ABSTRACT
The objective of this study was to modify suede leather by coating Ag nanoparticles which synthesized with an extract from green betel leaf. The success of suede leather modification with silver nanoparticles was analyzed by FTIR spectrophotometer, SEM tool, and antibacterial activity test. Characteristic of Ag nanoparticles was analyzed through using a UV-Vis spectrophotometer. The stages of experimental research carried out where the extraction of betel leaves, preparation of Ag nanoparticles with betel leaf extract using precursors of silver nitrate solution, characterization of Ag nanoparticles with Ultra Violet-Visible spectrophotometer, modification of suede leather with silver nanoparticles, characterization of suede leather without modification with FTIR spectrophotometer, SEM observations, and antibacterial activity tests with diffusion techniques. The results showed that betel leaf extract could change silver nitrate salt to Ag nanoparticles as indicated by UV-Vis’ absorption which peaked at 259 nm and 456 nm. The FTIR spectrum showed that silver nanoparticles were successfully introduced into suede leather with the interaction between -OH free and -C = O free with Ag nanoparticles. SEM photos showed that Ag nanoparticles successfully layered the surface of suede leather tissue and the shape of the silver nanoparticles was spherical. Suede leather with the addition of silver nanoparticles had the best ability to cause the death of E. coli bacteria, outperforming leather without modification by 1.8 times and silver nanoparticles in incubation for 36 hours by 1.3 times. The incubation time significantly affected the inhibition in the growth of S. aureus bacteria by suede leather samples.

Keywords: Antibacterial Activity, Piper Betle, Suede Leather, Silver Nanoparticle, SEM.

INTRODUCTION
Nanotechnology is the science and engineering of the creation of material and functional structures on a nanometer scale.¹,² One of the most popular developments in nanotechnology is the synthesis of silver nanoparticles. The silver nanoparticle is a new anti-microbial agent to the growth of microorganisms.³ Silver nanoparticles as antimicrobials are used in various industrial fields such as electronics, medicine, optics, cosmetics, textiles⁴,⁵ and leather.⁶,⁷ Many ways to synthesize nanoparticles are through physical, chemical and biological methods. One of them is to reduce silver ions using plant extracts.⁸,⁹ The nanomaterial synthesis is biologically called biosynthetic. Biosynthetic nanoparticles involve compounds from plants such as flavonoids.⁸ Flavonoids can change salts to nanoparticles. This is caused by the functional groups in flavonoids. Flavonoids are a large group of polyphenol compounds that have groups classes: anthocyanins, isoflavonoids, flavonols, and flavones. Flavonoids contain several functional groups that play a role in the formation of nanoparticles. There is a postulate that tautomeric transformation from flavonoids from enol to keto forms can release reactive hydrogen atoms which can reduce metal ions to nanoparticles. Some types of plants contain antioxidant compounds such as phenolics, terpenoids, flavonoids and tannins. Banana peel extract could be used as an agent in producing nanoparticles.¹⁰ Phenolic compounds have the characteristic of having at least one aromatic ring (C6) with
ENHANCEMENT OF ANTIBACTERIAL ACTIVITY OF SUEDE  

E. Rohaeti et al.

Phenolic compounds have antioxidant properties because they have a strong tendency to reduce metals. Phenolic compounds' ability to reduce metals exists because they have high nucleophilic characters from aromatic rings. This decade, researchers are finding alternative ways for the development of cost-effective procedures, high reproducibility, stable procedures, and metal nanoparticles produced using resource-based materials.

Green betel leaves (Piper betle) contain phenols, tannins, sterols, flavonoids, and antioxidant compounds in large quantities. This study synthesizes silver nanoparticles using betel leaf extract as a bioreductor and adding of PVA to prevent agglomeration of the Ag nanoparticles produced. Previous researches have revealed the use of sodium citrate in producing nanoparticles and the use of betel leaf extract in the preparation of silver nanoparticles. The silver nanoparticles and the gold nanoparticles have successfully produced by green synthesis using pine gum. However, in those studies, did not add any stabilizers in the synthesis process of nanoparticles. In our research, the addition of stabilizers in the form of PVA in producing nanoparticles has been tried. This research was carried out because it had never been applied to suede leather before. The cotton fabric and leather products showed excellent antibacterial activity against Brevibacterium linens. The study aimed to determine the effectiveness of silver nanoparticles with bioreductors from betel leaf extract as anti-bacterial on suede leather.

EXPERIMENTAL

Materials
The suede leather was purchased from the leather industry in Yogyakarta, Indonesia. Salt of silver nitrate, PVA liquid, C\textsubscript{2}H\textsubscript{5}OH, C\textsubscript{3}H\textsubscript{6}O, and hexadecyltrimethoxysilane was purchased as commercial products. Nutrient Agar (NA) and Nutrient Broth (NB) were purchase from Oxoid. Staphylococcus aureus ATCC 25923 and Escherichia coli 32518 were obtained from the collection of Faculty of Medicine, Gadjah Mada University Yogyakarta, Indonesia. The study was conducted in consecutive stages as follows: extraction of Piper betle leaf, preparation of silver nanoparticle, deposition of silver nanoparticles on suede leather, characterization using UV-Vis, FTIR, SEM, and antibacterial activity testing.

Methods
Preparation of Silver Nanoparticle (Ag)
As much as 100 mL distilled water was put into a glass beaker that has a volume of 500 mL to wash 20 grams of green betel leaves. Then the boiling process was carried out for 20 minutes to obtain an extract of green betel leaf. This extract was then filtered using Whatman no. 42 at room temperature. To about 1 mL of extract, 40 mL of silver nitrate solution 1.10^{-3} M was added. The mixture was left for about 2 hours to react and then 12 mL of 1% PVA solution was added while stirring for another 2 hours. Then, the solution was left for 4 days to produce colloidal silver nanoparticles. The colloid was then analyzed by using a spectrophotometer of Ultra Violet-Visible.

Deposition of Ag Nanoparticles on Leather Fiber (Leather + Ag/S1)
The suede leather was prepared so that it was 5 cm x 5 cm in size, then was washed with acetone for 30 minutes and rinsed thoroughly in non-ion distilled water for about 30 minutes and finally dried using a hairdryer. After, the suede leather was soaked in silver nanoparticles colloid, rotated using a shaker at 153 rpm for 24 hours and left to dry at room temperature.

Test of Antibacterial Activity
The capability of suede leather in inhibiting the growth of bacteria was analyzed by measuring of inhibition zone. The diffusion method was conducted in determining the antibacterial activity of suede leather. The bacteria growth was prepared in media such as NA and NB. As much as 14 gram of NA was dissolved in 500 mL of distilled water and 1.3 gram of NB in 250 mL of distilled water. Each sample of suede leather was prepared with a diameter of 6 mm, then put in the petri dish and left to stand in an oven with a temperature of 25°C for 24 hours. The sample was then observed in an inhibition zone for up to 72
hours. Data of measurement of clear zone diameter on leather against *Staphylococcus aureus* and *Escherichia coli* were analyzed by statistic test using IBM SPSS Statistics 25.10

**Analysis of UV-Vis**
The analysis of UV-Vis was conducted to study the success of the formation of Ag nanoparticles by green synthesis using betel leaf extract. The change in absorption peak at certain wavelengths showed the success of silver nanoparticles formation.5,10,14

**Analysis of FTIR**
The analysis using an FTIR spectrophotometer was conducted to analyze the functional groups of leather before and after the modification with Ag nanoparticles synthesized with *piper betle* leaf extract.

**Observation of Morphology by using SEM**
SEM analysis was done to observe the image of Ag nanoparticles in the matrix of leather suede. Observations were carried out at 2000 times and 5000 times magnification, respectively.

**RESULTS AND DISCUSSION**

**The Success of Forming Silver Nanoparticles using Betel Leaf Extract**
The silver nitrate solution shows maximum absorbance at 61 nm whereas silver nanoparticle colloids show maximum absorbance at 259 nm and 456 nm (Fig.-1). The presence of two new absorption peaks in the UV-Vis spectrum of silver nanoparticle colloids shows the success of betel leaf extract in converting silver ions to silver nanoparticles. The functional groups -OH of flavonoids in leaf extract can reduce silver ions.17 Functional groups of tannin components manipulate actively in changing Ag⁺ to Ag₀ in colloidal formation.18 Flavonoids and tannins are large compounds in betel leaf.19,20

**Fig.-1: The Spectrum of UV-Vis of Nitrate Solution (a) and Silver Nanoparticle (b)**
The Difference of Antibacterial Activity on The Suede Leather in Preventing the Life of *Staphylococcus aureus* and *Escherichia coli*

Table-1 shows that the three types of samples, namely silver nanoparticle, leather, and leather + nanoAg all have significance below 0.05. This means that the three samples have significantly different abilities to prevent the life of both *Staphylococcus aureus* and *Escherichia coli* bacteria. The difference in inhibition zone between 2 types of samples can be seen in Table-2.

Table-1: ANOVA Test: The Effect of Type of Sample and Incubation Time on The Inhibition Ability toward *S. aureus* and *E. coli*

| Source of data          | Sum  | Df  | Average | F        | Sig. |
|-------------------------|------|-----|---------|----------|------|
| Corrected model         | 2.277| 2   | 1.138   | 16.559   | 0.000|
| Intercept               | 44.743| 1   | 44.743  | 650.825  | 0.000|
| VAR000001               | 2.277| 2   | 1.138   | 16.559   | 0.000|

Table-2: Interpretation of The Result of LSD Test Between Product Types against *Staphylococcus aureus* and *Escherichia coli*

| Type of Product | Conclusion | S.aureus | E.coli |
|-----------------|------------|----------|--------|
| Ag - S0         | Significant| Significant| Significant|
| Ag - S1         | Not significant| Significant| Significant|
| S0 – Ag         | Significant| Significant| Significant|
| S0 - S1         | Significant| Significant| Significant|
| S1 – Ag         | Not significant| Significant| Significant|
| S1 - S0         | Significant| Significant| Significant|

Table-2 shows that between the silver nanoparticle sample and suede leather after modification with silver nanoparticle samples showed that the inhibiting ability was significantly different against the two types of bacteria. Between the two types of samples, the silver nanoparticle sample and suede leather after modification with silver nanoparticles had the same ability to inhibit *S. aureus* bacteria and while the inhibiting ability was significantly different against *E. coli*. In other words, gram-negative bacteria and gram-positive bacteria can be inhibited by silver nanoparticles and suede leather after modification with the silver nanoparticle. However, suede leather after modification with silver nanoparticles has higher antibacterial activity toward *E. coli* than toward *S. aureus*. This can be caused by gram-negative bacteria having an outer cell wall consisting of lipopolysaccharide and thin cell walls. The functional groups -NH and -C=O bound to the silver in modified leather structure will interact with the chemical functional group on the membrane via covalent bonds to produce clusters that inhibit cell respiration. Thus, the use of extracts from green betel leaf is effectively embroiled in antibacterial activity and is also used in the production of silver nanoparticles. This is reinforced by data that organic molecules such as terpenoids, alcohols, ketones, aldehydes and carboxylic acids around the nanoparticles.

The Effect of Incubation Time on Antibacterial Activity of Leather toward *Staphylococcus aureus* and *Escherichia coli*

Based on Fig.-2(a) and 2(b), it can be concluded that at increased incubation times, the antibacterial activity of silver nanoparticles, suede leather, and suede leather after modification with silver nanoparticles shows a fluctuating value. Leather without modification showed the highest inhibition zone compared to the leather after modification with silver nanoparticles and silver nanoparticles in preventing the life of *S. aureus* bacteria. This can be caused by the existing composition of various types of proteins.
with functional groups –NH and –COO in leather. The existence of these functional groups can interact with the chemical compounds that make up the wall of the membrane cell of the S. aureus bacteria, resulting in the lysis and bacterial cell death. \(^\text{20}\) However, all three samples show antibacterial activity against S. aureus. Fig.-2(b) shows different results in which leather after modification with silver nanoparticles has the best ability to inhibit E. coli bacteria. This can be caused by the interaction of Ag nanoparticles with the wall of the membrane cell of E. coli bacteria. The resulting interaction can cause E. coli bacterial cell death. The results of the statistical analysis as shown in Table-3 reinforce the results of the graph.

![Fig.-2: The Inhibition Zone of Ag Nanoparticles, Leather, and Leather + Ag Nanoparticles against S. aureus (a) and E. coli (b)](image)

| Type of Sample | Value of Significance | Conclusion |
|----------------|-----------------------|------------|
| S. aureus      |                       |            |
| Ag             | 0.020                 | Difference |
| S0             | 0.044                 | Difference |
| S1             | 0.001                 | Difference |
| E. coli        |                       |            |
| Ag             | 0.868                 | No difference |
| S0             | 0.455                 | No difference |
| S1             | 0.487                 | No difference |

### The Functional Group of Leather

The functional groups of leather with and without the addition of silver nanoparticles were determined by using the FTIR spectrophotometer. Characterization of functional groups on leather before and after modification with silver nanoparticles from a solution of silver nitrate salt using a reducing agent of betel leaf extract to study deposit process of nanoparticle on suede leather. Fig.-3(a) and 3(b) show the FTIR spectrum of leather and leather with addition silver nanoparticles. There appears to be a shift in wavenumbers in the FTIR spectrum of the leather with and without the addition of Ag nanoparticles. The leather without the addition of Ag nanoparticles shows the absorption of -OH group at \(\lambda\ 3294.41\ \text{cm}^{-1}\) with a broad and strong band. Absorption of the aliphatic C-H group at \(\lambda\ 2923.78\ \text{cm}^{-1}\). Uptake of C = O group with a sharp peak at \(\lambda\ 1632.88\ \text{cm}^{-1}\), while at \(\lambda\ 1175.01\ \text{cm}^{-1}\); 1084.37 cm\(^{-1}\) and 1031.70 cm\(^{-1}\) indicates the absorption peak of C-O group. The FTIR spectrum of the leather with the addition of Ag nanoparticles prepared by reducing the betel leaf shows a shift in wavenumber in the -OH group, C-H group, C = O and C-O groups with wave numbers 3272.65 cm\(^{-1}\), 2923.86 cm\(^{-1}\), 1632.22 cm\(^{-1}\), 1083.68 cm\(^{-1}\), and 1031.07 cm\(^{-1}\) respectively. In addition to the shift in wavenumber, it also indicates a change in the amount of absorbance. Modified leather with silver nanoparticles shows a decrease in absorbance especially in the absorption of -OH groups and -C = O groups. This shows that the modification process with silver nanoparticles causes the -OH group and the -C = O group to interact with silver nanoparticles. Consequently, free -OH uptake and -C = O are free to decrease.
Thus, it could be concluded that the process of modification with silver nanoparticles on suede leather was successfully carried out. However, qualitatively the addition of silver nanoparticles does not change the type of functional group from the leather sample. This is by previous researches, that the addition of Ag nanoparticles does not change functional groups of textiles sample.\(^1\)

The Morphological Observation of Leather
SEM observation was intended to see the morphology of silver nanoparticles on the skin using extract reduced from the plant (betel leaf). The results of observations of SEM on grain surfaces with a magnification of 2000x, 5000x, control leather (untreated), and modified leather with silver nanoparticles using reductant betel leaves can be seen in Fig.-4. Fig.-4(a) shows the grain surface of leather (without treatment) with sheet-like shapes.
with the results of previous researches that Ag nanoparticles produced by using plant waste material showed spherical shapes.\(^\text{16}\) Other than that, this result is in line with previous research, namely the deposit of silver nanoparticles on cellulose from rice washing water.\(^\text{22}\) Interaction between suede leather and silver nanoparticle alleged to be chemical adsorption, i.e. via chemical bonding (covalent bond) among –NH, –COOH, -NHCOO- and Ag.\(^\text{23}\) Although in this research, PVA has been used as a stabilizer for the size of silver nanoparticles produced, however, the size of nanoparticles deposited on the surface of suede leather is not uniform. To increase the size uniformity of nanoparticles that cover the surface of the suede leather can be done by adding surfactants such as the PEG compound. The addition of PEG6000 as a surfactant in the synthesis of zink oxide nanoparticles can effect the size and nature of the nanoparticles produced.\(^\text{24}\) The success of depositing silver nanoparticles on the surface of suede leather is demonstrated by the results of observations with the SEM tool. Therefore the antibacterial activity of suede leather can be caused by the addition of silver nanoparticles. As revealed in previous studies, that silver nanoparticles exhibit antibacterial activity against odors and infections caused by bacteria.\(^\text{25}\)

**CONCLUSION**

Betel leaf extract was successfully used in the synthesis of colloid of Ag nanoparticles with precursors of silver nitrate solution as showed by the existence of absorption bands at 259 nm and 456 nm from the Ultra Violet - Visible spectrum of colloidal Ag nanoparticles. The FTIR spectrum showed that silver nanoparticles were successfully deposited in suede leather with a decrease in the absorption intensity of free -OH and -C=O free from the leather after being modified with silver nanoparticles. SEM photos revealed that the silver nanoparticles were spherical, white in color, and spread throughout the suede leather tissue. The three samples, namely silver nanoparticles, suede leather, and suede leather with the addition of silver nanoparticles had significantly different ability levels to inhibit growth against \textit{S. aureus} and \textit{E. coli} bacteria. The incubation time also significantly affected the inhibition zone of leather samples against the growth of \textit{Staphylococcus aureus} bacteria. SEM photos show that silver nanoparticles were successfully deposited in suede leather.
