ABSTRACT

Antimicrobial resistance is an urgent global health challenge in human and veterinary medicine. Wild animals are not directly exposed to clinically relevant antibiotics; however, antibacterial resistance in wild animals has been increasingly reported worldwide in parallel to the situation in human and veterinary medicine. This underlies the complexity of bacterial resistance in wild animals and the possible interspecies transmission between humans, domestic animals, the environment, and wildlife. This review summarizes the current data on expanded-spectrum β-lactamase (ESBL), AmpC β-lactamase, carbapenemase, and colistin resistance genes in Enterobacteriaceae isolates of wildlife origin. The aim of this review is to better understand the important role of wild animals as reservoirs and vectors in the global dissemination of crucial clinical antibacterial resistance. In this regard, continued surveillance is urgently needed worldwide.

Keywords: AmpC; ESBLs; IMP, mcr-1; NDM; Wild birds

INTRODUCTION

Over several decades, antimicrobial resistance has become a global clinical and public health threat against the effective treatment of common infections caused by resistant pathogens, resulting in treatment failure and increased mortality (WHO, 2014). The development of bacterial resistance is a natural evolution of microorganisms, but the widespread use and misuse of antibacterial agents in humans and animals has accelerated this process (WHO, 2014). Furthermore, the increasing frequency of global travel and trade has also contributed to the rapid worldwide spread of antimicrobial resistance (Laxminarayan et al., 2013). Some resistant clones, such as Escherichia coli ST131, Klebsiella pneumoniae ST258 and ST11, and methicillin-resistant Staphylococcus aureus (MRSA) USA 300, which are involved in the spread of resistance to crucially significant antibiotics in human medicine, have been widely disseminated (Lee et al., 2016; Mathers et al., 2015; Nimmo, 2012). Antimicrobial resistance is a complex and multifaceted problem involving humans, animals, and the environment. However, the role of wildlife in the emergence of antibacterial resistance might be underestimated. The first report of antibacterial resistance in wildlife revealed chloramphenicol resistance in E. coli isolates obtained from Japanese wild birds (Sato et al., 1978). Since then, the occurrence of resistant bacteria in wild animals has been increasingly reported within diverse animal species across different geographical areas. In addition, several important antimicrobial resistant pathogens, such as MRSA (Loncaric et al., 2013a; Porro et al., 2014), vancomycin-resistant enterococci (Drobni et al., 2009; Sellin et al., 2000), Salmonella spp. (Lee et al., 2011a), Vibrio cholerae (Aberkane et al., 2015), and Campylobacter spp. (Weis et al., 2016), have been described in wild animals, highlighting the importance and complexity of wildlife, not normally exposed to antibiotics directly, in the transmission of resistant bacteria.

This review gives a brief overview of the emergence and prevalence of expanded-spectrum β-lactamase (ESBL), AmpC β-lactamase, carbapenemase, and colistin resistance genes in Enterobacteriaceae strains from wild animals, all of which have significant public health impact. Furthermore, this review aims to better understand the role of wildlife in the transmission of clinically significant antimicrobial resistance in Enterobacteriaceae.

ESBL-PRODUCING ENTEROBACTERIACEAE FROM WILDLIFE

The global dissemination of ESBL-producing Enterobacteriaceae in human clinics is an urgent problem that poses a serious challenge to the treatment of infectious diseases, particularly the worldwide emergence of CTX-M-15-producing ST131 E. coli.
coli (Alghoribi et al., 2015; Blanco et al., 2013; Hansen et al., 2014; Hussain et al., 2014; Mathers et al., 2015; Platell et al., 2011; Sauget et al., 2016). ESBL-producing Enterobacteriaceae have also been increasingly reported in livestock, companion animals, and food (Aliyu et al., 2016; Braun et al., 2016; Ewers et al., 2010; Hordijk et al., 2013; Michael et al., 2016). The CTX-M-type β-lactamases are the most common ESBLs among Enterobacteriaceae isolates of human and veterinary origin worldwide (Hordijk et al., 2013; Liu et al., 2016a; Pletsch et al., 2017; Wang et al., 2016; Wellington et al., 2013).

Since the first report on ESBL-producing E. coli isolates from wild animals in Portugal in 2006 (Costa et al., 2006), ESBL-producing Enterobacteriaceae of wildlife origin have so far been reported in Europe, Africa, Asia, South America, North America, and Australia (Table 1). Although ESBLs have been found in various Enterobacteriaceae, the most ESBL-producing bacterial pathogens in wild animals are E. coli, followed by K. pneumoniae (Table 1). To date, at least 80 wildlife species have been found to carry ESBL-producing Enterobacteriaceae, most being wild birds (Table 1). Similar to that among isolates from human and veterinary medicine, the CTX-M family is the most prevalent type of ESBL-producing Enterobacteriaceae found in wild animals (Table 1). Both blaCTX-M-1 and blaCTX-M-15 are commonly reported in wild animals and are the most prevalent ESBL genes, followed by blaCTX-M-14, blaCTX-M-2, blaCTX-M-15, and blaCTX-M-22. Other ESBL genes, such as blaCTX-M-2, blaCTX-M-8, blaCTX-M-14, and blaCTX-M-22, have also been detected, though infrequently (Table 1). Significant geographical differences have been observed in the occurrence of CTX-M enzymes. As summarized in Table 1, CTX-M-15 is the only reported CTX-M-type β-lactamase in Africa to date, and is the most common CTX-M-type enzyme reported in Bangladesh. In Canada and the US, CTX-M-14 is dominant, followed by CTX-M-15. Diversity in CTX-M β-lactamases has been reported in European countries, with the predominance of CTX-M-1 and CTX-M-15. Interestingly, CTX-M-15 is also reported to be the most common CTX-M enzyme in Francisella’s gulls (Leucophaeus pipixcan) in northern Chile (Báez et al., 2015), although CTX-M-1 was previously reported to be dominant in the same gull species in central Chile (Hernandez et al., 2013). Báez et al. (2015) hypothesized that, based on their migratory habits, Francisella’s gulls from the north acquired resistant CTX-M-15-producing ST131 and ST10 E. coli clones, which are highly prevalent in humans in the US and Canada but scarce in Chile. However, this hypothesis, though possible, needs further investigation.

In addition to CTX-M enzymes, SHV and TEM enzymes have also been reported in wildlife, especially SHV-12 and TEM-52, which accords with that found in ESBL-producing isolates from humans, livestock, and companion animals (Table 1) (Blanco et al., 2013; Carattoli et al., 2005; Hordijk et al., 2013; Michael et al., 2016; Smet et al., 2010). For example, SHV-12 has been frequently detected in wildlife in Spain (Alcalà et al., 2016; Gonçalves et al., 2012), and is highly prevalent in ESBL-producing E. coli obtained from 8- to 16-month-old healthy children in northern Spain (Fernández-Reyes et al., 2014) and in raw poultry meat from southern Spain (Egea et al., 2012), as well as from hospitals (Blanco et al., 2013). Other SHV-type enzymes, such as SHV-102, SHV-1, SHV-2, and SHV-5, and TEM-type enzymes, such as TEM-19, TEM-40, TEM-176, and TEM-20, have also been sporadically reported in wild animals (Table 1).

More than 170 different sequence types (STs) have been identified in ESBL-producing E. coli isolates of wildlife origin (Table 1). Among them, ST131 is the most commonly detected clone. The dominant ST131 clone identified in wild animals, which has been frequently described in humans, companion animals, food products, and the environment, is involved in the international dissemination of blaCTX-M-15 and blaCTX-M-14 (Alghoribi et al., 2015; Bogaerts et al., 2015; Ewers et al., 2010; Hu et al., 2013; Hussain et al., 2014; Kawamura et al., 2014; Kim et al., 2017; Mathers et al., 2015). Additionally, other STs described in wild animals, such as ST10, ST68, ST405, ST410, and ST648, have also been reported in various sources and are responsible for the intercontinental distribution of CTX-M (Fischer et al., 2014, 2017; Hansen et al., 2014; Hu et al., 2013; Liu et al., 2016a; Müller et al., 2016; Su et al., 2016; Wang et al., 2016). However, some STs found in wildlife, such as ST1340, ST1646, ST2687, ST3018, and ST3056, have been identified as new types and have not yet been reported in human or veterinary isolates (Bonnedahl et al., 2010; Hasan et al., 2014; Jamborova et al., 2015).

As for ESBL-producing K. pneumoniae, limited studies are currently available on the clonal group of K. pneumoniae from wildlife (Table 1). Loncaric et al. (2016) found an SHV-11-encoding K. pneumoniae strain from moufflon (Ovis orientalis musimon) in Austria belonging to the epidemic clone ST11, which is associated with carbapenemase (Hu et al., 2016; Kim et al., 2013; Lee et al., 2016; Voulgari et al., 2016) and ESBL in humans worldwide (Hu et al., 2016; Lee et al., 2011b; Lu et al., 2016; Sennati et al., 2012), and previously described in companion animals and Eurasian beaver (Castor fiber) (Donati et al., 2014; Pilo et al., 2015). In Algeria, all 17 blaCTX-M-15-bearing K. pneumoniae isolates found in wild bears and Barbary macaques belong to ST584, which has also been detected in silver gulls as carriers of carbapenemase IMP-4 in Australia (Dolejska et al., 2016) as well as in human in Brazil (http://bigdb.pasteur.fr/klebsiella/klebsiella.html). Successful clones found in humans and domestic and wild animals indicate possible interspecies transmission of ESBL-producing isolates. However, horizontal transfer mediated by mobile elements, such as insertion sequences and plasmids, is also one of the main methods for ESBL dissemination worldwide (Carattoli, 2013; Partridge, 2015). Only limited (mostly European) studies are available on ESBL-encoding plasmids in wild animals (Table 1). For example, blaCTX-M-15 is reportedly associated with IncF plasmids (mostly multiple replicons containing IncFIA and IncFIB) and IncF1 (Guenther et al., 2010a; Loncaric et al., 2016; Poirel et al., 2012; Tausova et al., 2012; Veldman et al., 2013), which agrees with previous research involving CTX-M-15-producing Enterobacteriaceae obtained from the environment, healthy cattle, and humans.

* TEM and SHV genotype not specified.  
* Plasmid replicons performed on original isolates are not listed in Table 1; NT, plasmid replicons not determined by PCR-based replicon typing.  
* 50 of 129 ESBL-producing isolates were randomly selected for further genotype and MLST analysis.  
* 20 of 55 ESBL-producing E. coli isolates were selected for MLST analysis.  
* Numbers of bla\_CTX-M-1, bla\_CTX-M-14, bla\_CTX-M-15, and bla\_CTX-M-79 were not specified; 27 of 154 ESBL-producing isolates were selected for MLST analysis.  
* Numbers of bla\_TEM and bla\_SHV, including bla\_TEM-1, bla\_TEM-2, and bla\_SHV-1, which were not true ESBLs.
(Zurfluh et al., 2015). IncHI2 plasmids have also been reported as carriers of \textit{bla}_{CTX-M-15} in humans (Harrois et al., 2014; Nilsen et al., 2013), companion animals (Haenni et al., 2016), pigs (Tamang et al., 2015), and wild birds (Veldman et al., 2013). Though rare, IncI2 plasmid has also been described with \textit{bla}_{CTX-M-15} in the lesser black-backed gull from the Netherlands (Veldman et al., 2013) and identified in a chicken \textit{E. coli} strain in China (Liu et al., 2015). In \textit{Enterobacteriaceae} of human and veterinary origin, \textit{bla}_{CTX-M-1} has been frequently found associated with IncN and IncI plasmids (Carattoli, 2009; Jakobsen et al., 2015; Madec et al., 2015). Interestingly, \textit{bla}_{CTX-M-1} has been mainly located on IncI1 plasmids in wildlife in Europe as well (Literak et al., 2010a, b; Loncaric et al., 2013b; Veldman et al., 2013). However, IncN, IncF, and IncHI1 plasmids have also been reported as carriers of \textit{bla}_{CTX-M-1} (Literak et al., 2010a; Loncaric et al., 2013b; Veldman et al., 2013). Furthermore, IncI1 plasmids are also carriers of other ESBL genes in wild animals, such as \textit{bla}_{TEM-3}, \textit{bla}_{SHV-12}, and \textit{bla}_{TEM-52} (Poirel et al., 2012; Veldman et al., 2013). Similarly, IncF plasmids are also reported to be associated with \textit{bla}_{CTX-M-3}, \textit{bla}_{CTX-M-5}, \textit{bla}_{CTX-M-14}, \textit{bla}_{CTX-M-27}, \textit{bla}_{CTX-M-32}, and \textit{bla}_{SHV-12} in wildlife (Guenthner et al., 2010b; Poirel et al., 2012; Tausova et al., 2012; Veldman et al., 2013). The narrow-host-range plasmid IncN has been found to carry several ESBL genes, namely \textit{bla}_{TEM-12β}, \textit{bla}_{TEM-2β}, \textit{bla}_{TEM-17β}, and \textit{bla}_{SHV-12} in \textit{E. coli} (Poirel et al., 2012; Veldman et al., 2013), as previously reported in humans, companion animals, broiler chickens, and retail meat (Bortolaia et al., 2014; Hansen et al., 2016; Hiki et al., 2013; So et al., 2012; Vogt et al. 2014). Thus far, the IncN/C plasmid, a major carrier of \textit{bla}_{CMY-2}, has not yet been identified in wild animals. The absence of \textit{bla}_{CMY-2}-bearing IncN/C plasmids could simply reflect the limited studies on the characterization of \textit{bla}_{CMY-2}-carrying plasmids in wildlife, or might indicate that \textit{bla}_{CMY-2}-harbouring IncN/C plasmids are more successful among wildlife.

In addition to CMY-2, DHA-type AmpC \textit{β}-lactamases have also been detected in \textit{K. pneumoniae} from moufflons (\textit{Ovis orientalis musimon}) in Austria, \textit{E. coli} from hill mynth (\textit{Gracula religiosa}) in Saudi Arabia, and \textit{K. pneumoniae} ST11 isolates from Eurasian beaver (\textit{Castor fiber}) in Switzerland (Hassan & Shobrak, 2015; Loncaric et al., 2016; Pilo et al., 2015). FOX-5 encoded by an IncA/C plasmid has been obtained from \textit{K. pneumoniae} isolates in the US (Poirel et al., 2012). Furthermore, a novel variant of the ACT AmpC \textit{β}-lactamase gene has been identified in an \textit{Enterobacter cloacae} strain originating from glaucous gull (\textit{Larus hyperboreus}) in Arctic Svalbard, Norway (Literak et al., 2014).

**CARBAPENEMASE-PRODUCING ENTEROBACTERIACEAE FROM WILDLIFE**

Carbapenemase-producing \textit{Enterobacteriaceae} isolates pose an urgent public health threat. New Delhi metallo-\textit{β}-lactamase (NDM), as one of the most widespread carbapenemases, has been increasingly reported in human clinics, foods, domestic animals, and the environment worldwide (Abdallah et al., 2015; Chandran et al., 2014; He et al., 2017; Kumaarasamy et al., 2010; Lee et al., 2016; Qin et al., 2014; Tolemann et al., 2015; Yaici et al., 2016; Yong et al., 2009).

The first reported carbapenemase-producing bacteria in wild animals were isolated from black kites (\textit{Milvus migrans}) in Germany (Fischer et al., 2013). Among 184 cefotaxime-resistant \textit{Salmonella} spp. isolates, only one \textit{Salmonella

Corvallis isolate belonging to ST1541 has shown reduced susceptibility to carbapenem, and carries the carbapenemase gene \( \text{bla}_{\text{NDM-1}} \) located on ~180 kb IncA/C conjugative plasmid pRH-1738 (Fischer et al., 2013). The broad-host-range IncA/C plasmids are among the most predominant plasmids associated with \( \text{bla}_{\text{NDM-1}} \) in humans (Carattoli, 2013). Fischer et al. (2013) supposed that the \( \text{bla}_{\text{NDM-1}} \)-bearing Salmonella Corvallis isolate might have originated from non-European countries and was transferred to Germany through the black kite migratory route, since Salmonella Corvallis was prevalent in South-East Asia and was emerging in North Africa and Nigeria, rather than in European countries. The complete sequence of plasmid pRH-1738 further confirms this hypothesis. Plasmid pRH-1738 exhibited high relatedness with plasmid pMR0211 obtained from human Providencia stuartii isolate in Afghanistan, but showed distinct differences from other sequenced NDM-1-IncA/C plasmids from Western countries (Villa et al., 2015).

In addition, fosfomycin resistance gene \( \text{fosA3} \), which has been rarely detected in Europe but is prevalent among CTX-M-encoding \( \text{E. coli} \) and \( \text{K. pneumoniae} \) isolates in Asia (i.e., China, Japan, and South Korea), has also been identified on NDM-1-producing plasmid pRH-1738. \( \text{bla}_{\text{NDM-1}} \) transferred with \( \text{fosA3} \) on IncA/C plasmid has only been described in clinical \( \text{E. coli} \) and Citrobacter freundii isolates in China (Qin et al., 2014). Taken together, these findings suggest that the origin of this plasmid might be in the Asiatic region.

Large-scale transmission of IMP-producing bacteria into wildlife was first reported in 2015. In total, 120 carbapenemase-producing Enterobacteriaceae of 10 species were observed from silver gulls in Australia, mainly \( \text{E. coli} \) (\( \text{n}=85 \)), carrying \( \text{bla}_{\text{IMP-4}} \), \( \text{bla}_{\text{IMP-2B}} \), or \( \text{bla}_{\text{IMP-2E}} \) (Dolejska et al., 2016). The \( \text{bla}_{\text{IMP-4}} \) gene has been found in 116 isolates, and is the most commonly detected gene among carbapenemase-producing Enterobacteriaceae isolates in human clinics in Australia (Bell et al., 2016; Sidjabat et al., 2015). \( \text{bla}_{\text{IMP-4}} \) in gulls is carried by various conjugative plasmids, mostly IncHI2-N plasmid type, followed by IncA/C plasmids, as well as IncL/M and Inc1, and is associated with a class 1 integron-containing \( \text{bla}_{\text{IMP-4}}-\text{qacG-aacA4-catB3} \) array in most positive strains (Dolejska et al., 2016). The same array carried by IncA/C and IncL/M plasmids is also reportedly responsible for the dissemination of \( \text{bla}_{\text{IMP-4}} \) in clinical isolates in Australia (Espedido et al., 2008), and by the IncHI2 plasmid in Salmonella Typhimurium from a cat in Australia (Abraham et al., 2016). Furthermore, 19 different STs have been detected in IMP-4-producing \( \text{E. coli} \) isolates, including five prevalent lineages (ST216, ST58, ST354, ST167, and ST224), in which ST58, ST354, and ST167 are clinically relevant clone lineages (Ben Sallem et al., 2015; Fernández et al., 2014; Huang et al., 2016).

Although carbapenem resistance reported in wild animals is rare, the emergence of NDM-1 and IMP carbapenemases in wild birds is of concern.

**COLISTIN RESISTANCE GENE mcr-1 IN ENTEROBACTERIACEAE FROM WILDLIFE**

Colistin is widely applied in food-producing animals and is currently used as the last resort for treating infections caused by multi-resistant gram-negative bacteria (Kaye et al., 2016). Since the first identification of the plasmid-mediated colistin resistance gene \( \text{mcr-1} \) in China in 2015 (Liu et al., 2016b), it has been identified in Enterobacteriaceae isolates from food-producing animals, companion animals, food products, the environment, and humans worldwide (Anjum et al., 2016; Doumith et al., 2016; Hasman et al., 2015; McGann et al., 2016; Xavier et al., 2016; Zhang et al., 2016; Zurfluh et al., 2016).

The role of wild birds as reservoirs and vectors for the global distribution of \( \text{mcr-1} \) should be considered. Recently, \( \text{mcr-1} \) was described in an \( \text{E. coli} \) strain isolated from European herring gull (Larus argentatus) feces collected from the Kaunas (Lithuania) city dump (Ruzauskas & Vaskeviucute, 2016). However, the emergence of \( \text{mcr-1} \) in wildlife could be traced back to \( \text{E. coli} \) strains isolated in 2012 (Liakopoulos et al., 2016). Five extended-spectrum cephalosporin-resistant \( \text{E. coli} \) isolates obtained from kelp gulls in Ushuaia, Argentina in 2012 were found to carry \( \text{mcr-1} \) and \( \text{bla}_{\text{CTX-M-2}} \) (\( \text{n}=1 \)) and \( \text{bla}_{\text{CTX-M-4}} \) (\( \text{n}=4 \)) and exhibited elevated colistin MICs (4–8 mg/L). The \( \text{mcr-1} \) gene was located on a ~57 kb IncI2 plasmid without \( \text{bla}_{\text{CTX-M}} \) in all five isolates. IncI2 plasmids, which have been detected in \( \text{E. coli} \) and Salmonella isolates from food, food-producing animals, and humans in China, Great Britain, the US, Venezuela, and Denmark, have been reported to be associated with the transmission of \( \text{mcr-1} \) (Anjum et al., 2016; Delgado-Blas et al., 2016; Doumith et al., 2016; Hasman et al., 2015; Meinersmann et al., 2016; Yang et al., 2016). Notably, four \( \text{mcr-1} \)-carrying isolates, which belong to ST744, have been previously described in Denmark and carry the \( \text{mcr-1} \)-bearing IncI2 plasmid (Hasman et al., 2015; Liakopoulos et al., 2016).

**CONCLUSIONS**

Clinically relevant resistance, such as ESBL, AmpC cephalosporinase, carbapenemase, and colistin resistance, has been detected in wild animals, particularly wild birds, from distinct geographical areas. Thus, wild animals could serve as important reservoirs of resistant bacteria. Although the origin of bacterial resistance genes in wild animals remains unclear, as wildlife are not exposed to antibiotics directly, contact with sewage or animal manure might be one possibility (Wellington et al., 2013). Additionally, the potential of wild animals as vectors of resistant bacteria or genetic determinants should not be underestimated. Wildlife, especially migratory birds with their instinctive mobility, can carry resistant bacteria over long distances, even between continents; thus, this might be a new transmission route and partly responsible for the global dissemination of bacterial resistance. Contamination of food or water by wildlife is recognized as an important risk factor for the transmission of antimicrobial resistance or pathogens to food animals and humans (Greig et al., 2015).

Wild animals might play a vital role in the worldwide spread of clinically relevant pathogens or resistance genes. Pandemic ESBL-producing \( \text{E. coli} \) clones or plasmids shared by humans, domestic animals, and wildlife further strengthen this hypothesis. Thus, continued surveillance of multi-resistant bacteria in wild animals is warranted.
