Abstract This work describes the synthesis of piperazine hydrochloride in multigram scale and high yields with promising industrial applications. This methodology is simple, fast, safe, low cost, and applicable to the synthesis of a wide variety of piperazine derivatives, being very useful in medicinal chemistry and other fields.

Keywords piperazine, medicinal chemistry, chloridrate, alkylation and acylation, green chemistry

Introduction
Piperazine (1,4-hexahydropyrazine) is a 6-member heterocyclic ring, which contains two nitrogen atoms in its structure. This class of compounds was already known to be special in the early 1950’s when piperazine was used as an anthelmintic drug. Nowadays, due to their potency and biological properties, piperazine and its derivatives still have a tremendous impact on the development of new drugs.[1] The piperazine nucleus can be found in several classes of drugs and bioactive compounds with a wide range of biological activities, such as anti-malarial, anti-tuberculosis, antibacterial, antitumor, anti-inflammatory, anti-allergic, anti-schizophrenia, anti-psychotic, anti-hypertensive, anti-tussive, anti-influenza, antiretroviral, among others.[2-6] Some examples of commercially available drugs bearing the piperazine moiety are shown in Figure 1.

![Figure 1 Piperazine scaffold: a remarkable tool in the generation of diverse pharmacological agents.](image)

One major problem of piperazine chemistry is the di-alkylation or di-acylation of the piperazine core.[7-10] This can be solved in an elegant way by using a procedure based on the synthesis of piperazine hydrochloride in situ, from one mole of piperazine and one mole of piperazine dihydrochloride, blocking one of the nitrogens and leading to easy synthesis of mono-alkylated or mono-acylated piperazine derivatives (Scheme 1).[11] Therefore, the aim of this paper is to report an easy, clean and fast multigram scale synthesis to obtain piperazine monochloridrate in large scale, which can be used as a building block to synthesize a wide variety of piperazine derivatives such as N-methylpiperazine.

It is noteworthy that this procedure is very useful in medicinal chemistry and other fields with promising industrial applications.

Results and Discussion
Piperazine dihydrochloride was obtained by the addition of aqueous hydrochloric acid (37%) to an ethanolic solution of piperazine under vigorous stirring until the equivalence point of the titration was reached and pH dropped to 1 (160 mL of HCl, Figure 2). The precipitate formed, a white solid, was filtered, washed with cool ethanol and dried under vacuum. It should be noted that this compound is usually synthesized by passing a stream of HCl(g) through the solution.[11]

![Figure 2 pH variation observed with an universal pH indicator (Merck) during HCl addition.](image)
Piperazine hydrochloride was obtained by the reaction of piperazine dihydrochloride and piperazine in ethanol under reflux (Scheme 2). After cooling of the solution, the formation of white crystals was observed. The precipitate was filtered, washed with cold ethanol and allowed to dry under vacuum.

Both products and piperazine were analyzed by $^1$H NMR and $^{13}$C NMR (400.00 MHz and 100.00 MHz, respectively, in D$_2$O with DSS as the internal standard). The $^1$H NMR spectral data shows the deshielding of the hydrogens when comparing piperazine (δ 2.74), to piperazine hydrochloride (δ 3.11) and piperazine dihydrochloride (δ 3.59), while the $^{13}$C NMR displays the shielding of the carbons from piperazine to piperazine hydrochloride and piperazine dihydrochloride (δ 47.5, 45.3 and 43.1, respectively). The synthesized compounds were also submitted to thermal analyses carried out using thermogravimetric technique (TG) that provided useful data for thermal stability of the salts. Piperazine dihydrochloride showed an estimated mass loss of 13.90% within the temperature range 25—190 º C, which may be attributed to the loss of water. In the case of piperazine hydrochloride, an estimated mass loss of 5.08% within the temperature range 25—140 º C was observed and may be attributed to the loss of volatile solvents.

Furthermore, in order to assess usability of the isolated piperazine hydrochloride in a chemical reaction, we synthesized 1-benzylpiperazine through in situ formation of piperazine hydrochloride (Scheme 3, Eq. 1) and direct synthesis (Scheme 3, Eq. II). It is noteworthy that direct synthesis from stock piperazine hydrochloride displayed similar results when compared to the classic methodology, and the desired product was afforded with 85% and 81% yields, respectively. In both cases, excess piperazine was recovered as piperazine dihydrochloride (97% yield) by filtration of the ethanolic solution. Ethanol was removed under reduced pressure and 1-benzylpiperazine hydrochloride retrieved from the crude oil after resolubilization in water and washing with ethyl acetate.

\]

**Experimental**

**Instruments**

NMR spectra were analyzed using a 400 MHz Bruker AC spectrometer with deuterated water as the solvent and DSS as the internal standard. Infrared spectra were obtained using a Thermo Nicolet 6700 spectrometer and the Thermogravimetric Analysis were recorded from a Mettler Toledo TGA/SDTA 851e.

**General procedure**

**Piperazine dihydrochloride:** A 3 L round-bottomed flask equipped with a mechanical stirrer was charged with 86.14 g (1 mol) of piperazine and 250 mL of ethanol, in ambient temperature under stirring until total solubilization.

Hydrochloric acid 37% was then added slowly with an addition funnel, until pH 1 was reached (160 mL). After the addition, the internal temperature did not exceed 50 º C. The white precipitate obtained was filtered by suction on a glass Buchner funnel with sintered porous plate and washed with 100 mL of cool ethanol (0 º C), and then transferred to a to a tared 1 L, round-bottomed flask and dried at 0.01 mbar in high vacuum system for 16 h (154.01 g; 97%) (Figure 3). $^1$H NMR (400 MHz, D$_2$O) δ: 3.61 (8H, s, CH$_2$), $^{13}$C NMR (100 MHz, D$_2$O) δ: 40.31 (CH$_3$). IR $\nu_{\text{max}}$: 3471, 2915, 2780 cm$^{-1}$.

**Figure 3** Piperazine dihydrochloride after filtration.

**Piperazine hydrochloride:** To a 1 L, two-necked, round-bottomed flask equipped with a mechanical stirrer was added 79.57 g (0.5 mol) of piperazine dihydrochloride and 500 mL of ethanol under stirring and reflux until total solubilization. Then, 43.07 g (0.5 mol) piperazine was added slowly until total solubilization. The solution was cooled and the formation of a white precipitate was observed. The precipitate was filtered by suction on a glass Buchner funnel with sintered porous plate and washed with 200 mL of cool ethanol (0 º C) (Figure 4), and then transferred to a tared 1 L, round-bottomed flask and dried at 0.01 mbar in high vacuum system for 16 h (117.25 g; 96%). $^1$H NMR (400 MHz, D$_2$O) δ: 3.13 (8H, s, CH$_2$), $^{13}$C NMR (100 MHz, D$_2$O) δ: 42.53 (CH$_3$). IR $\nu_{\text{max}}$: 3415, 3382, 3243, 2973, 2834 cm$^{-1}$.

**Figure 4** Precipitate formed after cooling.

**Benzylpiperazine (through in situ formation of piperazine hydrochloride):** Piperazine (25 mmol), piperazine dihydrochloride (25 mmol), and ethanol (50 mL) were added to a round-bottom flask (100 mL) under heavy stirring and reflux.
Preparation of Piperazine Hydrochloride

Benzylpiperazine (from stock piperazine hydrochloride): piperazine hydrochloride (50 mmol), 25 mmol of the benzyl chloride, and ethanol (50 mL) were added to a round-bottom flask (100 mL), and kept under reflux, and stirring for 2 h. Benzylpiperazine dichloridrate was removed by filtration and the solvent was removed, resulting in the crude product, which was solubilized in water and purified by extraction with ethyl acetate (3 × 20 mL). The desired benzylpiperazine was obtained as hydrochlorides after the evaporation of the aqueous layer.

Conclusions

We have developed a simple, fast, safe, and low cost multigram scale methodology for the synthesis of piperazine hydrochloride with promising industrial applications. It is important to mention that this product is stable and can be stock, so large-scale pre-production of piperazine hydrochloride ends up being an interesting optimization to the original procedure, since the in situ equilibrium may take hours to be reached. Therefore, this procedure will be very useful to both synthetic and medicinal chemistry.
