INTRODUCTION

Overweight and obesity are rapidly becoming a major global public health problem ("globesity")\(^1\)\(^-\)\(^3\). Although the perception of obesity has improved, and the treatment of obesity has increased, global obesity rates are still on the rise\(^4\)\(^-\)\(^6\). A survey found that one-third of university students in Spain was either overweight or obese\(^7\). The relative prevalence of obesity in Asian populations is lower than in other parts of the world, according to the World Health Organization\(^8\). However, the prevalence of obesity is increas-
SLEEP QUALITY IS INVERSELY RELATED TO BODY MASS INDEX AMONG UNIVERSITY STUDENTS

METHODS
Participants

A random multistage cluster sampling method was used to select the study population from six universities in the southern Anhui region, China, from December 2014 to February 2015. We selected university students from different programs to represent college students and used a questionnaire survey in classes. Trained investigators administered the questionnaire survey to 1400 students and measured relevant indicators. Seventy-two participants were excluded because of missing information, and 1328 participants aged 19–23 years remained in the present analysis (470 males and 858 females). All participants agreed to provide their personal information regarding the purpose and the procedures of our study, and written informed consent was obtained.

BMI
Weight and height were self-reported by the students. The BMI was computed using a standard equation (BMI = weight in kg/height squared in meters), according to the Working Group on Obesity in China. Body type was categorized as follows: underweight (BMI<18.5); normal (18.5<BMI<23.9); overweight (24.0<BMI<27.9); and obese (BMI≥28). The cutoff points for overweight and obesity were 24 and 28, respectively.

Sleep quality
We used the Chinese version of the Pittsburgh Sleep Quality Index (PSQI), which has good reliability, to assess the sleep quality of college students over the previous month. The PSQI consists of 19 items that generate seven components: subjective sleep quality; sleep latency; sleep duration; habitual sleep efficiency; sleep disturbances; use of sleep medication; and daytime dysfunction. Each item is rated on a four-point scale ranging from “none” (zero) to “three times a week” (three). The sum of the scores for all items is the total PSQI score, with a total score range of 0 to 21 points. Higher global scores indicate worse sleep quality. The evaluation of sleep quality followed global recommended standards (score ≤5: good; score >5: poor). In addition, we divided the PSQI into two more detailed classifications for further research.

Statistical analyses
All data were double entered into an EpiData3.1 database; SPSS16.0 software was used to analyze data on BMI and sleep quality among the university students. The chi-square test or Fisher’s exact test was used for categorical variables, and one-way ANOVA was used for continuous variables. A two-tailed P-value of <0.05 was considered significant for all tests.

RESULTS
Body type of university students

There were 1328 participants, 470 males (35.4%) and 858 females (64.6%); their age ranged from 19 to 23 years (mean±SD = 19.50±1.33). The overall
mean BMI was 20.63 (SD=2.83); male: mean±SD = 21.67±3.29, female: mean±SD = 20.06±2.37. Among the university students, 249 (18.75%) were underweight, 958 (72.14%) were of normal weight, 91 (6.85%) were overweight, and 30 (2.26%) were obese. The two genders and different years had different prevalence of underweight, overweight and obesity, and the differences were statistically significant (p<0.05; Table 1).

Sleep quality of university students
The mean score on the PSQI was 4.91 (SD=2.67), and no statistically significant differences were found for overall quality of sleep between male and female students, or among different years (p=0.077). Among the seven dimensions of the PSQI score, a gender difference and a year difference existed for sleep duration and use of sleep medication (p<0.05). In addition, the sleep disturbance score differed between male and female students, and there was a significant difference in the sleep latency score (p<0.05) (Table 2).

The associations between sleep quality and BMI
On testing the correlation between the two kinds of classification of PSQI and overweight or obesity, we found that the PSQI 2 and BMI among females showed some correlation (Table 3).

**TABLE 1 – BMI OF COLLEGE STUDENTS (PERCENTAGE)**

| Variable | Underweight | Normal | Overweight | Obesity | Total | χ² | p |
|----------|-------------|--------|------------|---------|-------|----|---|
| gender   |             |        |            |         |       |    |   |
| Male     | 52(11.1)    | 335(71.3) | 62(13.2)   | 21(4.5) | 470   | 81.37 | 0.00 |

**DISCUSSION**

The mean BMI of the students included in the study was 20.63, which was lower than that of Chinese adults. We also found that the prevalence of overweight and obesity in male students was higher than that in females. Moreover, the prevalence of underweight was obviously higher than the prevalence of obesity. Wronka et al. conducted a study on 1129 women in the south of Poland; they observed that the prevalence of underweight was higher than the prevalence of overweight and obesity, especially in students from high income families. Previous studies have also observed that gender is a contributing factor for the classification of BMI. The two main explanations for this phenomenon are that university students have unhealthy eating behavior and inadequate nutrient intake, and that females may have higher leptin concentrations than males. In addition, we found that the prevalence of obesity among senior students was higher than in other years, and that the prevalence of obesity in first-year students was lower than in other years.

The proportion with poor quality of sleep was 36.5% for men and 39.1% for women; this result is lower than that found by Mesquita’s research on sleep quality in Brazilian college students.
ever, the sleep quality of university students is generally poor, and comprehensive measures should be taken to improve the quality of sleep and promote college students’ physical and mental health. Our study found that sleep quality was not associated with sex or year, which is consistent with previous studies. Sleep quality was measured on seven dimensions. Sleep duration, sleep disturbance and medication use were associated with sex. Through the study of classification variables, sleep quality was found to be good in more male than female students.

After subdividing the low PSQI scores, we found that sleep quality in female students, but not in males, was associated with BMI; however, Mota and Vale reported that poor sleep quality was not associated with BMI. The seven dimensions of the sleep quality score were not associated with different BMI categories in males in our study, but the score relating to the use of sleep medication was associated with different BMI categories in females: obese females were significantly more likely to use such drugs than non-obese females. Female students may be more sensitive to problems with sleep quality and BMI. Furthermore, the use of different classifications on the PSQI can give different relationships between BMI and sleep quality, which suggests that different classifications of PSQI may influence the study of sleep quality and should be chosen carefully in future studies.

Strengths and Limitations

The strengths of our study include a large sample size, the use of well-trained interviewers and the valuable data pool. However, limitations to our study must also be considered when interpreting results. First, the sample size in different groups was small; for example, there was a small sample of senior students and more females were included than males, which may have affected the correlation found between sleep quality and BMI. Second, none of these findings demonstrated a causal relationship, due to the cross-sectional design of the study, and we did not investigate the correlation with the university programs and their relevance. Finally, we did not analyze the college students’ eating habits or practice of physical exercise, which previous studies have found to be related to sleep and obesity.

CONCLUSION

Our study shows that BMI and sleep quality of college students vary according to gender and year. After adjusting the classification of PSQI, we found that sleep quality differed between male and female students. By researching the different dimensions of the PSQI, we also found that the relationship between the BMI and sleep quality was important only in female students who took hypnotic drugs. College students are a special group, and therefore it is important to study their sleep quality, as well as the relationship between sleep quality and body type. In addition, the government and school-related departments concerned should place great importance on the mental and physical health of college students.

RESUMO

OBJETIVO: O objetivo do estudo era investigar a prevalência de obesidade e sobrepego e sua relação com a qualidade do sono em estudantes universitários da província de Anhui, China.

METODOLOGIA: Um estudo transversal foi realizado na China com 1328 participantes. A prevalência de baixo peso e obesidade em estudantes universitários foi estimada com base nas referências do Grupo de Trabalho sobre Obesidade da China. A qualidade do sono foi avaliada utilizando o padrão PSQI (Pittsburgh Sleep Quality Index).

RESULTADOS: O estudo incluiu 470 homens e 858 mulheres, todos estudantes universitários de Anhui; 4,4% das mulheres e 17,7% dos homens foram classificados com sobrepego ou obesidade. A prevalência do obesidade em homens foi significativamente maior do que em mulheres, e a prevalência da obesidade nos últimos anos foi maior do que em outras categorias (P < 0,05). Em geral, a pontuação média de qualidade do sono foi 4,91 ± 2,67; 36,5% dos homens e 39,1% das mulheres tiveram uma qualidade de sono ruim (PSQI > 5). Considerando os sete componentes da qualidade do sono, a duração do sono e o uso de medicação para dormir apresentaram diferenças significativas entre estudantes homens e mulheres de anos diferentes (P < 0,05). Uma clara correlação foi encontrada entre a qualidade do sono e o Índice de Massa corporal (IMC) (P < 0,0000) em mulheres que usavam drogas hipnóticas.

CONCLUSÃO: Este estudo sugere que a qualidade do sono dos homens está provavelmente associada com o IMC. Os universitários são um grupo especial de jovens adultos, por isso é importante para estudar a causa da sua má qualidade do sono e sua relação com o IMC, para que seja possível melhorar a saúde dos estudantes universitários.

PALAVRAS-CHAVE: IMC, a qualidade do sono; estudantes universitários

Agradecimentos

O estudo incluiu 470 homens e 858 mulheres, todos estudantes universitários de Anhui; 4,4% das mulheres e 17,7% dos homens foram classificados com sobrepego ou obesidade. A prevalência do obesidade em homens foi significativamente maior do que em mulheres, e a prevalência da obesidade nos últimos anos foi maior do que em outras categorias (P < 0,05). Em geral, a pontuação média de qualidade do sono foi 4,91 ± 2,67; 36,5% dos homens e 39,1% das mulheres tiveram uma qualidade de sono ruim (PSQI > 5). Considerando os sete componentes da qualidade do sono, a duração do sono e o uso de medicação para dormir apresentaram diferenças significativas entre estudantes homens e mulheres de anos diferentes (P < 0,05). Uma clara correlação foi encontrada entre a qualidade do sono e o Índice de Massa corporal (IMC) (P < 0,0000) em mulheres que usavam drogas hipnóticas.

CONCLUSÃO: Este estudo sugere que a qualidade do sono dos homens está provavelmente associada com o IMC. Os universitários são um grupo especial de jovens adultos, por isso é importante para estudar a causa da sua má qualidade do sono e sua relação com o IMC, para que seja possível melhorar a saúde dos estudantes universitários.
