (combined with the smaller color-suppressed EW penguin) $P_T \equiv P_P - (1/3)P_{EW,P}^C$ can be measured in $B^{+ (0)} \to \bar{K}^{+ (0)} K^*_{20}$. Also, supposing that $P_P$ is very small compared to $T_P$ as usual, one can determine the magnitude of $T_P$ by measuring the rate for $B^0 \to \pi^- a_2^+$. 

In the $|\Delta S| = 1$ decays, the (strong) penguin contribution $P'$ is expected to dominate because of enhancement by the ratio of the CKM elements $|V^*_{tb}V_{ts}|/|V^*_{ub}V_{us}| \approx 50$. We note that the amplitudes for $B^+ \to K^0 a_2^+$ and $B^+ \to \pi^+ K^*_{20}$ have only penguin contributions, respectively, as follows:

$$A(B^+ \to K^0 a_2^+) = P'_T - \frac{1}{3}P_{EW,T}^C,$$

$$A(B^+ \to \pi^+ K^*_{20}) = P'_P - \frac{1}{3}P_{EW,P}^C.$$ 

Thus the penguin contribution (combined with the smaller color-suppressed EW penguin) $P'_T \equiv P'_T - \frac{1}{3}P_{EW,T}^C$ is measured in $B^+ \to K^0 a_2^+$. Similarly, $P'_P \equiv P'_P - \frac{1}{3}P_{EW,P}^C$ is determined in $B^+ \to \pi^+ K^*_{20}$. (In fact, $P'_P = 0$ in factorization.) By comparing the branching ratios for these two modes measured in experiment, one can determine which contribution (i.e., $P'_T$ or $P'_P$) is larger. The (additional penguin) SU(3) singlet amplitude $S'$ is expected to be very small because of the Okubo-Zweig-Iizuka (OZI) suppression, but the SU(3) singlet amplitude $S'$ for the decays involving the pseudoscalar mesons $\eta$ and $\eta'$ is expected not to be very small, since the flavor-singlet couplings of the $\eta$ and $\eta'$ can be affected by the axial anomaly [12]. Thus, from Table II, one can expect that the processes $B^{+ (0)} \to \eta' K^*_{20}$ have large branching ratios compared to other $|\Delta S| = 1$ decays, since they have both of the penguin contributions $P'$. 

7
and $S'$ (and the smaller EW penguin contributions $P'_{EW}$ and $P'_{EW,T}$) and these contributions interfere constructively such as $2P'_T + P'_P + 4S'_T$. In contrast, the processes $B^{+(0)} \to \eta K^{+(0)}_2$ have both of the penguin contributions $P'$ and $S'$, but these interfere destructively such as $-P'_T + P'_P + S'_T$. As in $\Delta S = 0$ decays, there are certain processes whose amplitudes can be expressed by the SU(3) amplitudes, but are expected to vanish in factorization: For instance, $A(B^+ \to \pi^+ K^{*0}_2)$ is given by Eq. (11) and $A(B^0 \to \pi^- K^{*+}_2) = -(T'_P + P'_P + \frac{2}{3}P'_{EW,P})$. Thus, in principle measurement of the rates for these decays can be used to test the factorization ansatz. We also note that the decay amplitudes for modes $B^+ \to \pi^0 K^{*+}_2$ and $B^0 \to \pi^0 K^{*0}_2$ can be respectively written as

\[ A(B^+ \to \pi^0 K^{*+}_2) = -\frac{1}{\sqrt{2}}(T'_P + C'_T + P'_P + P'_{EW,T} + \frac{2}{3}P'_{EW,P}) , \]  

\[ A(B^0 \to \pi^0 K^{*0}_2) = -\frac{1}{\sqrt{2}}(C'_T - P'_P + P'_{EW,T} + \frac{1}{3}P'_{EW,P}) . \]  

Since in factorization only the amplitudes having the subscript $T$ does not vanish, we shall see that $\mathcal{B}(B^+ \to \pi^0 K^{*+}_2) = \mathcal{B}(B^0 \to \pi^0 K^{*0}_2)$ in the factorization scheme, where $\mathcal{B}$ denotes the branching ratio. Thus, if $P'_P$ or $T'_P$ is (not zero and) not very suppressed compared to $C'_T$, then there would be a sizable discrepancy in the relation $\mathcal{B}(B^+ \to \pi^0 K^{*+}_2) = \mathcal{B}(B^0 \to \pi^0 K^{*0}_2)$, and in principle it can be tested in experiment.

From Tables I and II, we find some useful relations among the decay amplitudes. The equivalence relations are

\[ A(B^+ \to K^+ K^*_0) = A(B^0 \to K^0 K^*_0) , \]  

\[ A(B^+ \to K^0 K^*_0) = A(B^0 \to K^0 K^*_0) . \]  

The quadrangle relations are: for the $\Delta S = 0$ processes,

\[ \sqrt{2}A(B^+ \to \eta' a^+_2) + A(B^+ \to \eta a^+_2) = 2A(B^0 \to \eta' a^0_2) + \sqrt{2}A(B^0 \to \eta a^0_2) , \]  

\[ \frac{1}{c}[A(B^+ \to \pi^+ f_2) - \sqrt{2}A(B^0 \to \pi^0 f_2)] = \frac{1}{s}[A(B^+ \to \pi^+ f'_2) - \sqrt{2}A(B^0 \to \pi^0 f'_2)] \]  

\[ = \frac{1}{c}[\sqrt{2}A(B^0 \to \eta' f_2) + A(B^0 \to \eta f_2)] = \frac{1}{s}[\sqrt{2}A(B^0 \to \eta' f'_2) + A(B^0 \to \eta f'_2)] , \]  

and for the $|\Delta S| = 1$ processes,

\[ \sqrt{2}A(B^+ \to K^+ a^0_2) + A(B^+ \to K^0 a^+_2) = A(B^0 \to K^+ a^0_2) + \sqrt{2}A(B^0 \to K^0 a^0_2) , \]
\[
\frac{1}{c}[A(B^+ \to K^+ f_2) - A(B^0 \to K^0 f_2)] = \frac{1}{s}[A(B^+ \to K^+ f'_2) - A(B^0 \to K^0 f'_2)] ,
\]
\[
A(B^+ \to \pi^+ K_2^{*0}) + \sqrt{2} A(B^+ \to \pi^0 K_2^{*+}) = A(B^0 \to \pi^- K_2^{*+}) + \sqrt{2} A(B^0 \to \pi^0 K_2^{*0}) ,
\]
\[
A(B^+ \to \eta K_2^{*+}) + \sqrt{2} A(B^+ \to \eta' K_2^{*+}) = A(B^0 \to \eta K_2^{*0}) + \sqrt{2} A(B^0 \to \eta' K_2^{*0}) ,
\]

(16)

where \(c \equiv \cos \phi_r\) and \(s \equiv \sin \phi_r\). Note that the above relations are derived, purely based on flavor SU(3) symmetry. In the factorization scheme, (neglecting the SU(3) amplitudes with the subscript \(P\)) we would have in addition the approximate relations as follows:[\(^{1}\)]

The following factorization relation would hold:

\[
\sqrt{2} A(B^+ \to \pi^+ a_2^0) \approx A(B^0 \to \pi^+ a_2^-) .
\]

(17)

The quadrangle relations given in Eqs. \(^{(15, 16)}\) would be divided into the following factorization relations; for the \(|\Delta S| = 0\) processes,

\[
A(B^+ \to \eta a_2^+) \approx \sqrt{2} A(B^0 \to \eta a_2^0) ,
\]

\[
\approx -\sqrt{2} A(B^+ \to \eta' a_2^+) \approx -2 A(B^0 \to \eta' a_2^0) ,
\]

\[
\frac{1}{c} A(B^{+(0)} \to \pi^{+(0)} f_2) \approx \frac{1}{s} A(B^{+(0)} \to \pi^{+(0)} f'_2) ,
\]

\[
\frac{1}{c} A(B^0 \to \eta f_2) \approx \frac{1}{s} A(B^0 \to \eta f'_2)
\]

\[
\approx -\frac{1}{c} \sqrt{2} A(B^0 \to \eta' f_2) \approx -\frac{1}{s} \sqrt{2} A(B^0 \to \eta' f'_2) ,
\]

(18)

and for the \(|\Delta S| = 1\) processes,

\[
\sqrt{2} A(B^+ \to K^+ a_2^0) \approx A(B^0 \to K^+ a_2^-) ,
\]

\[
A(B^+ \to K^0 a_2^+) \approx \sqrt{2} A(B^0 \to K^0 a_2^0) ,
\]

\[
\frac{1}{c} A(B^+ \to K^+ f_2) \approx \frac{1}{s} A(B^+ \to K^+ f'_2) ,
\]

\[
\frac{1}{c} A(B^0 \to K^0 f_2) \approx \frac{1}{s} A(B^0 \to K^0 f'_2) ,
\]

\[
A(B^+ \to \pi^0 K_2^{*+}) \approx A(B^0 \to \pi^0 K_2^{*0}) ,
\]

\[
A(B^+ \to \eta K_2^{*+}) \approx A(B^0 \to \eta K_2^{*0}) ,
\]

\[
A(B^+ \to \eta' K_2^{*+}) \approx A(B^0 \to \eta' K_2^{*0}) .
\]

(19)

\(^{1}\)Considering SU(3) breaking effects, we use the symbol \(\approx\) in the following relations instead of the equivalence symbol \(=\).
Therefore, in principle the above relations given in Eqs. \([7, 8, 9]\) provide an interesting way to test the factorization scheme by measuring and comparing magnitudes of the decay amplitudes involved in the relations. In consideration of SU(3) breaking effects, the relation in Eq. \([7]\) is best to use, because in fact the relation arises from isospin symmetry assuming \(C_P = P_P = P_{EW,P} = P_{EW,P}^C = 0\). (However, if \(C_P\) is negligibly small (though not zero) compared to \(T_T\), Eq. \([7]\) will approximately hold.)

### IV. ANALYSIS OF \(B \to PT\) DECAYS USING THE ISGUR-SCORA-GRINSTEIN-WISE MODEL

Now, we present expressions for SU(3) amplitudes involved in \(B \to PT\) decays as calculated in the factorization scheme as follows \([13]\). (Note that all the SU(3) amplitudes with the subscript \(P\) vanish because those are proportional to the matrix element \(\langle T|j^\mu|0\rangle\).)

\[
T_T^{(i)} = i\frac{G_F}{\sqrt{2}}V_{ub}V_{ud}(s)\left(f_P\epsilon^{*}\nu_P\beta_B\beta_B F^{B\to T}(m_P^2)\right)a_1 ,
\]

\[
C_T^{(i)} = i\frac{G_F}{\sqrt{2}}V_{ub}V_{ud}(s)\left(f_P\epsilon^{*}\nu_P\beta_B\beta_B F^{B\to T}(m_P^2)\right)a_2 ,
\]

\[
S_T^{(i)} = -i\frac{G_F}{\sqrt{2}}V_{tb}V_{td}(s)\left(f_P\epsilon^{*}\nu_P\beta_B\beta_B F^{B\to T}(m_P^2)\right)(a_3 - a_5) ,
\]

\[
P_T^{(i)} = -i\frac{G_F}{\sqrt{2}}V_{tb}V_{td}(s)\left(f_P\epsilon^{*}\nu_P\beta_B\beta_B F^{B\to T}(m_P^2)\right)(a_4 - 2a_6 X_{qq'}) ,
\]

\[
P_{EW,T}^{(i)} = -i\frac{G_F}{\sqrt{2}}V_{tb}V_{td}(s)\left(f_P\epsilon^{*}\nu_P\beta_B\beta_B F^{B\to T}(m_P^2)\right)\frac{3}{2}(a_7 - a_9) ,
\]

\[
P_{EW,T}^{C(i)} = -i\frac{G_F}{\sqrt{2}}V_{tb}V_{td}(s)\left(f_P\epsilon^{*}\nu_P\beta_B\beta_B F^{B\to T}(m_P^2)\right)\frac{3}{2}(a_{10} - 2a_8 X_{qq'}) ,
\]

where

\[
F^{B\to T}(m_P^2) = k(m_P^2) + (m_B^2 - m_T^2)b_+(m_P^2) + m_B^2b_-(m_P^2) , \tag{21}
\]

\[
X_{qq'} = \frac{m_P^2}{(m_b + m_q)(m_q + m_q)} . \tag{22}
\]

Here the effective coefficients \(a_i\) are defined as \(a_i = c_i^{eff} + \xi c_i^{eff} (i = \text{odd})\) and \(a_i = c_i^{eff} + \xi c_i^{eff} (i = \text{even})\) with the effective WC’s \(c_i^{eff}\) at the scale \(m_b\) \([11]\), and by treating \(\xi \equiv 1/N_c\) (\(N_c\) denotes the effective number of color) as an adjustable parameter. The last term with \(b_\cdot\) in Eq. \([21]\) gives a negligible contribution to the decay amplitude due to the small mass factor.
With Tables I, II and the above relations (20), one can easily write down in the factorization
scheme the amplitude of any \( B \to PT \) mode shown in the tables. For example, from Table I
and the relations (20), the amplitude of the process \( B^+ \to \pi^+ a_0^0 \) can be written as
\[
A(B^+ \to \pi^+ a_0^0) = -\frac{1}{\sqrt{2}} \left( T_T + C_P + P_T - P_P + P_{EW,P} + \frac{2}{3} P_{EW,T} + \frac{1}{3} P_{EW,P}^C \right) 
\]
\[
= i \frac{G_F}{2} f_\pi^* p_B^\mu p_B^\nu F_B^\rightarrow a_0^0 \left( m_\pi^2 \right) \{ V_{ub}^* V_{ud} a_1 - V_{tb}^* V_{td} [a_4 + a_{10} - 2(a_6 + a_8) X_{da}] \} . \tag{23}
\]
Here we have used the fact that \( C_P, P_P, P_{EW,P}, \) and \( P_{EW,P}^C \) with the subscript \( P \) all vanish. In
Appendix, expressions for all the amplitudes of \( B \to PT \) decays are presented as calculated in the
factorization scheme.

To calculate the unpolarized decay rates for \( B \to PT \), we sum over polarizations of the
tensor meson \( T \) using the following formula [2]:
\[
\sum_\lambda \epsilon_{\alpha\beta}(p_T, \lambda) \epsilon'^*_{\mu\nu}(p_T, \lambda) = \frac{1}{2}(\theta_{\alpha\mu}\theta_{\beta\nu} + \theta_{\beta\mu}\theta_{\alpha\nu}) - \frac{1}{3}\theta_{\alpha\beta}\theta_{\mu\nu} , \tag{24}
\]
where \( \theta_{\alpha\beta} = -g_{\alpha\beta} + (p_T)_\alpha (p_T)_\beta / m_T^2 \). Then, the decay rate for \( B \to PT \) is given by
\[
\Gamma(B \to PT) = \frac{|\vec{p}_p|^5}{12\pi m_T^2} \left( \frac{m_B}{m_T} \right)^2 \left| \frac{A(B \to PT)}{\epsilon'^*_{\mu\nu} p_B^\mu p_B^\nu} \right|^2 , \tag{25}
\]
where \( |\vec{p}_p| \) is the magnitude of three-momentum of the final state particle \( P \) or \( T \) \((|\vec{p}_p| = |\vec{p}_T|)\)
in the rest frame of the \( B \) meson. The CP asymmetry, \( A_{CP} \), is defined by
\[
A_{CP} = \frac{B(b \to f) - B(\bar{b} \to \bar{f})}{B(b \to f) + B(\bar{b} \to \bar{f})} , \tag{26}
\]
where \( b \) and \( f \) denote \( b \) quark and a generic final state, respectively.

We calculate the branching ratios and CP asymmetries for \( B \to PT \) decay modes for various
input parameter values. The predictions are sensitive to several input parameters such as the
form factors, the strange quark mass, the parameter \( \xi \equiv 1/N_c \), the CKM matrix elements and
in particular, the weak phase \( \gamma \). In a recent work [11] on charmless \( B \) decays to two light
mesons such as \( PP \) and \( VP \), it has been shown that the favored values of the input parameters are
\[
\xi \approx 0.45, \ m_s(m_b) \approx 85 \ MeV, \ \gamma \approx 110^0, \ V_{cb} = 0.040, \ \text{and} \ \ |V_{ub}/V_{cb}| = 0.087
\]

\[\text{In the factorization scheme, we use the usual phase convention for the pseudoscalar and the tensor mesons as follows: } \pi^0(a_2^0) = \frac{1}{\sqrt{2}}(u\bar{u} - d\bar{d}), \ \pi^-(a_2^-) = \bar{u}d, \ K^-(K^*^-) = \bar{u}s. \]
in order to get the best fit to the recent experimental data from the CLEO collaboration. For our numerical calculations, we use the following values of the decay constants (in MeV units) [10,14,15]:

\[ f_\pi = 132, \quad f_\eta = 131, \quad f_\eta' = 118, \quad f_K = 162. \]

We use the values of the form factors for the \( B \to T \) transition calculated in the ISGW model [4]. The strange quark mass \( m_s \) is in considerable doubt: \( i.e., \) QCD sum rules give \( m_s(1 \text{ GeV}) = (175 \pm 25) \) MeV and lattice gauge theory gives \( m_s(2 \text{ GeV}) = (100 \pm 20 \pm 10) \) MeV in the quenched lattice calculation [14]. In this analysis we use two representative values of \( m_s = 100 \) MeV and \( m_s = 85 \) MeV at \( m_b \) scale. Current best estimates for CKM matrix elements are \( V_{cb} = 0.0381 \pm 0.0021 \) and \( |V_{ub}/V_{cb}| = 0.085 \pm 0.019 \) [17]. We use \( V_{cb} = 0.040 \) and \( |V_{ub}/V_{cb}| = 0.087 \). It has been known that there exists the discrepancy in values of \( \gamma \) extracted from CKM-fitting at \( \rho - \eta \) plane [18] and from the \( \chi^2 \) analysis of non-leptonic decays of \( B \) mesons [13,20]. The value of \( \gamma \) obtained from unitarity triangle fitting is in the range of \( 60^0 \sim 80^0 \). But in analysis of non-leptonic \( B \) decay, possibility of larger \( \gamma \) has been discussed by Deshpande et al. [19] and He et al. [20]. The obtained value of \( \gamma \) is \( \gamma = 90^0 \sim 140^0 \). In our calculations we use two representative values of \( \gamma = 110^0 \) and \( \gamma = 65^0 \).

In Tables III – VI, we show the branching ratios and the CP asymmetries for \( B \to PT \) decays with either \( \Delta S = 0 \) or \( |\Delta S| = 1 \). In the tables the second and the third columns correspond to the sets of the input parameters,

\[ \{ \xi = 0.1, \ m_s = 85 \text{ MeV}, \ \gamma = 110^0 \} \quad \text{and} \quad \{ \xi = 0.1, \ m_s = 100 \text{ MeV}, \ \gamma = 65^0 \}, \]

respectively. Similarly, the fourth and the fifth columns correspond to the cases,

\[ \{ \xi = 0.3, \ m_s = 85 \text{ MeV}, \ \gamma = 110^0 \} \quad \text{and} \quad \{ \xi = 0.3, \ m_s = 100 \text{ MeV}, \ \gamma = 65^0 \}, \]

respectively. The sixth and the seventh columns correspond to the cases,

\[ \{ \xi = 0.5, \ m_s = 85 \text{ MeV}, \ \gamma = 110^0 \} \quad \text{and} \quad \{ \xi = 0.5, \ m_s = 100 \text{ MeV}, \ \gamma = 65^0 \}, \]

respectively. Here \( \xi \equiv 1/N_c = 0.3 \) corresponds to the case of naive factorization \( (N_c = 3) \). It has been known that in \( B \to D \) decays the generalized factorization has been successfully used with the favored value of \( \xi \approx 0.5 \) [21]. Also, as mentioned above, a recent analysis of charmless
$B$ decays to two light mesons such as $PP$ and $VP$ [11] shows that $\xi \approx 0.45$ is favored with certain values of other parameters for the best fit to the recent CLEO data.

The branching ratios and the CP asymmetries for $B \to PT$ decay modes with $\Delta S = 0$ are shown in Table III and IV. Among $\Delta S = 0$ modes, the decay modes $B^+ \to \pi^+ a_2^0$, $B^+ \to \pi^+ f_2$, and $B^0 \to \pi^+ a_2^-$ have relatively large branching ratios of a few times $10^{-7}$. This prediction is consistent with that based on flavor SU(3) symmetry. We see that in the factorization scheme the following equality between the branching ratios holds for any set of the parameters given above: $2B(B^+ \to \pi^+ a_2^0) \approx B(B^0 \to \pi^+ a_2^-)$, as discussed in Eq. (17). (Little deviation from the exact equality arises from breaking of isospin symmetry.) We also see from Table III that $B(B^+ \to \pi^0 a_2^+)$ is much smaller than $B(B^+ \to \pi^+ a_2^0)$ by an order of magnitude or even three orders of magnitude depending on values of the input parameters, because in factorization the dominant contribution to the former mode arises from the color-suppressed tree diagram ($C_T$), while the dominant one to the latter mode arises from the color-favored tree diagram ($T_T$). Note that in flavor SU(3) symmetry the amplitude for $B^+ \to \pi^+ a_2^0$ has the color-favored tree contribution $T_P$ constructive to the color-suppressed tree contribution $C_T$ (in addition to small contributions from the penguin diagrams). (Also recall that the magnitude of $T_P$ can be possibly measured by Eq. (8)). In case that $T_P$ is not small compared to $T_T$, $B(B^+ \to \pi^0 a_2^+)$ can be comparable to $B(B^+ \to \pi^+ a_2^0)$. Therefore, measurement of the modes $B \to \pi a_2$ in future experiment will provide important information on the above discussion. Some $\Delta S = 0$ processes such as $B^+ \to \eta' a_2^+$, $B^0 \to \eta' a_2^0$, and $B^0 \to \eta' f_2$ have the branching ratios of order of $10^{-7}$. The branching ratios of the other processes are order of $10^{-8}$ or less. The CP asymmetry for $B^+ \to \eta' a_2^+$ is relatively large (about 20% or larger) with the branching ratio of order of $10^{-7}$ for $\xi = 0.5$ and 0.1. The CP asymmetry for $B^+ \to \eta a_2^+$, $B^0 \to \eta a_2^0$, $\eta f_2$ can be as large as 71% for $\xi = 0.5$, with the branching ratios of $O(10^{-8})$.

Tables V shows the branching ratios for $|\Delta S| = 1$ decay processes. In $|\Delta S| = 1$ decays, the relevant penguin diagrams give dominant contribution to the decay rates. We see that the branching ratios for $|\Delta S| = 1$ decays are in range between $O(10^{-7})$ and $O(10^{-10})$, similar to those for $\Delta S = 0$ decays. The modes $B^{+\,(0)} \to \eta' K_2^{*+\,(0)}$ have relatively larger branching ratios of $O(10^{-7})$. In contrast, the modes $B^{+\,(0)} \to \eta K_2^{*+\,(0)}$ have very small branching ratios of $O(10^{-9})$ to $O(10^{-10})$. Based on flavor SU(3) symmetry, this fact has been expected by observation
that the penguin contributions $P'$ and $S'$ interfere constructively for $B^{+(0)} \rightarrow \eta' K_2^{*(0)}$, but destructively for $B^{+(0)} \rightarrow \eta K_2^{*(0)}$. From Eq. (20), we see that $P'_T$ and $S'_T$ are proportional to $(a_4 - 2a_6 X_{ss})$ and $(a_3 - a_5)$, respectively, in addition to other common factors. Indeed, in the factorization scheme, since $(a_4 - 2a_6 X_{ss})$ and $(a_3 - a_5)$ have the same sign (all positive), the combination $(2P'_T + 4S'_T)$ appearing in $B^{+(0)} \rightarrow \eta' K_2^{*(0)}$ causes constructive interference, while the combination $(-P'_T + S'_T)$ appearing in $B^{+(0)} \rightarrow \eta K_2^{*(0)}$ causes destructive interference (see Appendix). Thus the prediction for these decay modes are consistent in both approaches. The modes $B^+ \rightarrow \pi^0 K_2^{*+}$ and $B^0 \rightarrow \pi^0 K_2^{*0}$ have almost the same branching ratios of $O(10^{-8})$ in the factorization scheme (also see Appendix). In flavor SU(3) symmetry, as shown in Table II, the decay amplitudes for these modes have the contributions from $P'_P$ or $T'_P$. Thus, as discussed in the previous section, if $P'_P$ or $T'_P$ is not very suppressed compared to $C'_T$, then there would be a sizable discrepancy in $\mathcal{B}(B^+ \rightarrow \pi^0 K_2^{*+}) \approx \mathcal{B}(B^0 \rightarrow \pi^0 K_2^{*0})$, and in principle it can be tested in experiment. The terms $-(T'_P + P'_P + \frac{2}{3}P_{EW,P}^{C_T'})$ and $P'_P - \frac{1}{3}P_{EW,P}^{C_T'}$ can be determined by measuring the branching ratios for $B^0 \rightarrow \pi^- K_2^{*+}$ and $B^+ \rightarrow \pi^+ K_2^{*0}$, respectively. The CP asymmetries $A_{CP}$ in $|\Delta S| = 1$ decays are shown in Table VI. $A_{CP}$’s in most modes are expected to be quite small. In $B^{+(0)} \rightarrow \eta K_2^{*(0)}$, $A_{CP}$ can be as large as 92%, but the corresponding branching ratio is as small as about $O(10^{-9})$.

V. CONCLUSION

We have analyzed exclusive charmless decays $B \rightarrow PT$ in the schemes of both flavor SU(3) symmetry and generalized factorization. Using the flavor SU(3) symmetry, we have decomposed all the amplitudes for decays $B \rightarrow PT$ into linear combinations of the relevant SU(3) amplitudes. Based on the decomposition, we have shown that certain decay modes, such as $B^+ \rightarrow \pi^+ a_2^0$, $\pi^+ f_2$ and $B^0 \rightarrow \pi^+ a_2^-$ in $\Delta S = 0$ decays, and $B^{+(0)} \rightarrow \eta' K_2^{*(0)}$ in $|\Delta S| = 1$ decays, are expected to have the largest decay rates and so these modes can be preferable to find in future experiment. Certain ways to test validity of the factorization scheme have been presented by emphasizing interplay between both approaches and carefully combining the predictions from both approaches. In order to bridge the flavor SU(3) approach and the factorization approach, we have explicitly presented a set of relations between a flavor SU(3) amplitude and a corresponding amplitude in factorization in $B \rightarrow PT$ decays.
To calculate the branching ratios for $B \to PT$ decays, we have used the full effective Hamiltonian including all the penguin operators which are essential to analyze the $|\Delta S| = 1$ processes and to calculate CP asymmetries. We have also used the non-relativistic quark model proposed by Isgur, Scora, Grinstein, and Wise to obtain the form factors describing $B \to T$ transitions. As shown in Tables III and V, the branching ratios vary from $O(10^{-7})$ to $O(10^{-10})$. Consistent with the prediction from the flavor SU(3) analysis, the decay modes such as $B^+ \to \pi^+ a_2^0$, $\pi^+ f_2$, $B^0 \to \pi^+ a_2^-$ and $B^{+(0)} \to \eta' K^{*(0)}_2$ as well as $B^+ \to \eta' a_2^+$ have the branching ratios of order of $10^{-7}$. In particular, the branching ratio for the mode $B^0 \to \pi^+ a_2^-$ can be as large as almost $O(10^{-6})$. We have identified the decay modes where the CP asymmetries are expected to be large, such as $B \to \eta' a_2^+$, $\eta a_2^0$, $\eta f_2$ in $\Delta S = 0$ decays, and $B^{+(0)} \to \eta K^{*+}(0)$ in $|\Delta S| = 1$ decays. Due to possible uncertainties in the hadronic form factors of $B \to PT$ and non-factorization effects, the predicted branching ratios could be increased by even two orders of magnitude for some decay modes [22]. Although experimentally challenging, the exclusive charmless decays, $B \to PT$, can probably be carried out in details at hadronic $B$ experiments such as BTeV and LHC-B, where more than $10^{10}$ $B$-mesons will be produced per year, as well as at present asymmetric $B$ factories of Belle and Babar.

**APPENDIX**

In this Appendix, we present expressions for all the decay amplitudes of $B \rightarrow PT$ modes shown in Tables I and II as calculated in the factorization scheme. Below we use $F_{B \rightarrow T}$ and $X_{a_2}$ defined in Eqs. (21) and (22).

(1) $B \rightarrow PT$ ($\Delta S = 0$) decays.

\[
A(B^+ \rightarrow \pi^+ a_2^0) = i \frac{G_F}{2} f_\pi \epsilon^{\mu \nu \rho} \epsilon^\nu_{\mu B} F^{B \rightarrow a_2^0}(m_\pi^2) \left\{ V_{ub} V_{ud} a_1 - V_{tb} V_{td} [a_4 + a_10 - 2(a_6 + a_8) X_{ud}] \right\},
\]

\[
A(B^+ \rightarrow \pi^+ f_2) = i \frac{G_F}{2} \cos \phi_T f_\pi \epsilon^{\mu \nu \rho} \epsilon^\nu_{\mu B} F^{B \rightarrow f_2}(m_\pi^2) \left\{ V_{ub} V_{ud} a_1 - V_{tb} V_{td} [a_4 + a_10 - 2(a_6 + a_8) X_{ud}] \right\}
\]

\[
A(B^+ \rightarrow \pi^+ f_2') = i \frac{G_F}{2} \sin \phi_T f_\pi \epsilon^{\mu \nu \rho} \epsilon^\nu_{\mu B} F^{B \rightarrow f_2}(m_\pi^2) \left\{ V_{ub} V_{ud} a_1 - V_{tb} V_{td} [a_4 + a_10 - 2(a_6 + a_8) X_{ud}] \right\}
\]

(2) $B^0 \rightarrow \pi^0 a_2^0$ decays.

\[
A(B^0 \rightarrow \pi^0 a_2^0) = i \frac{G_F}{2} f_\pi \epsilon^{\mu \nu \rho} \epsilon^\nu_{\mu B} F^{B \rightarrow a_2^0,(m_\pi^2)} \left\{ V_{ub} V_{ud} a_2 - V_{tb} V_{td} [a_4 + a_10 - 2(a_6 + a_8) X_{ud}] \right\}
\]

\[
A(B^0 \rightarrow \pi^0 f_2) = i \frac{G_F}{2} \cos \phi_T f_\pi \epsilon^{\mu \nu \rho} \epsilon^\nu_{\mu B} F^{B \rightarrow f_2}(m_\pi^2) \left\{ V_{ub} V_{ud} a_2 - V_{tb} V_{td} [a_4 + a_10 - 2(a_6 + a_8) X_{ud}] \right\}
\]

\[
A(B^0 \rightarrow \pi^0 f_2') = i \frac{G_F}{2} \sin \phi_T f_\pi \epsilon^{\mu \nu \rho} \epsilon^\nu_{\mu B} F^{B \rightarrow f_2}(m_\pi^2) \left\{ V_{ub} V_{ud} a_2 - V_{tb} V_{td} [a_4 + a_10 - 2(a_6 + a_8) X_{ud}] \right\}
\]
\[ A(B^0 \to \eta_0^0) = \frac{i G_F}{\sqrt{2}} \frac{1}{\sqrt{6}} f_{\eta_0} \varepsilon_{\mu \nu} P_{\mu} P_{\nu} F^{B \to a_0^0} (m_{\eta_0}^2) \{ V_{ub}^* V_{ud} a_2 \} \]
\[ - V_{tb}^* V_{td} \left[ a_3 + a_4 - a_5 + a_7 - a_9 - \frac{1}{2} a_{10} - 2 \left( a_6 - \frac{1}{2} a_8 \right) X_{dd} \right] \]
\[ A(B^0 \to \eta f_2) = \frac{i G_F}{\sqrt{2}} \frac{1}{\sqrt{6}} \cos \phi_T f_{\eta} \varepsilon_{\mu \nu} P_{\mu} P_{\nu} F^{B \to f_2} (m_{\eta}^2) \{ V_{ub}^* V_{ud} a_2 \}
\[ - V_{tb}^* V_{td} \left[ a_3 + a_4 - a_5 + a_7 - a_9 - \frac{1}{2} a_{10} - 2 \left( a_6 - \frac{1}{2} a_8 \right) X_{dd} \right] \]

(58)
TABLES

TABLE I. Coefficients of SU(3) amplitudes in $B \to PT (\Delta S = 0)$. The coefficients of the SU(3) amplitudes with the subscript $P$ are expressed in square brackets. As explained in Sec. II, the contributions of the SU(3) amplitudes with the subscript $P$ vanish in the framework of factorization, because those contributions contain the matrix element $\langle \pi|J_{\mu}^{\text{weak}}|0 \rangle$, which is zero. Here $c$ and $s$ denote $\cos \phi_p$ and $\sin \phi_p$, respectively.

TABLE III. The branching ratios for $B \to PT$ decay modes with $\Delta S = 0$. The second and the third columns correspond to the cases of sets of the parameters: $\{\xi = 0.1, m_s = 85$ MeV, $\gamma = 110^0\}$ and $\{\xi = 0.1, m_s = 100$ MeV, $\gamma = 65^0\}$, respectively. Similarly, the fourth and the fifth columns correspond to the cases: $\{\xi = 0.3, m_s = 85$ MeV, $\gamma = 110^0\}$ and $\{\xi = 0.3, m_s = 100$ MeV, $\gamma = 65^0\}$, respectively. The sixth and the seventh columns correspond to the cases: $\{\xi = 0.5, m_s = 85$ MeV, $\gamma = 110^0\}$ and $\{\xi = 0.5, m_s = 100$ MeV, $\gamma = 65^0\}$, respectively.
