mTOR inhibitors and risk of ovarian cysts: a systematic review and meta-analysis

Fabio Parazzini,1 Sandro Gerli,2 Alessandro Favilli,2 Michele Vignali,3 Elena Ricci 1, Sonia Cipriani,4 Francesca Chiaffarino 3, Andrea Dell’acqua,1 Sergio Harari,1 Stefano Bianchi1

ABSTRACT

Objective To summarise the available evidence on frequency of ovarian cyst development during mammalian target of rapamycin inhibitors (mTORi) treatment.

Methods PubMed/Medline and EMBASE databases were searched, from 1990 up to March 2020, using the following keywords: ‘tacrolimus’, ‘sirolimus’, ‘temsirolimus’, ‘everolimus’, ‘deforolimus’, ‘mTOR’ and ‘ovarian cysts’ (Limit: Human, English, full article). Studies were selected for the review if they met the following criteria: clinical studies, studies reporting original data, studies reporting the number of patients using mTORi, studies reporting the number of patients with ovarian cysts.

We selected 7 of 20 retrieved studies. Study design, population, sample size, criteria for diagnosis of ovarian cysts, drug doses and follow-up length were extracted. Pooled estimate of incidence was calculated for ovarian cysts as a percentage, with 95% CI.

Results Four hundred-six women were included in the selected studies. The pooled incidence was 37.0% (95% CI 29.1% to 44.9%) for clinically significant ovarian cysts, drug doses and follow-up length were extracted. Pooled estimate of incidence was calculated for ovarian cysts as a percentage, with 95% CI.

Conclusion Ovarian cyst development is a common adverse event during mammalian suppression treatment with mTORi. These cysts are benign conditions, but they require pelvic ultrasound follow-up and in some cases hospital admission and surgery.

INTRODUCTION

The mammalian target of rapamycin (mTOR) kinase regulates cell growth and metabolism in response to intracellular and extracellular energetic stimuli and growth factors. The importance of mTOR in health and diseases has pushed the development of drugs that inhibit mTOR signalling (mTOR inhibitors, mTORi), including rapalogs, such as sirolimus (SRL), temsirolimus, tacrolimus (TAC), everolimus and deforolimus, which complex with FK506-binding protein 12 to inhibit mTOR complex 1 activity in an allosteric manner, or the more recent ATP-competitive mTORi (such as dactolobis), which targets the catalytic site of the enzyme.

mTORi are used as targeted therapy for tumours (in particular renal carcinoma). Further mTORi inhibit T-cell proliferation and proliferative responses induced by several cytokines, including interleukin 1, interleukin 2, interleukin 3, interleukin 4, interleukin 6, insulin-like growth factor, platelet-derived growth factor and colony-stimulating factors and they have been used in combination therapy with corticosteroids and cyclosporine (CsA) in patients who received kidney transplantation to prevent organ rejection, and in the treatment of rheumatoid arthritis.

Due to the widespread role of mTOR, mTORi may impact different organs and systems causing side effects that could be serious and/or debilitating. The mTOR signalling pathway is known to regulate ovarian function; thus it is conceivable that mTORi may affect ovarian activity.

In the early 2000s, observational data have suggested that mTORi, sirolimus in particular, may cause menstrual irregularities and high-volume ovarian cysts, needing surgical procedure.

This study summarises the available evidence on frequency of ovarian cyst development during mTORi treatment.

Most studies included an extremely limited number of subjects and although meta-analyses provide an explicit method for synthesising evidence and overcome the low power of the single studies, they may not be as valuable as a single large observational study.

Strengths and limitations of this study

► Due to the widespread role of mammalian target of rapamycin (mTOR), mTOR inhibitors (mTORi) may impact different organs and systems causing side effects that could be serious and/or debilitating.

► The mTOR signalling pathway is known to regulate ovarian function; thus it is conceivable that mTORi may affect ovarian activity.

► In the early 2000s, observational data have suggested that mTORi, sirolimus in particular, may cause menstrual irregularities and high-volume ovarian cysts, needing surgical procedure.

► This study summarises the available evidence on frequency of ovarian cyst development during mTORi treatment.

► Most studies included an extremely limited number of subjects and although meta-analyses provide an explicit method for synthesising evidence and overcome the low power of the single studies, they may not be as valuable as a single large observational study.

ovarian function; thus, it is conceivable that mTORi may affect ovarian activity. Along this line, in the early 2000s, observational data have suggested that mTORi, SRL, in particular, may cause menstrual irregularities and high-volume ovarian cysts, needing surgical procedure.

In this paper, we reviewed the available data on the reported frequency of ovarian cysts, during treatment with mTORi SRL.

METHODS

We searched the PubMed (National Library of Medicine, Washington, District of Columbia, USA) and EMBASE databases from 1990 up to March 2020 using different combinations of the following keywords: (a) ‘tacrolimus’, ‘sirolimus’, ‘temsirolimus’, ‘everolimus’, ‘deforolimus’ and ‘mTOR’ and ‘ovarian cysts’ (Limit: Human, English, full article) (see online supplemental file 1).

Furthermore, we reviewed reference lists of retrieved articles to search for other pertinent studies.

Two authors reviewed the papers and independently selected the articles eligible for the systematic review and extracted data. Any disagreements were submitted to a third reviewer to solve.

Inclusion criteria

Studies were selected for the review if they met all the following criteria: clinical studies, studies reporting original data, studies reporting number of patients using mTORi, studies reporting number of patients with ovarian cysts.

Exclusion criteria

Reviews, commentaries and case reports were excluded from the review.

The present review and meta-analysis were conducted according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guideline.

Patients and public involvement

It was not appropriate to involve patients or the public in our research.

Data extraction

A Patient, Intervention, Comparator, Outcome, Study design structure was used to develop the study questions and the inclusion/exclusion criteria. The question was, ‘Is there a relationship between mTORi sirolimus and ovarian cysts?’ (table 1).

For each study, the following information was extracted: first author’s last name; year of publication; country of origin; design of the study; number of subjects treated with SRL; age if present; criteria for the diagnosis of ovarian cysts; type and dose of drug; length of follow-up; number of women with newly diagnosed ovarian cyst. Further, we have collected information on the clinically significant ovarian cysts. This group includes symptomatic cysts, cyst >6 cm and cysts requiring surgery (see below).

Quality assessment

The quality of the studies included in the review was assessed using the Newcastle-Ottawa Scale (NOS).

This instrument was developed to assess the quality of non-randomised studies, specifically cohort and case-control studies. Studies were judged based on three broad categories: selection of study groups, comparability of study groups and assessment of outcome (cohort studies) or ascertainment of exposure (case-control studies). The maximum score was 9.

Randomised controlled trials (RCTs) were evaluated using the revised Cochrane risk-of-bias tool for randomised trials.

Data synthesis

The primary outcomes assessed were ovarian cyst (overall and clinically significant) in the total series and, if available, separately for premenopausal and postmenopausal women.

For each study with binary outcomes, we calculated the 95% CI of the estimated proportion. To evaluate the association between ovarian malignancy and menopausal status, we computed Pearson $\chi^2$ test for heterogeneity and relative p value.

We used Metaprop, a command implemented in Stata to compute meta-analysis of proportions (StataCorp. 2015. Stata Statistical Software: Release 14. College Station, Texas, USA: StataCorp LP). Freeman-Tukey method was applied to include, in the computation, the studies with outcome proportion equal zero.

Estimates of proportion and 95% CI were calculated by using random effect model. To evaluate heterogeneous among studies, heterogeneity $\chi^2$ p value was also reported. We assessed the heterogeneity among studies using the $\chi^2$ test and quantified it using the I2 statistic. Results were defined as heterogeneous for p values less than 0.10. We computed summary estimates for ovarian cysts. We also rerun the analysis excluding the most extreme result, to evaluate if the summary estimate substantially changed.

Table 1  Patient, Intervention, Comparator, Outcome, Study criteria for inclusion and exclusion of studies

| Parameter   | Inclusion criteria                                                                 | Data extraction                  |
|-------------|------------------------------------------------------------------------------------|----------------------------------|
| Patient     | Women treated with mTOR inhibitors                                                 | Location, age, type of patients  |
| Intervention| mTOR inhibitors                                                                     | Dose and duration                 |
| Comparator  | No treatment                                                                       | Group definition                  |

mTOR, mammalian target of rapamycin.
RESULTS
The initial search retrieved 16 abstracts from Pubmed, and 13 from EMBASE. Nine publications were retrieved both in Pubmed/Medline and EMBASE, and 11 were excluded after reviewing abstracts: five laboratory studies, three case reports, one not including drugs of interest, and two reviews.

Thus, nine publications remained to be fully read. One paper was excluded because it was duplicate and another because the number of cases of ovarian cysts was not reported, although they were described as ‘very frequent’. One paper reported the update of a previous one; thus, the latter was excluded from the main analysis but included in the subanalysis for menopausal status, since this information was missing in the updated report. Figure 1 shows the flow diagram of the literature search results.

A total of seven studies have been identified: they were conducted in samples of women with type 1 diabetes mellitus (T1DM) who underwent allogenic islet transplantation (AIT), in women with polycystic kidney disease and in renal transplant recipients. Main methodological characteristics are presented in Table 2.

Three studies were retrospective chart review, and two were RCTs. Three studies included women with T1DM who underwent allogenic islet transplantation, three kidney transplantation recipients, and one study enrolled women with autosomal dominant polycystic kidney disease.

Diagnosis of ovarian cysts was based on pelvic ultrasound examination in four studies with MRI without contrast in one study, whereas two did not report the diagnostic criteria.

SRL was given at increasing dose to reach serum levels ranging from 7 to 15 ng/mL when used in association with SRL, or 1 ng/mL when used in association with mycophenolate mofetil (1 g two times per day as tolerated). Overall, the considered studies included 406 women who received SRL alone or in combination with other drugs, with mean follow-up ranging from 12 to 95 months.

Quality of selected studies
Both Braun et al (10c) and Gaber et al (11) had low risk of bias according to the Cochrane risk of bias tool (table 3). As regards observational cohorts, using the Newcastle-Ottawa Scale tool, study quality was deemed good (9 out of 9) in Bachmann et al’s paper. Alfdhli et al’s study was of some concern because it was unclear if baseline ultrasound scans were detailed enough to identify ovarian cysts. Del Olmo Garcia et al presented mainly descriptive articles, including 18 (13 of whom already included in the paper by Cure et al (11) and 6 women, respectively. Therefore, the possibility of some NOS quality item evaluation was debatable (ie, if sample size was too little to control for important factors or if a not exposed cohort did exist).

Main results
Table 4 reports the frequency of ovarian cysts in women treated with SRL, SRL+TAC and SRL or everolimus. Two studies reported the frequency in strata of menopausal status, suggesting that premenopausal women were at higher risk of developing ovarian cysts during mTORi treatment.

Systematic review
Gaber et al conducted a RCT to evaluate the efficacy and safety of SRL plus TAC versus SRL plus CsA in high-risk renal allograft recipients. A total of 202 women were randomly assigned before transplant to receive SRL–TAC (104 women) or SRL–CsA (98 women) with corticosteroids. Patients randomly assigned to SRL–TAC received a 10 mg loading dose of SRL on days 1 and 2, and 5 mg one time a day, thereafter, adjusted to achieve whole blood trough concentrations from 10 to 15 ng/mL (measured by high performance liquid chromatography methodology). Up to 0.2 mg/kg/day of TAC was administered in divided oral doses (two times per day) to achieve whole blood concentrations from 10 to 15 ng/mL between day 1 and week 2, from 5 to 10 ng/mL between weeks 2 and 26, and from 3 to 5 ng/mL between weeks 26 and 52 (measured by TDx monoclonal antibody assay or equivalent methodology). Patients randomly assigned to SRL–CsA received a larger 15 mg loading dose of SRL on day 1, and 5 mg one time a day, thereafter, adjusted to achieve the same whole blood trough concentrations as the patients assigned to SRL–TAC. One case of ovarian cyst was observed in the SRL–TAC group (1.0%) and seven in the SRL–CsA group (7.1%) (p=0.031). In this study, no information on severity of cysts (ie, for example dimension or presence of pain) was reported.

Alfdhli et al conducted a chart review retrospective study in 57 women who underwent islet transplantation and received maintenance immunosuppression with SRL (tough levels 12–15 ng/mL for the first 3 months then...

A study can be awarded a maximum of one star for each numbered item within the Selection and Outcome categories. A maximum of two stars can be given for Comparability.

*We used the Newcastle-Ottawa quality assessment scale with maximum score 9, as presented at http://www.ohri.ca/programs/clinical_epidemiology/oxford.asp (accessed 24 April 2017). Most items were evaluated as '-' because of the small sample size or absence of not exposed cohort.

†For the assessment of randomised controlled studies, we used the revised Cochrane risk of bias tool as presented at https://sites.google.com/site/riskofbiastool/welcome/rob-2-0-tool/current-version-of-rob-2. RCT, randomised controlled trial.
a median of 235 (119–405) days after the first islet transplantation: 31 out of 44 (70.5%) premenopausal and 2 out of 13 (15.4%) postmenopausal women (p=0.001). Ovarian cysts occurred more frequently in subjects taking SRL plus TAC than those taking high doses of TAC plus mycophenolate mofetil (33/53, 62.3%, vs 0/4, 0%, p=0.027). No women using combined oral contraception developed ovarian cysts. Among women taking SRL, average SRL trough levels were similar between those who developed ovarian cysts and those who did not (median 12.1, IQR 10.9–13.3, vs 12.2, IQR 11.5–12.6 ng/mL, p=0.993).

SRL withdrawal was associated with a reduction in cyst size and resolution of cysts in 80% of subjects. The median maximal cyst diameter was 6.0 (3.8–7.6) cm. Most cysts were asymptomatic and noted incidentally on routine imaging. However, 14 subjects (42.4%) reported pelvic pain. In four cases, severe pelvic pain resulted in emergency room visits because of ovarian cyst rupture (n=2) or torsion (n=2). Histology was benign in all cases.

Del Olmo Garcia et al\(^\text{13}\) reported a total of 18 subjects (mean age at transplantation 48.5, SD 8.0 years) with T1DM, who underwent allogeneic transplantation and were treated with SRL, given orally pretransplant, at 0.2 mg/kg, and then adjusted to achieve trough levels of 12–15 ng/mL for the first 90 days and 7–12 ng/mL thereafter. After the transplant, they were followed for a mean time of 7.9 (SD 1.13) years. In this study, a total of ten ovarian cysts (56%) were observed. All the cysts were benign, but eight were considered complex because of haemorrhage, hydrosalpinx, cyst’s size (>6 cm), spontaneous rupture or need of surgery for resolution. Four women (40%) underwent cystectomy because of poor response to medical treatment. Part of this sample (13 out of 18) was previously described by Cure et al\(^\text{12}\), who reported that in four women, postmenopausal at the time they were transplanted, one case of ovarian cyst was observed, whereas out of nine premenopausal women seven developed ovarian cysts.

Braun et al\(^\text{10}\) reviewed the occurrence of ovarian cysts in a post hoc analysis of an open label randomised controlled phase II trial, conducted between March 2006 and March 2010. Women with autosomal dominant polycystic kidney disease were treated with 1.3–1.5 mg SRL per day for a

*Sirolimus (SRL)+cyclosporine.
TAC, tacrolimus.
Ovarian cysts were observed in 12 out of 21 patients in the SRL group, compared with 5 out of 18 patients in the control group (HR 4.4, 95% CI 1.1 to 26). Differences in ovarian cysts between SRL and control did not seem to depend on the contraceptive method (barrier methods: 7 out of 11 and 3 out of 9 patients in the SRL and control groups; oral contraceptives: 5 out of 10 and 2 out of 9 patients in the SRL and control groups). Clinical significance of ovarian cysts was not reported. One patient presented with acute abdominal pain and a large cyst of the left ovary while receiving SRL and underwent surgery.

Ignjatović et al reviewed 24 transplant patients (6 women) who switched from calcineurin inhibitors (CNI) to SRL from 2003 to 2011. Patients converted from CNI to SRL, with target serum levels 7–10 ng/mL for months 6–12 after transplant, and 5–10 ng/mL thereafter. Early after the conversion, two patients developed ovarian cysts with oligomenorrhea and reconverted to CNI, with cyst resolution and return to regular period.

Bachmann et al compared the effect of mTORi versus non-mTORi immunosuppression on the incidence, size and complication rate of ovarian cysts in renal transplant recipients. They retrospectively analysed 571 consecutive female kidney transplant patients between 2000 and 2008; they were followed-up till December 2012. Of those, 102 (17.8%) patients received mTORi for at least 1 month after transplantation. A total of 44 women (7.7%) with new ovarian cysts were reported, 21 among patients receiving mTORi (20.5%) and 23 in the control group (4.9%). This difference was statistically significant (p<0.001). The hospitalisation rate was also more frequent in the mTOR group, with 21 hospitalisations in 10 mTORi patients versus 9 hospitalisations in 8 control subjects (p=0.05). Ten women in the mTORi group (9.8%) versus eight in the control group (1.7%) had symptomatic, clinically significant ovarian cysts requiring surgery.

In our synthesis, we found an extremely high heterogeneity, that may be due to both the different criteria for diagnosis of ovarian cysts and the type of disease requiring mTORI use. For example, T1DM is associated with menstrual irregularity and PCOS, hence a higher basal frequency of ovarian cyst development. Another factor likely affecting heterogeneity was the active screening for ovarian cysts development in women on mTORi treatment. In particular, it appears that in the study with the lowest incidence, women did not routinely undergo abdominal scans: pelvic (ie, transvaginal) sonography would be the preferred imaging modality to exclude ovarian cysts.

In biological terms, mTORI may affect the levels of LH (Luteinizing Hormone) and FSH (Follicle Stimulating Hormone). Further, expression of progesterone receptors can be inhibited by SRL via the mTOR and inhibition of progesterone receptors in the ovaries may interfere with ovarian cysts development. However, the specific mechanisms linking mTORI exposure and risk of developing ovarian cysts are unknown.

This review and meta-analysis may be affected by potential limitations or bias.

Findings from this systematic review and meta-analysis are based on an extremely limited number of studies; thus the results should be considered cautiously. Taking this aspect into account, the general results confirm clinical suggestions that mTORI increase the frequency of benign ovarian cysts.

Among studies, the heterogeneity was remarkable. This finding may be due to the characteristics of the selected samples. First, two studies included women with T1DM who underwent AIT, three included women who underwent renal transplantation and one study women with autosomal dominant polycystic kidney. Then, the ascertainment of ovarian cysts was performed with different methodologies, variable imaging modalities and definitions (size, persistence) of ovarian cyst.

In our meta-analysis, the resulting estimate was 17.3% (95% CI 5.6% to 29.1%), heterogeneity $\chi^2$ 15.5, $p<0.001$ (figure 3).

**DISCUSSION**

This systematic review shows that, in women treated with mTORI, the incidences of ovarian cysts ranged between less than 10% to more than 50%, in different studies. The pooled incidence was 37%, 17% only considering clinically significant ovarian cysts. The risk seems to be higher among premenopausal women: two studies distinguished ovarian cyst incidence occurring in premenopausal and postmenopausal patients, with consistent results, suggesting that mTORI effect is higher in presence of spontaneous ovarian activity.

Where immunosuppression was achieved using mTORI as compared with non-mTORI, women on mTORI were at higher risk of developing ovarian cysts.

The limited data and the differences in the presentation of results do not provide the opportunity of analysing in detail the role of stopping mTORI on the clinical course of ovarian cysts or the protective role of oral contraceptive use.

In the study by Alfadhli *et al.*, SRL withdrawal was associated with a reduction in cyst size and resolution of cysts in 80% of subjects; however, the proportion with partial or complete cyst resolution was similar in those who did or did not discontinue SRL (12/15, 80%, vs 6/8, 75%, $p=NS$).

Another potential risk factor for the development of ovarian cysts during mTORI use was a previous history of ovarian cysts; Del Olmo Garcia *et al.* reported five patients with such a history.

Two studies compared mTORI versus non-mTORI immnosuppression. The pooled OR for ovarian cyst incidence was 4.62 (95% CI 2.58 to 8.28) and the pooled OR for clinically significant ovarian cysts was 5.56 (95% CI 2.34 to 14.67).

Finally, we pooled the incidence of clinically significant ovarian cysts in studies reporting this information. The resulting estimate was 17.3% (95% CI 5.6% to 29.1%), heterogeneity $\chi^2$ 15.5, $p<0.001$ (figure 3).
direction and the strength of this bias are not however clear.

Another limitation is the fact that most of studies included an extremely limited number of subjects. Although systematic reviews with meta-analyses provide an explicit method for synthesising evidence and overcome the low power of the single studies, they may not be as valuable as a single large observational study. Lastly, this study was not registered a priori.

Despite these limitations, consistent results among all studies give strong support to the general findings. Although the biological and clinical explanation of the results of our analysis is not totally clear, observational studies and clinical trials consistently suggest that ovarian cysts are a common adverse effect of mTORi. These cysts are benign conditions, but they require pelvic ultrasound follow-up and in some cases hospital admission and surgery. Based on these considerations, women and physicians should be warned in routine clinical practice about the gynaecological impact of long-term use of mTORi. Further the risk of ovarian cyst, together with the impact of mTORi on glucose metabolism, risk of diabetes and other potential adverse effects should be included in the risk benefit balance of mTORi use as immunosuppressive agents.
