APC2 is critical for ovarian WNT signalling control, fertility and tumour suppression

Noha-Ehssan Mohamed1,2,3, Trevor Hay1, Karen R. Reed1, Matthew J. Smalley1,† and Alan R. Clarke1,†

Abstract

Background: Canonical WNT signalling plays a critical role in the regulation of ovarian development; mis-regulation of this key pathway in the adult ovary is associated with subfertility and tumourigenesis. The roles of Adenomatous polyposis coli 2 (APC2), a little-studied WNT signalling pathway regulator, in ovarian homeostasis, fertility and tumourigenesis have not previously been explored. Here, we demonstrate essential roles of APC2 in regulating ovarian WNT signalling and ovarian homeostasis.

Methods: A detailed analysis of ovarian histology, gene expression, ovulation and hormone levels was carried out in 10 week old and in aged constitutive APC2-knockout (Apc2−/−) mice (mixed background). Statistical significance for qRT-PCR data was determined from 95% confidence intervals. Significance testing was performed using 2-tailed Student’s t-test, when 2 experimental cohorts were compared. When more were compared, ANOVA test was used, followed by a post-hoc test (LSD or Games-Howell). P-values of < 0.05 were considered statistically significant.

Results: APC2-deficiency resulted in activation of ovarian WNT signalling and sub-fertility driven by intra-ovarian defects. Follicular growth was perturbed, resulting in a reduced rate of ovulation and corpora lutea formation, which could not be rescued by administration of gonadotrophins. Defects in steroidogenesis and follicular vascularity contributed to the subfertility phenotype. Tumour incidence was assessed in aged APC2-deficient mice, which also carried a hypomorphic Apc allele. APC2-deficiency in these mice resulted in predisposition to granulosa cell tumour (GCT) formation, accompanied by acute tumour-associated WNT-signalling activation and a histologic pattern and molecular signature seen in human adult GCTs.

Conclusions: Our work adds APC2 to the growing list of WNT-signalling members that regulate ovarian homeostasis, fertility and suppress GCT formation. Importantly, given that the APC2-deficient mouse develops tumours that recapitulate the molecular signature and histological features of human adult GCTs, this mouse has excellent potential as a pre-clinical model to study ovarian subfertility and transitioning to GCT, tumour biology and for therapeutic testing.

Keywords: APC2, APC hypomorph, WNT signalling, Ovarian fertility, Ovarian cancer, Granulosa cell tumour

Background

The canonical WNT signalling pathway is central to numerous biological processes and diseases [1]. Within the ovary, the pathway has been shown to be essential for female sex differentiation during embryogenesis [2–9], however, in the adult ovary its role is less well defined. Conditional deletion of β-catenin within murine granulosa cells of antral follicles did not affect folliculogenesis or ovulation [10, 11], but its removal within oviducts and uteri led to abnormalities therein, with lack of implantation sites rendering mice infertile as a result [11]. Conditional deletion of Wnt4 in ovarian granulosa cells or germline deletion of Fzd4 in mice caused sub-fertility or complete infertility respectively [12, 13], but WNT signalling activity was not measured and it is unclear whether the reported phenotypes were caused by impaired ovarian canonical WNT signalling or by other mechanisms, potentially including non-canonical pathways. In mice with germline deletion of the WNT signalling agonist Fzd1,
17.6% of female mice were infertile and characterized by early follicle depletion, but with no concomitant change in total activated β-catenin levels [14]. Over-activation of canonical WNT signalling also has deleterious effects on ovarian homeostasis. Ovarian amplification of Rspos1 [15], deletion of Wnt5a (antagonist of canonical WNT signalling) [16] or expression of dominant stable β-catenin [10, 17] all resulted in up-regulated ovarian WNT signalling and ovarian subfertility caused by disruption of follicle growth [16, 17], ovulation and luteinisation [10, 15]. Taken together, these findings indicate the importance of tight regulation of canonical WNT signalling in growing follicles.

Human ovarian tumours are classified into epithelial ovarian cancers (90%), sex cord-stromal tumours (7%) and germ cell tumours (3%). Granulosa cell tumours (GCTs), which originate from granulosa cells of ovarian follicles, account for more than half of sex cord-stromal tumours [18]. WNT signalling mis-regulation has been implicated in adult GCT formation, as several studies have demonstrated increased β-catenin protein levels therein, with nuclear localisation in some cases [17, 19, 20]. A recent molecular study of GCTs showed epigenetic silencing of DKK3, the gene coding for the WNT-signalling antagonist Dickkopf, implying a need for WNT signalling activation in GCT development (25, 26). Furthermore, GEMMs in which WNT signalling was activated via the introduction of a gain-of-function mutation of R-spondin1 [15], or a degradation-resistant β-catenin [17], resulted in 15.8% or 57% of mice developing adult GCTs respectively.

Here, for the first time, we address the importance of APC2 in ovarian folliculogenesis, fertility and GCT formation. The ability of APC2 to regulate the β-catenin/WNT signalling pathway has been demonstrated in Drosophila and in cancer cell lines [21–25]. Structurally, APC2 possesses AXIN1 and β-catenin binding sites, which enable it to destabilize β-catenin, targeting it for degradation and suppressing its transcriptional activity [22, 26], in addition to the APC-basic domain which enables it to regulate cytoskeleton and microtubule association [27–31] and spindle anchoring during mitosis [32]. Importantly, however, in an in vivo setting, APC2-dependent regulation of WNT signalling is tissue-specific, occurring in the liver and intestine but not in the mammary gland [33, 34]. Little is known about how APC2 functions in adult ovaries, but APC2 loss has been reported in epithelial ovarian cancer [28, 35]. Here, we show that Apcc2-knockout mice [36] have a subfertility phenotype associated with an activation of ovarian WNT signalling, and that, on a hypomorphic Apc background [37, 38], loss of APC2 increases the incidence of ovarian GCTs which recapitulate the histologic pattern and molecular signature of human adult GCTs. Not only does this study extend our understanding of the tissue-specific regulation of WNT signalling, but also the APC2-deficient mouse has excellent potential as a pre-clinical model to study ovarian tumour biology and for therapeutic testing.

Methods

Animal models, fertility and ovulation rate

All experiments were carried out under the authority of UK Home Office personal and project licences and according to ARRIVE guidelines and following local ethical review. Mouse models were maintained on a mixed C57Bl6/J and 129/Ola background in open cages with ad libitum access to food and water. Genotyping for the constitutive knockout allele of Apc2 (Apc2<sup>−/−</sup>) and the hypomorphic allele of Apc (Apc<sup>β</sup>) [34, 36–38] were performed as previously described [34, 36] (Additional file 1: Table S1). Typically, experiments compared wild type, heterozygous Apc2-deleted and homozygous-Apc2-deleted mice, with a minimum of three animals per groups, unless otherwise specified. The breeding defect of Apc2 knockout animals made it difficult, in some cases, to use large n numbers for analysis; where this is the case it has been clearly indicated in the text. Animals were euthanased for analysis of ovarian tissue by an approved humane method (cervical dislocation) at the times indicated (typically 10 weeks old for functional analysis and 12 or 18 months for tumour studies).

To assess female fertility, retrospective analysis of breeding performance was analysed from cages in which two 7–11 week-old female mice of the experimental genotypes (Apc<sup>β/−</sup>, Apc<sup>2/−</sup> and Apc<sup>2/−</sup>) were housed with a 7–9 week-old male of the same genotype for 3 months (n = 4 cages). Litter sizes were determined at the time of weaning.

To determine ovulation rates, 10 week-old female mice were super-ovulated by a single intraperitoneal injection of 5 IU pregnant mare’s serum gonadotrophin (MSD animal health, UK), followed by 5 IU human chorionic gonadotrophin (MSD animal health, UK), 47 h later [39]. Mice were either euthanased 16–17 (for Cumulus Oophorus Complex retrieval) [40] or 22–24 h later (for histological analysis) by an approved humane method (cervical dislocation).

Cumulus Oophorus complex (COC) retrieval and characterization

After release from the oviducts, COCs were counted and examined by bright-field microscopy to assess morphology. Oocytes were freed from surrounding cumulus cells by addition of 40 µl of 4 mg/ml collagenase/dispase (Roche, Switzerland), dissolved in DMEM/F12 medium (Mediatech, USA), for 10 min, and examined to determine their integrity [41] and to measure their diameter [42].
**Histological analysis of ovaries**

Follicle counting was performed on ovaries from 10-week-old Apc2+/− and Apc2−/− mice, either from randomly cycling females staged manually (using the vaginal cytology method) and collected at diestrus stage \((n = 4)\) or 22–24 h post HCG administration \((n = 5)\). Each ovary was serially-sectioned into 100 5 μM sections and each 10th section was stained with H&E. Growing follicles were counted every 10th section, when an oocyte nucleus was visible. Identification and classification of growing follicles and atretic follicles were performed as previously described [43, 44]. The total number of follicles throughout the 10 counted sections was used. Follicle sizes were measured using a minimum of 4 diameters/follicle.

**Hormonal analysis**

Serum hormonal levels were measured in 10-week-old Apc2+/− and Apc2−/− mice at diestrus stage using ELISA kits for FSH (Novateinbio, USA) and LH (Enzo Life-sciences, UK).

**Immunohistochemistry**

Tissue sectioning and immunohistochemistry were performed as previously described [34], using primary antibodies listed in Additional file 1: Table S2. Sections were examined with an Olympus BX43 light microscope and microphotographs taken using a 5 Megapixel HD Microscope Camera (Leica MC170 HD, Germany).

**Quantitative RT-PCR analysis**

RNA was extracted from whole ovaries or tumour pieces using RNeasy Plus mini extraction kit (Qiagen, Germany) and reverse transcription performed using QuantiTect Reverse transcription kit (Qiagen, Germany). All quantitative real time rtPCR assays were carried out three times using TaqMan® universal master mix II with UNG (Applied Biosystems, USA), Taqman® assays (Additional file 1: Table S3) and QuantStudio™ 7 Flex Real Time PCR system (ThermoFisher, USA), and relative expression levels determined using QuantStudio™ 7 Real Time PCR software.

**Statistical analysis**

Statistical significance for qRT-PCR data was determined from 95% confidence intervals [45]. All other statistical analyses were performed using IBM SPSS version 20 (SPSS Inc., Chicago, IL, USA). Significance testing was performed using 2-tailed Student’s t-test, when 2 experimental cohorts were compared. When more were compared, ANOVA test was used, followed by a post-hoc test (LSD or Games-Howell). \(P\)-values of \(< 0.05\) were considered statistically significant.

**Results**

**APC2 deficiency results in sub-fertility**

To evaluate the role of APC2 in the biology of the adult ovary, the impact of APC2 deficiency on normal ovarian homeostasis and fertility was first assessed. A retrospective analysis of mating efficiencies of wild type, heterozygous or homozygous breeding trios (Apc2+/+, Apc2+/− or Apc2−/− respectively) demonstrated that time between pairing mice and first litter production was significantly longer in Apc2−/− mice (Fig. 1a). The number of gestations over the 3-month period following pairing was significantly reduced in Apc2−/− mice, with heterozygous mice also showing a reduction which did not reach significance (Fig. 1b). Overall, there was a 40% reduction in the cumulative number of pups weaned over 3 months from Apc2+/− trios, compared to Apc2+/+, and this reduction was even more pronounced in Apc2−/− mice (Fig. 1c). Indeed, one Apc2−/− trio was completely infertile over this period.

Histology of ovaries, oviducts and uteri from 10-week-old virgin Apc2+/+ and Apc2−/− mice revealed no gross morphological differences in the oviducts and uteri (representative images in Additional file 2: Figure S1). No problems were reported during labour in any of the experimental groups; it is therefore unlikely that uterine problems contribute to the observed subfertility phenotype. However, there was a significant decrease in the number of corpora lutea formed in Apc2−/− ovaries (Fig. 1d, e & f), while the total number of growing follicles was increased, but not significantly (Fig. 1g). Morphometric and histochemical analysis of corpora lutea did not reveal any histological differences in these structures between Apc2+/+ and Apc2−/− ovaries (Additional file 3: Figure S2). Collectively, these findings suggest reduced ovulation is the cause of the subfertility observed in Apc2-deficient mice.

**Subfertility in APC2-deficient female mice is caused by intra-ovarian defects**

Given the constitutive nature of the Apc2 gene deletion in our mice, the genotype dose-dependent reduction in fertility, potentially as a result of an ovulation defect, may be due to defects in extra-ovarian regulation of ovarian function, triggered by hypothalamic/pituitary endocrine signals. To address this, follicle stimulating hormone (FSH) and luteinizing hormones (LH) levels in serum from 10-week old virgin Apc2+/+ and Apc2−/− female mice at diestrus stage were analysed by ELISA, but showed no differences (Additional file 4: Figure S3)a, b, suggesting hypothalamic/pituitary signals are not affected by Apc2 deletion.

Next, to determine whether the response of the ovary to endocrine signals was compromised in the context of Apc2 deletion, exogenous gonadotrophins were administered to
Fig. 1 APC2 loss causes subfertility in adult female mice. 

a) Mating efficiency of Apc2 experimental genotypes as a function of time recorded in days between pairing the mice and delivering the first litter. $N = 4$ breeding cages each with one Apc2$^{+/+}$, Apc2$^{+/−}$ or Apc2$^{−/−}$ male crossed with 2 Apc2$^{+/+}$, 2 Apc2$^{+/−}$ or 2 Apc2$^{−/−}$ female respectively. One Apc2$^{−/−}$ trio was completely sterile (*$P < 0.05$).

b) Breeding efficiency as reflected by number of gestations occurring in a 3 month period (mean ± S.E, $n = 4$).

c) Cumulative number of pups weaned in a 3 month period from 4 breeding pairs. Statistical significance between groups was determined using ANOVA test followed by Games-Howell post hoc analysis (variances of experimental groups were not homogeneous, tested by Levene's test).

f, g) Histograms showing total number of (f) corpora lutea, and (g) healthy growing follicles, counted across 100 serial sections of four ovaries collected from four animals at diestrus stage (mean ± SE; *$P < 0.05$, t-test)
induce superovulation in 10-week-old virgin $Apc2^{+/+}$, $Apc2^{-/-}$ and $Apc2^{−/−}$ mice. There was a gene dose-dependent decrease in the number of cumulus ophorous complexes (COCs) collected from the ampulla post-superovulation (Fig. 2a). However, morphological analysis of the COCs demonstrated that all oocytes were of comparable size, surrounded by a layer of cumulus cells of comparable thickness, and were healthy, with no signs of fragmentation, irrespective of genotype (Fig. 2b, c).

Importantly, histological analysis post-superovulation demonstrated a significant reduction in the number of corpora lutea in super-ovulated $Apc2^{-/-}$ ovaries compared to $Apc2^{+/+}$ (Fig. 2d,e,f). As with unstimulated ovaries, a slight, but non-significant, increase in the number of healthy growing follicles in $Apc2^{-/-}$ ovaries was observed (Fig. 2d,e,g). Taken together, these findings suggest that the subfertility phenotype seen in APC2-deficient female mice is not due to extra-ovarian defects in pituitary gonadotrophin secretion, but rather due to intra-ovarian defects in response to gonadotrophins that result in reduced ovulation. Therefore, expression levels of the ovarian gonadotrophin receptors $Fshr$ and $Lhcgr$, together with the steroid hormone receptors $Pgr$, $Esr1$, $Esr2$ and $Ar$, were assessed in ovaries from $Apc2^{+/+}$ and $Apc2^{−/−}$ mice. Significant over-expression of $Lhcgr$ was evident in $Apc2^{-/-}$ ovaries (Fig. 2h), but the other receptors were unaltered. Importantly, the LH receptor is a target of canonical WNT signalling [46], and its over-expression has previously been associated with infertility in mice [47].

Detailed morphometric analysis, on serial-sectioned ovaries collected at diestrus stage from $Apc2^{+/+}$ and $Apc2^{−/−}$ mice, demonstrated that the trend for an increase in the total number of healthy growing follicles in $Apc2^{-/-}$ ovaries (Fig. 1g), was restricted to the number of primary and antral follicles (Fig. 3a). Size distribution analysis for healthy antral and pre-ovulatory follicles demonstrated a significant increase in the percentage of small follicles (diameter < 200 μm) and a significant decrease in the percentage of larger follicles (diameter > 300 μm) in $Apc2^{-/-}$ ovaries (Fig. 3b). Analysis of atretic follicles was undertaken to determine whether increased atresia was causing the reduction in larger follicles in $Apc2^{-/-}$ ovaries, but their total number and size distribution were not significantly altered (Additional file 4: Figure S3c,d). IHC for Ki67 revealed that proliferation was unaltered in follicular granulosa or theca cells (Additional file 4: Figure S3). However, apoptosis, as measured by cleaved caspase 3 IHC, was significantly increased in granulosa cells in $Apc2^{-/-}$ follicles (Fig. 3c, d,e). Histological analysis of pre-ovulatory follicles together with gene expression analysis of EFG ligands and receptor did not reveal defects in ovulation (Additional file 4: Figure S3f,g). Thus, APC2 deficiency increases granulosa cell apoptosis, restricting follicular growth and reducing their ability to reach the pre-ovulatory stage.

**APC2 deficiency activates ovarian WNT signalling and upregulates Foxo1 expression**

As APC2 is a known regulator of canonical WNT signalling, we investigated whether dysregulated WNT signalling was mechanistically linked to the restriction in follicular growth in $Apc2^{-/-}$ ovaries. Ovarian subcellular localization of β-catenin was assessed by immunohistochemistry (IHC), and expression of a standard panel of WNT target genes was determined by qRT-PCR, using whole ovaries collected at diestrus stage from 10-week-old virgin control ($Apc2^{+/+}$) and APC2-knockout ($Apc2^{−/−}$) mice. IHC analysis of β-catenin revealed a comparable pattern of expression in all ovarian compartments between control and knockout ovaries (Additional file 5: Figure S4), although increased staining intensity was notable in atretic follicles from $Apc2^{-/-}$ ovaries (Fig. 4a). qRT-PCR analysis revealed a significant increase in the expression levels of $Apc$, $Axin2$, $Ctnmb1$, $Fgf1$ and $Lgr5$ in $Apc2^{-/-}$ ovaries compared to control ovaries (Fig. 4b). However, there were no significant changes in $Cd44$, $Lef1$ and $Wif1$.

Given the established role of the FOX family of transcription factors as regulators of apoptosis within ovarian granulosa cells [48–50], and their increased expression in granulosa cells of cultured follicles post-WNT signalling activation [51, 52], gene expression levels for $Foxo1$, $Foxo3$ and $Foxl2$ were analysed in $Apc2^{-/-}$ and $Apc2^{−/−}$ whole ovaries. A significant increase in $Foxo1$ expression levels was seen in $Apc2^{-/-}$ ovaries (Fig. 4c). Furthermore, the FOXO target genes $Bcl6$ and $Cdkn1b$ were significantly upregulated in $Apc2^{-/-}$ ovaries compared to controls (Fig. 4d).

The PTEN/P13K/AKT signalling pathway is an established regulator of FOXO transcriptional activity and post-translational modification [53]. On activation of AKT, FOXO proteins are inactivated by phosphorylation and translocated from nucleus to cytoplasm [53]. In addition, the crosstalk between activated WNT signalling and PTEN, causing the over-expression of the latter, is well established [16, 17, 54]. IHC analysis of PTEN, p-AKT and p-FOXO1,3,4 in $Apc2^{+/+}$ and $Apc2^{−/−}$ ovaries revealed that PTEN expression was stronger in theca and granulosa cells of $Apc2^{-/-}$ follicles (Fig. 4e). This was accompanied by a reduction in p-AKT immunostaining in $Apc2^{-/-}$ granulosa cells (Fig. 4f) and a consequent reduction in p-FOXO1,3,4 levels (Fig. 4g). Thus, the increased apoptosis seen in $Apc2^{-/-}$ follicles is likely due to upregulation of $Foxo1$ and its downstream effector genes, secondary to decreased activation of P13K/p-AKT signalling caused by PTEN upregulation.
APC2-deficient ovaries show impaired vascularisation and steroidogenesis

Interaction between β-catenin and FOXO1 has been previously described to affect tight junctions in endothelial cells disrupting angiogenesis [55]. Follicular growth impairment has been shown to occur following angiogenesis disruption, because the vascular network surrounding the growing follicles is essential for follicular development [56]. IHC for CD34 was used to compare follicular vascularization between Apc2+/+ and Apc2−/− ovaries. While late antral/pre-ovulatory follicles in Apc2+/+ ovaries were surrounded by 2 continuous layers of endothelial
Fig. 2 Exogenous gonadotrophin administration fails to reverse ovarian subfertility of APC2-deficient female mice. a APC2-deficiency caused a gene dose-dependent decrease in the number of ovulated COCs (mean ± SE) retrieved from the oviducts post-superovulation. b Upper panels, representative photomicrographs of retrieved COCs showing the presence of oocytes (black arrows) surrounded by cumulus cells (red arrows). Bar = 200 μm. Lower panels, oocytes freed from cumulus cells. Bar = 50 μm. c Average oocyte diameter (mean ± SE) among experimental groups, showing no difference. n = 4 for Apc2+/+, n = 3 for Apc2+/-, n = 5 for Apc2−/−. Statistical significance between groups in panels a – c was determined using ANOVA test followed by LSD post hoc analysis (variances of experiment groups were homogeneous tested by Levene’s test). d, e Representative photomicrographs of (d) Apc2+/+ and (e) Apc2−/− superovulated ovaries, showing growing follicles (red arrows) and corpora lutea (black arrows). Bar = 500 μm. f, g Total number of (f) corpora lutea, and (g) healthy follicles counted across 100 serial sections of five superovulated stage-matched ovaries from different animals (mean ± SE; *P < 0.05, t-test). h Gene expression levels of hormone receptors by qRT-PCR on RNA extracted from whole ovaries of Apc2+/+ and Apc2−/− 10-week-old female mice. Relative expression levels are normalized to Actb expression. N = 4 except for lhgr and Ar in Apc2−/− where n = 3 (mean ± 95% confidence intervals; **P < 0.01, determined from confidence intervals) [45].

Fig. 3 APC2-deficiency impairs follicular growth in the ovary. a Histogram showing total number of primary (1y), secondary (2y), antral and pre-ovulatory follicles in Apc2+/+ and Apc2−/− ovarian sections (mean ± SE; n = 4; no significant differences, t-test). b Size distribution of healthy antral and pre-ovulatory follicles (mean ± SE; n = 4; *P < 0.05, t-test). c Histogram showing a > 2-fold increase of apoptosis in granulosa cells of Apc2−/− follicles (mean ± SE; n = 4; *P < 0.05, t-test). d, e Representative photomicrographs of cleaved caspase 3 immunostaining in (d) Apc2−/− and (e) Apc2+/+ granulosa cells. Bars = 100 μm.
cells, those in Apc2−/− mice showed discontinuous layers (Fig. 5a). Furthermore, a significantly reduced level of Vegfa expression (Fig. 5b) supports the notion of impaired vascularisation within Apc2−/− ovaries, although it could, in part, be attributed to the reduced number of corpora lutea.

Negative regulation of follicle steroidogenesis by canonical WNT signalling has also previously been demonstrated [52]. We therefore examined the expression of key enzymes required for steroidogenesis in Apc2 knockout ovaries. We found there was significantly reduced expression of both Cyp17a1 (coding for steroid 17α-
hydroxylase/17,20 lyase) and Cyp19a1 (coding for aromatase) in Apc2−/− ovaries compared to Apc2+/+ ovaries (Fig. 5c).

Therefore, activation of WNT signalling in Apc2 knockout ovaries results in overexpression of PTEN and a reduction in activity of steroidogenesis and angiogenic pathways. These metabolic defects combine to result in a reduced number of follicles maturing to the ovulatory stage.

Long-term activation of WNT signalling by APC/APC2 deficiency, results in ovarian adult granulosa cell tumour formation

Because of the WNT signalling-dependent defects observed in 10-week-old Apc2 knockout mice, and the potential role of WNT signalling in driving ovarian tumour development in mice [15, 17, 54, 57, 58], we aged for up to 18 months cohorts of mice in which WNT signalling was activated to different levels using a hypomorphic Apc allele (weak activation of canonical WNT signalling), hypomorphic Apc plus Apc2+/− knockout (moderate activation) or hypomorphic Apc plus Apc2−/− knockout (strong activation). No gross ovarian tumours were detected in any cohorts at 6 months of age; however 6/29 (20.7%) of the APC2-deficient cohorts (Apc2+/− and Apc2−/− cohorts on the background of hypomorphic Apc) had developed adult ovarian GCTs at 12–18 months of age as compared to 1/19 (5.26%) of the APC2-proficient (hypomorphic Apc only) cohort developing ovarian GCT at 18 months of age (Table 1).

The tumours ranged from small microscopic in situ tumours to large macroscopic tumours (Fig. 6a-e). Morphologically, they recapitulated human ovarian adult GCTs and showed a range of different histological patterns (Fig. 6f-l). Cells were highly anaplastic (Fig. 6m) and mitotic figures were evident (Fig. 6n). Call-Exner bodies (formed of follicle remnants, Fig. 6j,o) and coffee bean-shaped nuclei (Fig. 6o), both characteristic of adult GCTs, were occasionally present.

The molecular signature of the tumours was assessed by IHC for markers associated with human adult GCTs. Marker expression patterns in tumours derived from 12 months of age as compared to 1/19 (5.26%) of the APC2-proficient (hypomorphic Apc only) cohort developing ovarian GCT at 18 months of age (Table 1).

**Table 1** Frequency of GCT formation in 12 and 18-month-old Apc2 experimental genotypes on the background of Apcfl/fl.

| Age (months) | Genotype | Frequency of ovarian GCT |
|--------------|----------|---------------------------|
| 12           | Apc2+/−  | 0/10 (0%)                 |
| 12           | Apc2−/−  | 0/4 (0%)                  |
| 12           | Apc2+/−  | 2*/10 (20%)               |
| 18           | Apc2+/−  | 1/9 (11.1%)               |
| 18           | Apc2−/−  | 3/9 (33.3%)               |
| 18           | Apc2−/−  | 1/6 (16.67%)              |
to 18 month Apc2+/− and Apc2−/− mice were compared with the single GCT which formed in an 18 month Apc2+/+ animal (all animals also carrying the hypomorphic Apc allele, as noted above). In general, the expression patterns of most of the markers examined was similar in the Apc2+/+, Apc2+/− and Apc2−/− tumours (Figs. 7 and 8). Several studies have shown increased FOXL2 protein expression in human GCTs and animal models [59–61], and in agreement with these findings, our GCTs also displayed elevated levels of FOXL2.
expression (Fig. 7, Additional file 6: Fig. S5)a. The tumours were also positive for inhibin-α, which is used in the differential diagnosis of GCTs [62], and which showed focal cytoplasmic staining (Fig. 7). Staining for Ki67, CD34 and cleaved caspase 3 demonstrated the classic hallmarks of proliferation, neovascularization (angiogenesis) and absence of apoptosis respectively, in all GCTs analysed (Fig. 7). Impaired follicular growth in 10-week-old Apc2−/− ovaries was associated with increased apoptosis (Fig. 3c-e) and Foxo1 expression (Fig. 4c). As apoptosis was reduced in the GCTs from aged mice, we analysed FOXO1 expression levels by IHC and observed a reduction in FOXO1 staining in GCT area as compared to granulosa cells of growing follicles (Fig. 8, follicle indicated by black arrow; Additional file 6: Figure S5)b.

To determine whether active canonical WNT signalling was associated with GCT formation, β-catenin staining was carried out. Tumour cells strongly expressed β-catenin in contrast to the expression seen in non-tumour areas (Fig. 8; compare β-catenin staining in tumour area indicated by black arrow with non-tumour area indicated by red arrow). Due to limitation of available tumour samples, qRT-PCR analysis could only be
performed on two WNT signalling target genes (Wif1 and Axin2) using RNA from two Apc2-deficient GCTs, with Apc2-proficient ovaries used as control material. Two independent areas from each tumour were analysed to allow for tumour heterogeneity. Comparison of expression levels demonstrated higher levels of both Wif1 and Axin2 within APC2-deficient tumours (Additional file 6: Figure S5c,d).

Activation of PI3K/AKT signalling via Pten deletion has been shown to enhance GCT development and progression in mouse models driven by WNT signalling activation [63, 64]. However, phospho-AKT (p-AKT), a marker of active PI3K/AKT signalling, was undetectable within our GCTs (Fig. 8). Furthermore, Apc2+/− and Apc2−/− GCTs showed strong PTEN staining, in contrast to no staining in the Apc2+/+ tumour (Fig. 8). This likely explains the lack of pAKT staining in the APC2-deficient tumours. However, the lack of both pAKT and PTEN staining in the Apc2+/+ tumour may result from the hypomorphic APC allele on its own being an insufficiently
strong driver of WNT signalling to activate PI3K/AKT signalling via established cross-talk mechanisms [65].

Estrogen receptor alpha (ERα) also showed differential staining between APC2-deficient tumours compared to the APC2-proficient tumour analysed. Human ovarian GCTs are also characterized by frequent focal staining for estrogen receptor alpha (ERα) (Fig. 8; Additional file 6: Figure S5)e which suggests that APC2 deficiency not only increases the frequency of GCTs in mice which also carry a hypomorphic Apc allele, but also results in tumours with a greater histological and molecular similarity to human GCTs.

**Discussion**

This study has revealed that APC2-deficiency activates WNT signalling in the ovary during early adulthood, which subsequently disrupts ovarian homeostasis and causes subfertility originating from an ovarian defect. Follicle growth was perturbed in APC2-deficient mice secondary to defective response to gonadotrophins, reduced follicular vascularity, downregulation of genes coding for steroidogenic enzymes and upregulation of Foxo1 expression, which contributed to increased apoptosis of granulosa cells in APC2-deficient follicles. At least 20% of APC2-deficient female mice (on the background of a hypomorphic Apc allele) go on to develop WNT-driven GCT as early as 12 months. These tumours recapitulated human adult GCT histology and molecular features.

Our findings highlight the role of APC2 as an important regulator of WNT signalling in the ovary. Although initial studies performed in *Drosophila* and on cell lines to functionally-characterize APC2 demonstrated the presence of β-catenin and AXIN1 binding sites in APC2, which enable it to regulate WNT signalling [22, 23, 26, 66–68], in an in vivo mammalian setting, APC2 function is tissue specific. APC2 loss in the mouse small intestine and liver resulted in activation of WNT signalling but not in the mammary glands [33, 34]. Hence, the functions of APC2 cannot be extrapolated from one mammalian system to another without direct experimentation.

The tumour suppressor role of APC2 protein in ovarian granulosa cell tumour formation has been highlighted here for the first time and the current study provides further evidence of the roles of WNT signalling activation in the pathogenesis of ovarian GCT. These findings build on previous work pointing to this role of WNT signalling in clinical data [17, 19, 20, 69], and in GEMMs [15, 17] but as noted above, given the tissue-specific effects of APC2 knockout, could not have been predicted a priori.

The current findings also extend our knowledge of deleterious effects of WNT signalling activation on ovarian homeostasis and fertility [10, 15–17]. We have shown that reduced ovulation observed in APC2-deficient mice is not caused by defects in ovulation and terminal differentiation of granulosa cells (which happen when WNT signalling is activated in antral follicles), but rather caused by restricted follicular growth and failure to reach the pre-ovulatory stage. This phenotype is similar to previous phenotypes published when WNT signalling was activated in pre-antral follicles [16, 17], implying that APC2 activity is required in growing follicles as early as the pre-antral stage.

Given the constitutive nature of the *Apc2* null allele, both autonomous and non-autonomous mechanisms are expected to contribute to the phenotypes described. Results of the current study have clearly shown the intra-ovarian origin of the subfertility phenotype described in APC2-deficient mice, and that hypomorphic-pituitary regulation of ovarian function is not contributing to the subfertility phenotype. Although the subfertility is caused by increased apoptosis of granulosa cells, a contribution of endothelial cells to the phenotype was evident. Whether the same phenotype could be reproduced if APC2-deletion was targeted exclusively to granulosa cells (e.g. using *Amhr2* or *Cyp19a-cre*) remains unknown, due to the unavailability of an *Apc2* conditional allele. The same applies to GCTs developing in APC2-deficient mice, which – in contrast – displayed enhanced angiogenesis.

It is unlikely that WNT signalling activation is the sole driver of the reported phenotypes and cross talk between WNT signalling and other signalling pathways must also be considered. For example, unlike in early adulthood, FOXO1 expression was absent in APC2-deficient GCT, implying a need to silence FOXO1 and to stop FOXO1-driven granulosa cell apoptosis as a prerequisite for tumourigenesis. It has been previously shown that knocking out *Foxo1/Foxo3* leads to the development of GCT in 20% of female mice [60]. However, the cause of the ‘switch’ from FOXO1 being present and granulosa cell apoptosis to absent FOXO1 with granulosa cell proliferation and tumourigenesis was not identified and needs to be further characterized. The high levels of PTEN in granulosa cells of growing follicles might have contributed to increased apoptosis by inhibiting the translocation of FOXO1 outside the nucleus and thus ensuring FOXO1 activates pro-apoptotic target genes. In addition, high PTEN expression levels found in GCT of APC2-deficient ovaries might be responsible for the late development of tumourigenesis, as previously described in other models [60, 63, 64]. It is thus possible to hypothesize that, similar to previously published models, deleting *Pten* in granulosa cells of APC2-deficient ovaries would lead to rapid tumour development.

This study has caveats. One limitation was that the breeding data available for different genotypes of female *Apc2* mice (*Apc2*+/+, *Apc2*+/−, *Apc2*−/−) represented crossings to males of the corresponding genotype, rather
than to wild type males. Effects of Apc2-gene dosage on male fertility are not yet characterized, with the caveat that male fertility might be affected in APC2-deficient male mice, and could contribute to the delayed pregnancy and reduced litter size observed in APC2-deficient crosses. However, retrieval and counting of ovulated oocytes post-gonadotrophin administration confirmed that APC2-deficient female mice ovulate less and would be expected to give smaller litter size. Impairment of response to gonadotrophin is mediated by overexpression of Lhcgr, which has been recently reported to cause complete infertility in female mice, with histological analysis revealing that follicles failed to progress beyond the pre-antral stage [47]. Over-expression of Lhcgr in APC2-deficient mice most likely occurs due to canonical WNT signalling activation, as a 3.5-fold increase in Lhcgr expression levels has been reported in granulosa cells transduced with constitutively-active β-catenin, in the presence of FSH [46]. In addition, this early elevation of Lhcgr expression might have contributed to GCT development [46]. Another important caveat to this study was the small numbers of aged Apc2−/− mice available for tumour development studies. This was, unfortunately, an unavoidable consequence of the reduced fertility phenotype in these animals.

Conclusions
This study advances our understanding of the role of WNT signalling in ovarian homeostasis and tumourigenesis, and of the role played by APC2 in regulating this pathway. The finding that WNT signalling activation in growing follicles impairs ovulation raises the importance of the assessment of WNT signalling activation in the setting of human female subfertility/infertility. This could provide new insights into the molecular pathogenesis of this condition, and may help in designing new treatment interventions for these patients. Furthermore, our findings extend the list of mutations which cause female subfertility or infertility in early adulthood in mice followed by development of GCT upon aging [15, 17, 47, 60]. It remains to be determined if a similar link exists in humans and, if so, what are the molecular drivers, but APC2 must now be included on the list of candidates which should be investigated in this clinical context. Furthermore, the direct mechanistic link between WNT signalling activation, β-catenin stabilisation and GCT formation warrants further investigation.

Acknowledgements
We thank Professor Hans Clevers for providing us with Apc2−/− mouse, Professor Owen Sansom for critically reviewing the results, Professor Geraint Williams for training and guidance on histopathological assessment of ovaries, Elaine Taylor for assistance with mouse husbandry, Mark Bishop and Matthew Zverev for technical support and genotyping and Derek Scarborough for histologic preparation of tissues.

Authors’ contributions
The research project was designed by NM, TH, MJS and ARC. NM, TH and KRR managed the mouse intercrosses. NM performed all data collection and analysis. The manuscript was drafted by NM and KRR. This manuscript is dedicated to the memory of the late Professor Alan Clarke. All other authors critically reviewed the manuscript and approved the final version submitted.

Funding
This project was funded by Egyptian Ministry of Higher Education (represented by the Egyptian Educational Bureau in London) and Cancer Research UK (ARC Programme grant C1295/A15937).

Availability of data and materials
This study contains no large data sets. The Apc2−/− mouse was provided by Professor Hans Clevers. Please contact Professor Matthew J Smalley (SmalleyMJ@Cardiff.ac.uk) for access to all other materials.

Ethics approval and consent to participate
Patient studies – not applicable, no human subjects involved. Animals studies – all experiments were carried out under the authority of UK Home Office personal and project licences (30/2737 and 30/3279) and according to ARRIVE guidelines and following local ethical review by the Cardiff University Animal Welfare Ethical Review Panel.

Consent for publication
Not applicable, no human subjects involved.
