Asymptotics for the survival probability
in a killed branching random walk

This version: February 15, 2010

Summary. Consider a discrete-time one-dimensional supercritical branching random walk. We study the probability that there exists an infinite ray in the branching random walk that always lies above the line of slope $\gamma - \varepsilon$, where $\gamma$ denotes the asymptotic speed of the right-most position in the branching random walk. Under mild general assumptions upon the distribution of the branching random walk, we prove that when $\varepsilon \to 0$, this probability decays like $\exp\{-\frac{\beta + o(1)}{\varepsilon^{1/2}}\}$, where $\beta$ is a positive constant depending on the distribution of the branching random walk. In the special case of i.i.d. Bernoulli($p$) random variables (with $0 < p < \frac{1}{2}$) assigned on a rooted binary tree, this answers an open question of Robin Pemantle, see [19].

Keywords. Branching random walk, survival probability, maximal displacement.

2000 Mathematics Subject Classification. 60J80.

1 Introduction

We consider a one-dimensional branching random walk in discrete time. Before introducing the model and the problem, we start with an example, borrowed from Pemantle [19], in the study of binary search trees.
Example 1.1 Let $T_{bs}$ be a binary tree ("bs" for binary search), rooted at $e$. Let $(Y(x), x \in T_{bs})$ be a collection, indexed by the vertices of the tree, of i.i.d. Bernoulli random variables with mean $p \in (0, \frac{1}{2})$. For any vertex $x \in T_{bs} \setminus \{e\}$, let $[e, x]$ denote the shortest path connecting $e$ with $x$, and let $[e, x] := [e, x] \setminus \{e\}$. We define

$$U_{bs}(x) := \sum_{v \in [e, x]} Y(v), \quad x \in T_{bs} \setminus \{e\},$$

and $U_{bs}(e) := 0$. Then $(U_{bs}(x), x \in T_{bs})$ is a binary branching Bernoulli random walk. It is known (Kingman [14], Hammersley [8], Biggins [2]) that

$$\lim_{n \to \infty} \frac{1}{n} \max_{|x| = n} U_{bs}(x) = \gamma_{bs}, \quad \text{a.s.,}$$

where the constant $\gamma_{bs} = \gamma_{bs}(p) \in (0, 1)$ is the unique solution of

$$\gamma_{bs} \log \frac{\gamma_{bs}}{p} + (1 - \gamma_{bs}) \log \frac{1 - \gamma_{bs}}{1 - p} - \log 2 = 0. \tag{1.1}$$

For any $\epsilon > 0$, let $\varrho_{bs}(\epsilon, p)$ denote the probability that there exists an infinite ray\(^1\) \{ $e =: x_0, x_1, x_2, \ldots$ \} such that $U_{bs}(x_j) \geq (\gamma_{bs} - \epsilon)j$ for all $j \geq 1$. It is conjectured by Pemantle [19] that there exists a constant $\beta_{bs}(p)$ such that\(^2\)

$$\log \varrho_{bs}(\epsilon, p) \sim -\frac{\beta_{bs}(p)}{\epsilon^{1/2}}, \quad \epsilon \to 0. \tag{1.2}$$

We prove the conjecture, and give the value of $\beta_{bs}(p)$. Let $\psi_{bs}(t) := \log[2(p \epsilon^t + 1 - p)]$, $t > 0$. Let $t^* = t^*(p) > 0$ be the unique solution of $\psi_{bs}(t^*) = t^*\psi'_{bs}(t^*)$. [One can then check that the solution of equation (1.1) is $\gamma_{bs} = \psi_{bs}(t^*)^t$.] Our main result, Theorem 1.2 below, implies that conjecture (1.2) holds, with

$$\beta_{bs}(p) := \frac{\pi}{2^{1/2}} [t^* \psi''_{bs}(t^*)]^{1/2}.$$ 

A particular value of $\beta_{bs}$ is as follows: if $0 < p_0 < \frac{1}{2}$ is such that $16p_0(1 - p_0) = 1$ (i.e., if $\gamma_{bs}(p_0) = \frac{1}{2}$), then

$$\beta_{bs}(p_0) = \frac{\pi}{4} \left( \frac{\gamma'_{bs}(p_0)}{1 - 2p_0} \right)^{1/2} \log \frac{1}{4p_0},$$

---

\(^1\)By an infinite ray, we mean that each $x_j$ is the parent of $x_{j+1}$.

\(^2\)Throughout the paper, by $a(\epsilon) \sim b(\epsilon)$, $\epsilon \to 0$, we mean $\lim_{\epsilon \to 0} \frac{a(\epsilon)}{b(\epsilon)} = 1$. 

2
where $\gamma'_b(p_0)$ denotes the derivative of $p \mapsto \gamma_b(p)$ at $p_0$. This is, informally, in agreement with the following theorem of Aldous ([1], Theorem 6): if $p \in (p_0, \frac{1}{2})$ is such that $\gamma_b(p) = \frac{1}{2} + \varepsilon$, then the probability that there exists an infinite ray $x$ with $U_b(x_i) \geq \frac{1}{2} i, \forall i \geq 1$, is

$$\exp \left( -\pi \frac{\log(1/(4p_0))}{4(1-2p_0)^{1/2}} \frac{1}{(p-p_0)^{1/2}} + O(1) \right), \quad \varepsilon \to 0. \quad \square$$

As a matter of fact, the main result of this paper (Theorem 1.2 below) is valid for more general branching random walks: the tree $T_b$ can be random (Galton–Watson), the random variables assigned on the vertices of the tree are not necessarily Bernoulli, nor necessarily identically distributed, nor necessarily independent if the vertices share a common parent.

Our model is as follows, which is a one-dimensional discrete-time branching random walk. At the beginning, there is a single particle located at position $x = 0$. Its children, who form the first generation, are positioned according to a certain point process. Each of the particles in the first generation gives birth to new particles that are positioned (with respect to their birth places) according to the same point process; they form the second generation. The system goes on according to the same mechanism. We assume that for any $n$, each particle at generation $n$ produces new particles independently of each other and of everything up to the $n$-th generation.

We denote by $(U(x), |x| = n)$ the positions of the particles in the $n$-th generation, and by $Z_n := \sum_{|x|=n} 1$ the number of particles in the $n$-th generation. Clearly, $(Z_n, n \geq 0)$ forms a Galton–Watson process. [In Example 1.1, $Z_n = 2^n$, whereas $(U(x), |x| = 1)$ is a pair of independent Bernoulli($p$) random variables.]

We assume that for some $\delta > 0$,

$$E(Z_1^{1+\delta}) < \infty, \quad E(Z_1) > 1; \quad (1.3)$$

in particular, the Galton–Watson process $(Z_n, n \geq 0)$ is supercritical. We also assume that there exist $\delta_+ > 0$ and $\delta_- > 0$ such that

$$E \left( \sum_{|x|=1} e^{\delta_+ U(x)} \right) < \infty, \quad E \left( \sum_{|x|=1} e^{-\delta_- U(x)} \right) < \infty. \quad (1.4)$$

An additional assumption is needed (which in Example 1.1 corresponds to the condition $p < \frac{1}{2}$). Let us define the logarithmic generating function for the branching walk:

$$\psi(t) := \log E \left( \sum_{|x|=1} e^{tU(x)} \right), \quad t > 0. \quad (1.5)$$
Let \( \zeta := \sup \{ t : \psi(t) < \infty \} \). Under Condition (1.4), we have \( 0 < \zeta \leq \infty \), and \( \psi \) is \( C^\infty \) on \((0, \zeta)\). We assume that there exists \( t^* \in (0, \zeta) \) such that

\[
(1.6) \quad \psi(t^*) = t^* \psi'(t^*).
\]

For discussions on this condition, see the examples presented after Theorem 1.2 below.

Recall that (Kingman [14], Hammersley [8], Biggins [2]) conditioned on the survival of the system,

\[
(1.7) \quad \lim_{n \to \infty} \frac{1}{n} \max_{|x| = n} U(x) = \gamma, \quad \text{a.s.}
\]

where \( \gamma := \frac{\psi(t^*)}{t^*} \) is a constant, with \( t^* \) and \( \psi(\cdot) \) defined in (1.6) and (1.5), respectively.

For \( \varepsilon > 0 \), let \( \varrho_U(\varepsilon) \) denote the probability that there exists an infinite ray \( \{ e =: x_0, x_1, x_2, \ldots \} \) such that \( U(x_j) \geq (\gamma - \varepsilon) j \) for all \( j \geq 1 \). Our main result is as follows.

**Theorem 1.2** Assume (1.3) and (1.4). If (1.6) holds, then

\[
(1.8) \quad \log \varrho_U(\varepsilon) \sim -\frac{\pi}{(2\varepsilon)^{1/2}} [t^* \psi''(t^*)]^{1/2}, \quad \varepsilon \to 0,
\]

where \( t^* \) and \( \psi \) are as in (1.6) and (1.5), respectively.

Since \((U(x), |x| = 1)\) is not a deterministic set (excluded by the combination of (1.6) and (1.3)), the function \( \psi \) is strictly convex on \((0, \zeta)\). In particular, we have \( 0 < \psi''(t^*) < \infty \).

We now present a few simple examples to illustrate the meaning of Assumption (1.6). For more detailed discussions, see Jaffuel [11].

**Example 1.1** (continuation). In Example 1.1, Conditions (1.3) and (1.4) are obviously satisfied, whereas (1.6) is equivalent to \( p < \frac{1}{2} \). In this case, (1.8) becomes (1.2). Clearly, if \( p > \frac{1}{2} \), \( \varrho_{bs}(\varepsilon, p) \) does not go to 0 because the vertices labeled with 1 percolate, with positive probability, on the tree.

**Example 1.3** Consider the example of Bernoulli branching random walk, i.e., such that \( U(x) \in \{0, 1\} \) for any \( |x| = 1 \); to avoid trivial cases, we assume \( \mathbb{E}(\sum_{|x|=1} 1_{\{U(x)=1\}}) > 0 \) and \( \mathbb{E}(\sum_{|x|=1} 1_{\{U(x)=0\}}) > 0 \).

Condition (1.4) is automatically satisfied as long as we assume (1.3). Elementary computations show that Condition (1.6) is equivalent to \( \mathbb{E}(\sum_{|x|=1} 1_{\{U(x)=1\}}) < 1 \). (In particular, if we assign independent Bernoulli(\( p \)) random variables on the vertices of a rooted binary tree, we recover Example 1.1). Again, if \( \mathbb{E}(\sum_{|x|=1} 1_{\{U(x)=1\}}) > 1 \), \( \varrho_U(\varepsilon) \) does not go to 0 because the vertices labeled with 1 percolate, with positive probability, on the tree. \( \Box \)
**Example 1.4** Assume the distribution of $U$ is bounded from above, in the sense that there exists a constant $C \in \mathbb{R}$ such that $\sup_{|x|=1} U(x) \leq C$. Let $s_U := \text{ess sup} \sup_{|x|=1} U(x) = \sup\{a \in \mathbb{R} : P\{\sup_{|x|=1} U(x) \geq a\} > 0\} < \infty$. Under (1.3) and (1.4), Condition (1.6) is satisfied if and only if $E(\sum_{|x|=1} 1_{\{U(x)=s_U\}}) < 1$. □

**Example 1.5** Assume that (1.3) holds true. If $\text{ess sup} \sup_{|x|=1} U(x) = \infty$, then Condition (1.6) is satisfied. □

We mention that the question we address here in the discrete case has a continuous counterpart, which has been investigated in the context of the F-KPP equation with cutoff, see [5], [6], [7].

The rest of the paper is organized as follows. In Section 2, we make a linear transformation of our branching random walk so that it will become a boundary case in the sense of Biggins and Kyprianou [3]; the linear transformation is possible due to Assumption (1.6). Section 3 is devoted to the proof of the upper bound in Theorem 1.2, whereas the proof of the lower bound is in Section 4.

## 2 A linear transformation

We define
\[ V(x) := -t^*U(x) + \psi(t^*) |x|. \]

Then
\[ E\left( \sum_{|x|=1} e^{-V(x)} \right) = 1, \quad E\left( \sum_{|x|=1} V(x)e^{-V(x)} \right) = 0. \]

Since $t^* < \zeta$, there exists $\delta_1 > 0$ such that
\[ E\left( \sum_{|x|=1} e^{-(1+\delta_1)V(x)} \right) < \infty. \]

On the other hand, by (1.4), there exists $\delta_2 > 0$ such that
\[ E\left( \sum_{|x|=1} e^{\delta_2 V(x)} \right) < \infty. \]

The new branching random walk $(V(x))$ satisfies $\lim_{n \to \infty} \frac{1}{n} \inf_{|x|=n} V(x) = 0$ a.s. conditioned on non-extinction. Let
\[ \varrho(\varepsilon) = \varrho(V, \varepsilon) := P\left\{ \exists \text{ infinite ray } \{e =: x_0, x_1, x_2, \ldots\} : V(x_j) \leq \varepsilon j, \forall j \geq 1 \right\}. \]
Theorem 1.2 will be a consequence of the following estimate: assuming (2.2), then
\begin{equation}
\log \rho(\varepsilon) \sim -\frac{\pi \sigma}{(2\varepsilon)^{1/2}}, \quad \varepsilon \to 0,
\end{equation}
where \( \sigma \) is the constant in (2.7) below.

It is (2.6) we are going to prove: an upper bound is proved in Section 3, and a lower bound in Section 4.

We conclude this section with a change-of-probabilities formula, which is the raison d’être of the linear transformation. Let \( S_0 := 0 \), and let \( (S_i - S_{i-1}, i \geq 1) \) be a sequence of i.i.d. random variables such that for any measurable function \( f : \mathbb{R} \to [0, \infty) \),
\[
\mathbb{E}(f(S_1)) = \mathbb{E}\left( \sum_{|x|=1} e^{-V(x)} f(V(x)) \right).
\]
In particular, \( \mathbb{E}(S_1) = 0 \) (by (2.2)). In words, \((S_n)\) is a mean-zero random walk. We denote
\begin{equation}
\sigma^2 := \mathbb{E}(S_1^2) = \mathbb{E}\left( \sum_{|x|=1} V(x)^2 e^{-V(x)} \right) = (t^*)^2 \psi''(t^*).
\end{equation}

Since \( \mathbb{E}(Z_1^{1+\delta}) < \infty \) (Condition (1.3)) and \( \mathbb{E}\left( \sum_{|x|=1} e^{-(1+\delta)V(x)} \right) < \infty \) (see (2.3)), there exists \( \delta_3 > 0 \) such that \( \mathbb{E}(e^{uS_1}) < \infty \) for all \( |u| \leq \delta_3 \).

In view of (2.2), we have, according to Biggins and Kyprianou [3], for any \( n \geq 1 \) and any measurable function \( F : \mathbb{R}^n \to [0, \infty) \),
\begin{equation}
\mathbb{E}\left( \sum_{|x|=n} e^{-V(x)} F(V(x), 1 \leq i \leq n) \right) = \mathbb{E}[F(S_i, 1 \leq i \leq n)],
\end{equation}
where, for any \( x \) with \( |x| = n \), \( \{e =: x_0, x_1, \ldots, x_n := x\} \) is the shortest path connecting \( e \) to \( x \).

We now give a bivariate version of (2.8). For any vertex \( x \), the number of its children is denoted by \( \nu(x) \). Condition (1.3) guarantees that \( \mathbb{P}\{\nu(x) < \infty, \forall x\} = 1 \). In light of (2.2), we have, for any \( n \geq 1 \) and any measurable function \( F : \mathbb{R}^n \times \mathbb{R}^n \to [0, \infty) \),
\begin{equation}
\mathbb{E}\left( \sum_{|x|=n} e^{-V(x)} F[V(x_i), \nu(x_{i-1}), 1 \leq i \leq n] \right) = \mathbb{E}\left( F[S_i, \nu_{i-1}, 1 \leq i \leq n] \right),
\end{equation}
where \((S_i - S_{i-1}, \nu_{i-1})\), for \( i \geq 1 \), are i.i.d. random vectors, whose common distribution is determined by (recalling that \( Z_1 := \#\{y : |y| = 1\} \))
\begin{equation}
\mathbb{E}[f(S_1, \nu_0)] = \mathbb{E}\left( \sum_{|x|=1} e^{-V(x)} f(V(x), Z_1) \right),
\end{equation}
6
for any measurable function \( f : \mathbb{R}^2 \rightarrow [0, \infty) \).

The proof of (2.9), just as the proof of (2.8) in Biggins and Kyprianou [3], relies on a simple argument by induction on \( n \). We feel free to omit it.

[We mention that (2.9) is a special case of the so-called spinal decomposition for branching random walks, a powerful tool developed by Lyons, Pemantle and Peres [16] and Lyons [15]. The idea of spinal decomposition, which goes back at least to Kahane and Peyrière [12], has been used in the literature by many authors in several different forms.]

We now extend a useful result of Mogulskii [18] to arrays of random variables.

Lemma 2.1 (A triangular version of Mogulskii [18]) For each \( n \geq 1 \), let \( X_1^{(n)} \), \( 1 \leq i \leq n \), be i.i.d. real-valued random variables. Let \( g_1 < g_2 \) be continuous functions on \([0, 1]\) with \( g_1(0) < 0 < g_2(0) \). Let \( (a_n) \) be a sequence of positive numbers such that \( a_n \rightarrow \infty \) and that \( \frac{a_n^2}{n} \rightarrow 0 \). Assume that there exist constants \( \eta > 0 \) and \( \sigma^2 > 0 \) such that

\[
\sup_{n \geq 1} \mathbb{E}(|X_1^{(n)}|^{2+\eta}) < \infty, \quad \mathbb{E}(X_1^{(n)}) = o\left(\frac{a_n}{n}\right), \quad \text{Var}(X_1^{(n)}) \rightarrow \sigma^2.
\]

Consider the measurable event

\[
E_n := \left\{ g_1\left(\frac{i}{n}\right) \leq \frac{S_i^{(n)}}{a_n} \leq g_2\left(\frac{i}{n}\right), \text{ for } 1 \leq i \leq n \right\},
\]

where \( S_i^{(n)} := X_1^{(n)} + \cdots + X_i^{(n)} \). We have

\[
\lim_{n \rightarrow \infty} \frac{a_n^2}{n} \log \mathbb{P}\{E_n\} = -\frac{\pi^2 \sigma^2}{2} \int_0^1 \frac{dt}{[g_2(t) - g_1(t)]^2}.
\]

Moreover, for any \( b > 0 \),

\[
\lim_{n \rightarrow \infty} \frac{a_n^2}{n} \log \mathbb{P}\left\{ E_n, \frac{S_i^{(n)}}{a_n} \geq g_2(1) - b \right\} = -\frac{\pi^2 \sigma^2}{2} \int_0^1 \frac{dt}{[g_2(t) - g_1(t)]^2}.
\]

If the distribution of \( X_1^{(n)} \) does not depend on \( n \), Lemma 2.1 is Mogulskii [18]’s result. In this case, condition (2.11) is satisfied as long as \( X_1^{(n)} \) is centered, having a finite \((2 + \eta)\)-moment (for some \( \eta > 0 \)), and such that it is not identically zero.\(^3\)

The proof of Lemma 2.1 is in the same spirit (but with some additional technical difficulties) as in the original work of Mogulskii [18], and is included as an appendix at the end of the paper. We mention that as in [18], it is possible to have a version of Lemma 2.1 when \( X_1^{(n)} \) belongs to the domain of attraction of a stable non-Gaussian law, except that the constant \( \frac{\pi^2}{2} \) in (2.12)–(2.13) will be implicit.

\(^3\)In this case, we even can allow \( \eta = 0 \); see [18].
3 Proof of Theorem 1.2: the upper bound

In this section, we prove the upper bound in (2.6):

\[
\limsup_{\varepsilon \to 0} \varepsilon^{1/2} \log \varrho(\varepsilon) \leq -\frac{\pi \sigma}{2^{1/2}},
\]

where \(\varrho(\varepsilon)\) is defined in (2.5), and \(\sigma\) is the constant in (2.7).

The main idea in this section is borrowed from Kesten [13]. We start with the trivial inequality that for any \(n \geq 1\) (an appropriate value for \(n = n(\varepsilon)\) will be chosen later on),

\[
\varrho(\varepsilon) \leq \mathbb{P}\{\exists x : |x| = n, V(x_i) \leq \varepsilon i, \forall i \leq n\}.
\]

Let \((b_i, i \geq 0)\) be a sequence of non-negative real numbers whose value (depending on \(n\)) will be given later on. For any \(x\), let \(H(x) := \inf\{i : 1 \leq i \leq |x|, V(x_i) \leq \varepsilon i - b_i\}\), with \(\inf \emptyset := \infty\). Then \(\mathbb{P}\{H(x) = \infty\} + \mathbb{P}\{H(x) \leq |x|\} = 1\). Therefore,

\[
\varrho(\varepsilon) \leq \varrho_1(\varepsilon) + \varrho_2(\varepsilon),
\]

where

\[
\varrho_1(\varepsilon) = \varrho_1(\varepsilon, n) := \mathbb{P}\{\exists |x| = n : H(x) = \infty, V(x_i) \leq \varepsilon i, \forall i \leq n\},
\]

\[
\varrho_2(\varepsilon) = \varrho_2(\varepsilon, n) := \mathbb{P}\{\exists |x| = n : H(x) \leq n, V(x_i) \leq \varepsilon i, \forall i \leq n\}.
\]

We now estimate \(\varrho_1(\varepsilon)\) and \(\varrho_2(\varepsilon)\) separately.

By definition,

\[
\varrho_1(\varepsilon) = \mathbb{P}\{\exists |x| = n : \varepsilon i - b_i < V(x_i) \leq \varepsilon i, \forall i \leq n\}
\]

\[= \mathbb{P}\left\{ \sum_{|x|=n} 1_{\{\varepsilon i - b_i < V(x_i) \leq \varepsilon i, \forall i \leq n\}} \geq 1 \right\}
\]

\[\leq \mathbb{E}\left( \sum_{|x|=n} 1_{\{\varepsilon i - b_i < V(x_i) \leq \varepsilon i, \forall i \leq n\}} \right),
\]

the last inequality being a consequence of Chebyshev’s inequality. Applying the change-of-probabilities formula (2.8) to \(F(z) := e^{\varepsilon n} 1_{\{\varepsilon i - b_i < z_i \leq \varepsilon i, \forall i \leq n\}}\) for \(z := (z_1, \ldots, z_n) \in \mathbb{R}^n\), this yields, in the notation of (2.8),

\[
(3.2) \quad \varrho_1(\varepsilon) \leq \mathbb{E}\left(e^{\varepsilon n} 1_{\{\varepsilon i - b_i < S_i \leq \varepsilon i, \forall i \leq n\}}\right) \leq e^{\varepsilon n} \mathbb{P}\{\varepsilon i - b_i < S_i \leq \varepsilon i, \forall i \leq n\}.
\]
To estimate $\varrho_2(\varepsilon)$, we observe that

$$
\varrho_2(\varepsilon) \leq \sum_{j=1}^{n} P\left\{ \exists |x| = n : H(x) = j, V(x_i) \leq \varepsilon_i, \forall i \leq n \right\}
$$

$$
\leq \sum_{j=1}^{n} P\left\{ \exists |x| = n : H(x) = j, V(x_i) \leq \varepsilon_i, \forall i \leq j \right\}.
$$

Since $\{\exists |x| = n : H(x) = j, V(x_i) \leq \varepsilon_i, \forall i \leq j\} \subset \{\exists |y| = j : H(y) = j, V(y_i) \leq \varepsilon_i, \forall i \leq j\}$, this yields

$$
\varrho_2(\varepsilon) \leq \sum_{j=1}^{n} P\left\{ \exists |y| = j : \varepsilon_i - b_i < V(y_i) \leq \varepsilon_i, \forall i < j, V(y_j) \leq \varepsilon_j - b_j \right\}.
$$

We can now use the same argument as for $\varrho_1(\varepsilon)$, namely, Chebyshev’s inequality and then the change-of-probability formula (2.2), to see that

$$
\varrho_2(\varepsilon) \leq \sum_{j=1}^{n} E\left( \sum_{|y| = j}^{n} \mathbf{1}_{\{\varepsilon_i - b_i < V(y_i) \leq \varepsilon_i, \forall i < j, V(y_j) \leq \varepsilon_j - b_j\}} \right)
$$

$$
= \sum_{j=1}^{n} E\left( e^{S_j} \mathbf{1}_{\{\varepsilon_i - b_i < S_i \leq \varepsilon_i, \forall i < j, S_j \leq \varepsilon_j - b_j\}} \right)
$$

$$
\leq \sum_{j=1}^{n} e^{\varepsilon_j - b_j} P\left\{ \varepsilon_i - b_i < S_i \leq \varepsilon_i, \forall i < j \right\}.
$$

Together with (3.2), and recalling that $\varrho(\varepsilon) \leq \varrho_1(\varepsilon) + \varrho_2(\varepsilon)$, this yields

$$
\varrho(\varepsilon) \leq e^n P\left\{ \varepsilon_i - b_i < S_i \leq \varepsilon_i, \forall i \leq n \right\} + \sum_{j=1}^{n} e^{\varepsilon_j - b_j} P\left\{ \varepsilon_i - b_i < S_i \leq \varepsilon_i, \forall i < j \right\}
$$

$$
= e^n I(n) + \sum_{j=0}^{n-1} e^{\varepsilon(j+1) - b_{j+1}} I(j),
$$

where $I(0) := 1$ and

$$
I(j) := P\left\{ \varepsilon_i - b_i < S_i \leq \varepsilon_i, \forall i \leq j \right\}, \quad 1 \leq j \leq n.
$$

The idea is now to apply Mogulskii’s estimate (2.12) to $I(j)$ for suitably chosen $(b_i)$. Unfortunately, since $\varepsilon$ depends on $n$, we are not allowed to apply (2.12) simultaneously to all $I(j), 0 \leq j \leq n$. So let us first work a little bit more, and then apply (2.12) to only a few of the $I(j)$.
We assume that \((b_i)\) is non-increasing. Fix an integer \(N \geq 2\), and take \(n := kN\) for \(k \geq 1\). Then
\[
\varrho(\varepsilon) \leq e^{\varepsilon kN}I(kN) + \sum_{j=0}^{k-1} e^{\varepsilon(j+1)-b_{j+1}}I(j) + \sum_{\ell=1}^{N-1} \sum_{j=\ell k}^{(\ell+1)k-1} e^{\varepsilon(j+1)-b_{j+1}}I(j)
\]
(3.3) \[
\leq e^{\varepsilon kN}I(kN) + k \exp(\varepsilon k - b_k) + k \sum_{\ell=1}^{N-1} \exp(\varepsilon(\ell + 1)k - b(\ell+1)k)I(\ell k).
\]

We choose \(b_i = b_i(n) := b(n - i)^{1/3} = b(kN - i)^{1/3}, 0 \leq i \leq n\), and \(\varepsilon := \frac{\theta}{\alpha^{2/3}} = \frac{\theta}{(Nk)^{2/3}}\), where \(b > 0\) and \(\theta > 0\) are constants. By definition, for \(1 \leq \ell \leq N\),
\[
I(\ell k) = \mathbb{P}\left\{ \theta \left( \frac{\ell}{N} \right)^{2/3} \frac{i}{\ell k} - b \left( \frac{N}{\ell} - \frac{i}{\ell k} \right)^{1/3} < \frac{S_i}{(\ell k)^{1/3}} \leq \theta \left( \frac{\ell}{N} \right)^{2/3} \frac{i}{\ell k}, \forall i \leq \ell k \right\}.
\]
Applying (2.12) to \(g_1(t) := \theta(\frac{t}{N})^{2/3} - b(\frac{N}{t} - t)^{1/3}\) and \(g_2(t) := \theta(\frac{t}{N})^{2/3}t\), we see that, for \(1 \leq \ell \leq N\),
\[
\limsup_{k \to \infty} \frac{1}{(\ell k)^{1/3}} \log I(\ell k) \leq -\frac{\pi^2 \sigma^2}{2b^2} \int_0^1 \frac{dt}{(\frac{N}{t} - t)^{2/3}} = -\frac{3\pi^2 \sigma^2}{2b^2} \frac{N^{1/3} - (N - \ell)^{1/3}}{\ell^{1/3}},
\]
where \(\sigma\) is the constant in (2.7). Going back to (3.3), we obtain:
\[
\limsup_{k \to \infty} \frac{\theta^{1/2}}{(Nk)^{1/3}} \log \frac{\theta}{(Nk)^{2/3}} \leq \theta^{1/2} \alpha_{N,b},
\]
where the constant \(\alpha_{N,b} = \alpha_{N,b}(\theta)\) is defined by
\[
\alpha_{N,b} := \max_{1 \leq \ell \leq N-1} \left\{ \frac{3\pi^2 \sigma^2}{2b^2}, \frac{\theta}{N} - b(1 - \frac{1}{N})^{1/3}, \frac{\theta(\ell + 1)}{N} - b(1 - \frac{\ell + 1}{N})^{1/3} - \frac{3\pi^2 \sigma^2}{2b^2} \frac{N^{1/3} - (N - \ell)^{1/3}}{\ell^{1/3}} \right\}.
\]
Since \(\varepsilon \mapsto \varrho(\varepsilon)\) is non-increasing, this yields
\[
\limsup_{\varepsilon \to 0} \varepsilon^{1/2} \log \varrho(\varepsilon) \leq \theta^{1/2} \alpha_{N,b}.
\]
We let \(N \to \infty\). By definition,
\[
\limsup_{N \to \infty} \alpha_{N,b} \leq \max \left\{ \theta - \frac{3\pi^2 \sigma^2}{2b^2}, -b, f(\theta, b) \right\},
\]
where \(f(\theta, b) := \sup_{t \in [0,1]} \{ \theta t - b(1 - t)^{1/3} - \frac{3\pi^2 \sigma^2}{2b^2} [1 - (1 - t)^{1/3}] \} \).
Elementary computations show that as long as $b < \frac{3\pi^2\sigma^2}{2b^2} \leq b + 3\theta$, we have $f(\theta, b) = \theta - \frac{3\pi^2\sigma^2}{2b^2} + \frac{2}{3(3\theta)^{3/2}}(\frac{3\pi^2\sigma^2}{2b^2} - b)^{3/2}$. Thus $\max\{\theta - \frac{3\pi^2\sigma^2}{2b^2}, -b, f(\theta, b)\} = \max\{f(\theta, b), -b\}$, which equals $-b$ if $\theta = \frac{\pi^2\sigma^2}{2b^2} - \frac{b}{3}$. As a consequence, for any $b > 0$ satisfying $b < \frac{3\pi^2\sigma^2}{2b^2}$,

$$\limsup_{\varepsilon \to 0} \varepsilon^{1/2} \log \varepsilon \leq -b \sqrt{\frac{\pi^2\sigma^2}{2b^2} - \frac{b^3}{3}}.$$ 

Letting $b \to 0$, this yields (3.1) and completes the proof of the upper bound in Theorem 1.2. □

4 Proof of Theorem 1.2: the lower bound

Before proceeding to the proof of the lower bound in Theorem 1.2, we recall two inequalities: the first gives a useful lower tail estimate for the number of individuals in a super-critical Galton–Watson process conditioned on survival, whereas the second concerns an elementary property of the conditional distribution of a sum of independent random variables. Let us recall that $Z_n$ is the number of particles in the $n$-th generation.

**Fact 4.1** (McDiarmid [17]) There exists $\vartheta > 1$ such that

$$(4.1) \quad \mathbb{P}\{Z_n \leq \vartheta^n | Z_n > 0\} \leq \vartheta^{-n}, \quad \forall n \geq 1.$$ 

**Fact 4.2** ([9]) If $X_1, X_2, \ldots, X_N$ are independent non-negative random variables, and if $F : (0, \infty) \to \mathbb{R}_+$ is non-increasing, then

$$\mathbb{E}\left[F\left(\sum_{i=1}^N X_i\right) \mid \sum_{i=1}^N X_i > 0\right] \leq \max_{1 \leq i \leq N} \mathbb{E}[F(X_i) \mid X_i > 0].$$ 

This section is devoted to the proof of the lower bound in (2.6):

$$(4.2) \quad \liminf_{\varepsilon \to 0} \varepsilon^{1/2} \log \varepsilon \geq -\frac{\pi \sigma}{2^{1/2}},$$ 

where $\varepsilon$ and $\sigma$ are as in (2.5) and (2.7), respectively.

The basic idea consists in constructing a new Galton–Watson tree $G = G(\varepsilon)$ within the branching random walk, and obtaining a lower bound for $\varepsilon$ in terms of $G$.

Recall from (1.7) that conditioned on survival, $\frac{1}{j} \max_{|z|\leq j} V(z)$ converges almost surely, for $j \to \infty$, to a finite constant. [The fact that this limiting constant is finite is a consequence of...
\(E(\sum_{|x|=1} e^{\delta_x V(x)}) < \infty \) in (2.4). Since the system survives with (strictly) positive probability, we can fix a sufficiently large constant \(M > 0\) such that

\[(4.3) \inf_{j \geq 0} \mathbb{P}\left\{ \max_{|x| \leq j} V(x) \leq Mj \right\} \geq \frac{1}{2}, \quad \kappa := \inf_{j \geq 0} \mathbb{P}\left\{ Z_j > 0, \ \max_{|x| \leq j} V(x) \leq Mj \right\} > 0,
\]

where, as before, \(Z_j := \#\{x : |x| = j\}\).

Fix a constant \(0 < \alpha < 1\). For any integers \(n > L \geq 1\) with \((1 - \alpha)\varepsilon L \geq M(n - L)\), we consider the set \(G_{n,\varepsilon} = G_{n,\varepsilon}(L)\) defined by

\[G_{n,\varepsilon} := \{|x| = n : V(x_i) \leq \alpha \varepsilon i, \text{ for } 1 \leq i \leq L; \ \max_{z > x_L : |z| \leq n} [V(z) - V(x_L)] \leq (1 - \alpha)\varepsilon L\}.
\]

By definition, for any \(x \in G_{n,\varepsilon}\), we have \(V(x_i) \leq \varepsilon i\), for \(1 \leq i \leq n\).

If \(G_{n,\varepsilon} \neq \emptyset\), the elements of \(G_{n,\varepsilon}\) form the first generation of the new Galton–Watson tree \(G_{n,\varepsilon}\), and we construct \(G_{n,\varepsilon}\) by iterating the same procedure: for example, the second generation in \(G_{n,\varepsilon}\) consists of \(y\) with \(|y| = 2n\) being a descendant of some \(x \in G_{n,\varepsilon}\) such that \(V(y_{n+1}) - V(x) \leq \alpha \varepsilon i\), for \(1 \leq i \leq L\) and \(\max_{z > y_{n+L} : |z| \leq 2n}[V(z) - V(y_{n+L})] \leq (1 - \alpha)\varepsilon L\).

Let \(q_{n,\varepsilon}\) denote the probability of extinction of the Galton–Watson tree \(G_{n,\varepsilon}\). It is clear that

\[\varrho(\varepsilon) \geq 1 - q_{n,\varepsilon},\]

so we only need to find a lower bound for \(1 - q_{n,\varepsilon}\). In order to do so, we introduce, for \(b \in \mathbb{R}\) and \(n \geq 1\),

\[(4.4) \varrho(b, n) := \mathbb{P}\left\{ \exists |x| = n : V(x_i) \leq b i, \text{ for } 1 \leq i \leq n \right\}.
\]

Let us first prove some preliminary results.

**Lemma 4.3** Let \(0 < \alpha < 1\) and \(\varepsilon > 0\). Let \(n > L \geq 1\) be such that \((1 - \alpha)\varepsilon L \geq M(n - L)\). Then

\[\mathbb{P}\{G_{n,\varepsilon} \neq \emptyset\} \geq \frac{1}{2} \varrho(\alpha \varepsilon, n).
\]

**Proof.** By definition,

\[\mathbb{P}\{G_{n,\varepsilon} \neq \emptyset\} = E(\mathbf{1}_{|y| = L : V(y_i) \leq \alpha \varepsilon i, \forall i \leq L}) \mathbb{P}\left\{ \max_{|z| \leq n-L} V(z) \leq (1 - \alpha)\varepsilon L \right\}.
\]

Since \((1 - \alpha)\varepsilon L \geq M(n - L)\), it follows from (4.3) that

\[\mathbb{P}\{G_{n,\varepsilon} \neq \emptyset\} \geq \frac{1}{2} \mathbb{P}\{ \exists |y| = L : V(y_i) \leq \alpha \varepsilon i, \forall i \leq L\},
\]

and the r.h.s. is at least \(\frac{1}{2} \varrho(\alpha \varepsilon, n)\). \(\square\)

\(^{\text{4}}\)We write \(z > x\) if \(x\) is an ancestor of \(z\).
Lemma 4.4 Let $0 < \alpha < 1$ and $\varepsilon > 0$. Let $n > L \geq 1$ be such that $(1 - \alpha)\varepsilon L \geq M(n - L)$. We have

\[ P\{1 \leq \#G_{n,\varepsilon} \leq \vartheta^{n-L}\} \leq \frac{1}{\kappa \vartheta^{n-L}}, \tag{4.5} \]

where $\kappa > 0$ and $\vartheta > 1$ are the constants in (4.3) and (4.1), respectively.

Proof. By definition,

\[ \#G_{n,\varepsilon} = \sum_{|x| = L} \eta_x 1\{V(x_i) \leq \alpha \varepsilon, \forall i \leq L\}, \]

where

\[ \eta_x := \#\{y > x : |y| = n\} 1_{\{\max\{z > x : |z| \leq n\}|V(z) - V(x)| \leq (1 - \alpha)\varepsilon L\}. \]

By Fact 4.2, for any $\ell \geq 1$, with $F(x) = 1_{\{x \leq \ell\}},$

\[ P\{\#G_{n,\varepsilon} \leq \ell \mid \#G_{n,\varepsilon} > 0\} \leq P\{Z_{n-L} \leq \ell \mid Z_{n-L} > 0, \max_{|z| \leq n-L} V(z) \leq (1 - \alpha)\varepsilon L\}, \]

where, as before, $Z_{n-L} := \#\{|x| = n - L\}$. Since $(1 - \alpha)\varepsilon L \geq M(n - L)$, it follows from (4.3) that $P\{Z_{n-L} > 0, \max_{|z| \leq n-L} V(z) \leq (1 - \alpha)\varepsilon L\} \geq \kappa > 0$. Therefore,

\[ P\{1 \leq \#G_{n,\varepsilon} \leq \ell\} \leq \frac{1}{\kappa} P\{Z_{n-L} \leq \ell \mid Z_{n-L} > 0\}. \]

This implies (4.5) by means of Fact 4.1. \qed

To state the next estimate, we recall that $\nu(x)$ is the number of children of $x$, and that $(S_i - S_{i-1}, \nu_{i-1}), i \geq 1$, are i.i.d. random vectors (with $S_0 := 0$) whose common distribution is given by (2.10).

Lemma 4.5 Let $n \geq 1$. For any $1 \leq i \leq n$, let $I_{i,n} \subset \mathbb{R}$ be a Borel set. Let $r_n \geq 1$ be an integer. We have

\[ P\{\exists |x| = n : V(x_i) \in I_{i,n}, \forall 1 \leq i \leq n\} \geq \frac{E[e^{S_{n-1}} 1_{\{S_{i-1} \leq r_n, \forall 1 \leq i \leq n\}}]}{1 + (r_n - 1) \sum_{j=1}^{n} h_{j,n}}, \]

where

\[ h_{j,n} := \sup_{u \in I_{j,n}} E(e^{S_{n-j}} 1_{\{S_{\ell} \in I_{\ell+j,n-u}, \forall 0 \leq \ell \leq n-j\}}), \tag{4.6} \]

and $I_{\ell+j,n-u} := \{v - u : v \in I_{\ell+j,n}\}$.
Proof. Let

$$Y_n := \sum_{|x|=n} \mathbf{1}_{\{V(x) \in I_n, \nu(x_{i-1}) \leq r_n, \forall 1 \leq i \leq n\}}.$$  

By definition,

$$E(Y_n^2) = E\left( \sum_{|x|=n} \sum_{|y|=n} \mathbf{1}_{\{V(x) \in I_n, \nu(x_{i-1}) \leq r_n, V(y) \in I_n, \nu(y_{i-1}) \leq r_n, \forall 1 \leq i \leq n\}} \right)$$

(4.7)  

$$= E(Y_n) + E\left( \sum_{j=0}^{n-1} \sum_{|z|=j} \mathbf{1}_{\{V(z) \in I_n, \nu(z_{i-1}) \leq r_n, \forall i \leq j\}} D_{j+1,n}(z) \right),$$

with

$$D_{j+1,n}(z) := \sum_{(x_{j+1},y_{j+1})} \sum_{(x,y)} \mathbf{1}_{\{V(x) \in I_n, \nu(x_{i-1}) \leq r_n, \forall j+1 \leq i \leq n\}},$$

where the double sum $\sum_{(x_{j+1},y_{j+1})}$ is over pairs $(x_{j+1}, y_{j+1})$ of distinct children of $z$ (thus $|x_{j+1}| = |y_{j+1}| = j + 1$), while $\sum_{(x,y)}$ is over pairs $(x, y)$ with $|x| = |y| = n$ such that $x \geq x_{j+1}$ and $y \geq y_{j+1}$.

The $E[\sum_{j=0}^{n-1} \sum_{|z|=j} \mathbf{1}_{\{\cdots\}} D_{j+1,n}(z)]$ expression on the right-hand side of (4.7) is bounded by

$$E\left( \sum_{j=0}^{n-1} \sum_{|z|=j} \mathbf{1}_{\{V(z) \in I_n, \nu(z_{i-1}) \leq r_n, \forall i \leq j\}} \sum_{(x_{j+1},y_{j+1})} \sum_{x} \mathbf{1}_{\{V(x) \in I_n, \nu(x_{i-1}) \leq r_n, \forall j+1 \leq i \leq n\}} \ h_{j+1,n}\right),$$

where $h_{j+1,n} := \sup_{u \in I_{j+1,n}} E[\sum_{|y|=n-j-1} \mathbf{1}_{\{V(y) \in I_{j+1,n} - u, \forall 0 \leq \ell \leq n-j-1\}}]$, which is in agreement with (4.6), thanks to the change of probability formula (2.8). [The sum $\sum_x$ is, of course, still over $x$ with $|x| = n$ such that $x \geq x_{j+1}$.]

Thanks to the condition $\nu(x_j) \leq r_n$ (i.e., $\nu(z) \leq r_n$), we see that the sum $\sum_{y_{j+1}}$ in the last display gives at most a factor of $r_n - 1$; which yields that the last display is at most $(r_n - 1) E(\sum_{j=0}^{n-1} Y_n h_{j+1,n})$. In other words, we have proved that

$$E\left( \sum_{j=0}^{n-1} \sum_{|z|=j} \mathbf{1}_{\{V(z) \in I_n, \nu(z_{i-1}) \leq r_n, \forall i \leq j\}} D_{j+1,n}(z) \right) \leq (r_n - 1) \sum_{j=0}^{n-1} E(Y_n) h_{j+1,n}.$$  

---

5 We write $y \geq x$ if either $y > x$ or $y = x$. 

14
This yields $E(Y_n^2) \leq [1 + (r_n - 1) \sum_{j=0}^{n-1} h_{j+1,n}]E(Y_n)$. Therefore,

$$
(4.8) \quad \frac{E(Y_n^2)}{[E(Y_n)]^2} \leq \frac{1 + (r_n - 1) \sum_{j=1}^{n} h_{j,n}}{E(Y_n)} = \frac{1 + (r_n - 1) \sum_{j=1}^{n} h_{j,n}}{E(e^{S_n 1\{S_i \in I_{i,n}, \nu_{i-1} \leq r_n, \forall 1 \leq i \leq n\})},
$$

the last inequality being a consequence of (2.9). By the Cauchy–Schwarz inequality, $P\{Y_n \geq 1\} \geq \frac{[E(Y_n)]^2}{E(Y_n^2)}$. Recalling the definition of $Y_n$, we obtain from (4.8) that

$$
(4.9) \quad P\{\exists x = n : V(x_i) \in I_{i,n}, \nu(x_{i-1}) \leq r_n, \forall 1 \leq i \leq n\} \geq \frac{E(e^{S_n 1\{S_i \in I_{i,n}, \nu_{i-1} \leq r_n, \forall 1 \leq i \leq n\})]}{1 + (r_n - 1) \sum_{j=1}^{n} h_{j,n}}.
$$

Lemma 4.5 follows immediately from (4.9). \(\square\)

The key step in the proof of the lower bound in Theorem 1.2 is the following estimate.

**Lemma 4.6** For any $\theta > 0$,

$$
\liminf_{n \to \infty} \frac{\log \varrho(\theta n^{-2/3}, n)}{n^{1/3}} \geq -\frac{\pi \sigma}{(2\theta)^{1/2}},
$$

where $\sigma > 0$ is the constant in (2.7).

**Proof.** Let $0 < \lambda < \frac{\pi \sigma}{(2\theta)^{1/2}}$, and let $I_{i,n} := [\frac{\theta_i n^{1/3}}{n^{1/3}} - \lambda n^{1/3}, \frac{\theta_i n^{1/3}}{n^{1/3}}]$ (for $1 \leq i \leq n$). Since $\varrho(\theta n^{-2/3}, n) \geq P\{\exists x = n : V(x_i) \in I_{i,n}, \forall 1 \leq i \leq n\}$, it follows from Lemma 4.5 that for any integer $r_n \geq 1$,

$$
\varrho(\theta n^{-2/3}, n) \geq \frac{E(e^{S_n 1\{S_i \in I_{i,n}, \nu_{i-1} \leq r_n, \forall 1 \leq i \leq n\}}]}{1 + (r_n - 1) \sum_{j=1}^{n} h_{j,n}},
$$

where $h_{j,n}$ is defined in (4.6), while $(S_i - S_{i-1}, \nu_{i-1}), i \geq 1$, are i.i.d. random vectors (with $S_0 := 0$) whose common distribution is given by (2.10).

For any $\theta_1 < \theta$, we have

$$
\Lambda_n \geq e^{\theta_1 n^{1/3}} P\{S_i \in I_{i,n}, \nu_{i-1} \leq r_n, \forall 1 \leq i \leq n, S_n \geq \theta_1 n^{1/3}\}
= e^{\theta_1 n^{1/3}} P\{\theta n^{-1/3} - \lambda \leq S_i \frac{n^{1/3}}{n^{1/3}} \leq \theta n^{-1/3}, \nu_{i-1} \leq r_n, \forall 1 \leq i \leq n, \frac{S_n}{n^{1/3}} \geq \theta_1\}.
$$

For any $n \geq 1$, we consider i.i.d. random variables $X_i^{(n)}, 1 \leq i \leq n$, having the same distribution as $S_1$ conditioned on $\nu_0 \leq r_n$. Let $S_0^{(n)} = 0$ and $S_i := X_1^{(n)} + \cdots + X_i^{(n)}$ for $1 \leq i \leq n$. Then

$$
\Lambda_n \geq e^{\theta_1 n^{1/3}} [P\{\nu_0 \leq r_n\}]^n P\{\theta n^{-1/3} - \lambda \leq S_i^{(n)} \frac{n^{1/3}}{n^{1/3}} \leq \theta n^{-1/3}, \forall 1 \leq i \leq n, \frac{S_n^{(n)}}{n^{1/3}} \geq \theta_1\}.
$$
We now choose \( r_n := [en^{1/4}] \). By definition, \( \mathbb{P}\{\nu_0 > r_n\} = \mathbb{E}(\sum_{|x|=1} e^{-V(x)} 1_{\{Z_1 > r_n\}}) \), where \( Z_1 = \sum_{|y|=1} \) as before. By Markov’s inequality, \( \mathbb{P}\{Z_1 > r_n\} \leq \frac{\mathbb{E}(Z_1^{1+\delta})}{r_n^{1+\delta}} \). Since \( \mathbb{E}(Z_1^{1+\delta}) < \infty \) (Condition (1.3)) and \( \mathbb{E}(\sum_{|x|=1} e^{-(1+\delta)V(x)}) < \infty \) (see (2.3)), an application of Hölder’s inequality confirms that \( \mathbb{P}\{\nu_0 > r_n\} \leq r_n^{-\delta_4} \) for some \( \delta_4 > 0 \) and all sufficiently large \( n \). In view of our choice of \( r_n \), we see that \( [\mathbb{P}\{\nu_0 \leq r_n\}]^n \to 1 \). Therefore, for all sufficiently large \( n \),

\[
\Lambda_n \geq \frac{1}{2} e^{\theta_n n^{1/3}} \mathbb{P}\left\{ \frac{\theta i}{n} - \lambda \leq \frac{S_i(n)}{n^{1/3}} \leq \frac{\theta i}{n}, \forall 1 \leq i \leq n, \frac{S(n)}{n^{1/3}} \geq \theta_1 \right\}.
\]

To deal with the probability expression on the right-hand side, we intend to apply (2.13); so we need to check condition (2.11). Recall that \( S_1 \) has finite exponential moments in the neighbourhood of 0. Thus, the first condition in (2.11), namely, \( \sup_{n \geq 1} \mathbb{E}(|X_1(n)|^{2+\eta}) < \infty \) for some \( \eta > 0 \), is trivially satisfied. To check the second condition, we see that since \( \mathbb{E}(S_1) = 0 \), we have \( \mathbb{E}(X_1(n)) = E|\mathbb{E}[S_1 1_{\{\nu_0 > r_n\}}]|. \) Since \( \mathbb{P}\{\nu_0 > r_n\} \leq r_n^{-\delta_4} \) for some \( \delta_4 > 0 \) and all sufficiently large \( n \), and since \( S_1 \) has some finite exponential moments, the second condition in (2.11), \( \mathbb{E}(X_1(n)) = o(\alpha n) \), is also satisfied (regardless of the value of the sequence \( \alpha_n \to \infty \)) in view of the Cauchy–Schwarz inequality. Moreover, \( \mathbb{E}(X_1(n)) \to 0 \), which yields \( \text{Var}(X_1(n)) \to \mathbb{E}(S_1^2) = 0 = \sigma^2 \): the third and last condition in (2.11) is verified.

We are therefore entitled to apply (2.13): taking \( g_1(t) := \theta t - \lambda \) and \( g_2(t) := \theta t \), we see that for any \( \lambda_1 \in (0, \lambda) \) and all sufficiently large \( n \),

\[
\Lambda_n \geq \frac{1}{2} e^{\theta_n n^{1/3}} \exp\left( -\frac{\pi^2 \sigma^2}{2 \lambda_1^2} n^{1/3} \right),
\]

which implies, for all sufficiently large \( n \),

\[
\rho(\theta n^{-2/3}, n) \geq \frac{1}{2} \frac{\exp[(\theta_1 - \frac{\pi^2 \sigma^2}{2 \lambda_1^2}) n^{1/3}]}{1 + (r_n - 1) \sum_{j=1}^n h_{j,n}}.
\]

To estimate \( \sum_{j=1}^n h_{j,n} \), we observe that

\[
h_{j,n} = \sup_{u \in I_{j,n}} \mathbb{E}\left(e^{S_{n-j}} 1_{\{S_i \in [\frac{\theta_i}{n} - \lambda n^{1/3} - u, \frac{\theta_i}{n} + \lambda n^{1/3} + u], \forall 0 \leq i \leq n-j\}}\right)
\]

\[
= \sup_{u \in [0, \lambda n^{1/3}]} \mathbb{E}\left(e^{S_{n-j}} 1_{\{S_i \in [\frac{\theta_i}{n} - \lambda n^{1/3} + v, \frac{\theta_i}{n} + \lambda n^{1/3} + v], \forall 0 \leq i \leq n-j\}}\right)
\]

\[
\leq e^{\theta(n-j)n^{-2/3} + \lambda n^{1/3}} \sup_{u \in [0, \lambda n^{1/3}]} \mathbb{P}\left\{ \frac{\theta_i}{n^{2/3}} - \lambda n^{1/3} + v \leq S_i \leq \frac{\theta_i}{n^{2/3}} + v, \forall 0 \leq i \leq n-j \right\},
\]

16
We now use the same trick as in the proof of the upper bound in Theorem 1.2 by sending $n$ to infinity along a subsequence. Fix an integer $N \geq 1$. Let $n := Nk$, with $k \geq 1$. For any $j \in [(\ell - 1)k + 1, \ell k] \cap \mathbb{Z}$ (with $1 \leq \ell \leq N$), we have

$$h_{j,n} \leq e^{\theta(N-\ell+1)kn^{-2/3} + \lambda n^{-1/3}} \sup_{v \in [0, \lambda n^{-1/3}]} P \left\{ v - \lambda n^{-1/3} \leq S_i - \frac{\theta_i}{n^{2/3}} \leq v, \forall i \leq (N-\ell)k \right\}.$$ 

Unfortunately, the interval $[0, \lambda n^{-1/3}]$ in $\sup_{v \in [0, \lambda n^{-1/3}]} P \{ \cdots \}$ is very large, so we split it into smaller ones of type $[(m-1)\lambda n^{-1/3}, m\lambda n^{-1/3}]$ (for $1 \leq m \leq N$), to see that the $\sup_{v \in [0, \lambda n^{-1/3}]} P \{ \cdots \}$ expression is

$$\leq \max_{1 \leq m \leq N} P \left\{ \frac{(m-1)\lambda n^{-1/3}}{N} - \lambda n^{-1/3} \leq S_i - \frac{\theta_i}{n^{2/3}} \leq \frac{m\lambda n^{-1/3}}{N}, \forall i \leq (N-\ell)k \right\}$$

$$= \max_{1 \leq m \leq N} P \left\{ -\frac{(N-m+1)\lambda}{N^{2/3}} \leq S_i - \frac{\theta i}{N^{2/3} k} \leq \frac{m\lambda}{N^{2/3}}, \forall i \leq (N-\ell)k \right\}.$$

We are now entitled to apply (2.12) to $n := (N-\ell)k$, $g_1(t) := \frac{\theta (N-\ell)kn^{-2/3}t - \frac{\theta}{(N-\ell)k^{2/3}N^{2/3}}}{(N-\ell)k^{2/3}N^{2/3}t}$ and $g_2(t) := \frac{\theta}{(N-\ell)k^{2/3}N^{2/3}t} + \frac{\theta t}{(N-\ell)k^{2/3}N^{2/3}}$, to see that for any $1 \leq \ell \leq N$ and uniformly in $j \in [(\ell - 1)k + 1, \ell k] \cap \mathbb{Z}$ (and in $j = 0$, which formally corresponds to $\ell = 0$),

$$\limsup_{k \to \infty} \frac{1}{N^{1/3}k^{1/3}} \log h_{j,Nk} \leq \theta \frac{(N-\ell+1)N}{N} + \lambda - \frac{\pi^2 \sigma^2 (N-\ell)}{2 (N+1)^2 \lambda^2},$$

which is bounded by $\frac{\theta (N+1)}{N} + \lambda - \frac{\pi^2 \sigma^2 N^2}{2 (N+1)^2 \lambda^2}$. As a consequence,

$$\limsup_{k \to \infty} \frac{1}{N^{1/3}k^{1/3}} \log \sum_{j=0}^{n} h_{j,Nk} \leq \theta \frac{(N+1)}{N} + \lambda - \frac{\pi^2 \sigma^2 N^2}{2 (N+1)^2 \lambda^2} =: c(\theta, N, \lambda).$$

Going back to (4.10), we get

$$\liminf_{k \to \infty} \frac{\log g(\theta (N^{-2/3}k^{-2/3}), Nk)}{N^{1/3}k^{1/3}} \geq \theta_1 - \frac{\pi^2 \sigma^2}{2 \lambda_1^2} - c(\theta, N, \lambda).$$

By the monotonicity of $n \mapsto g(\theta n^{-2/3}, n)$, we obtain:

$$\liminf_{n \to \infty} \frac{\log g(\theta n^{-2/3}, n)}{n^{1/3}} \geq \theta_1 - \frac{\pi^2 \sigma^2}{2 \lambda_1^2} - c(\theta, N, \lambda).$$

Sending $N \to \infty$, $\theta_1 \to \theta$, $\lambda \to \frac{\pi \sigma}{(2\theta)^{1/2}}$ and $\lambda_1 \to \frac{\pi \sigma}{(2\theta)^{1/2}}$ (in this order) completes the proof of Lemma 4.6. ⊓⊔

We now have all the ingredients for the proof of the lower bound in Theorem 1.2.
Proof of Theorem 1.2: the lower bound. Fix constants $0 < \alpha < 1$ and $b > \max\{\frac{M}{1-\alpha}; \frac{(3\pi\sigma)^2}{\alpha(\log\vartheta)^2}\}$.

Let $n > 1$. Let
\[\varepsilon = \varepsilon(n) := \frac{b}{n^{2/3}}, \quad L = L(n) := n - \lfloor n^{1/3} \rfloor.\]

Then $(1-\alpha)\varepsilon L \geq M(n - L)$ for all sufficiently large $n$, say $n \geq n_0$.

Consider the moment generating function of the reproduction distribution in the Galton–Watson tree $\mathbb{G}_{n,\varepsilon}$:
\[f(s) := \mathbb{E}(s^{\#G_{n,\varepsilon}}), \quad s \in [0, 1].\]

It is well-known that $q_{n,\varepsilon}$, the extinction probability of $\mathbb{G}_{n,\varepsilon}$, satisfies $q_{n,\varepsilon} = f(q_{n,\varepsilon})$. Therefore, for any $0 < r < \min\{q_{n,\varepsilon}, \frac{1}{16}\}$,
\[q_{n,\varepsilon} = f(0) + \int_0^{q_{n,\varepsilon}} f'(s) \, ds = f(0) + \int_0^{q_{n,\varepsilon}} f'(s) \, ds + \int_{q_{n,\varepsilon}} f'(s) \, ds.\]

Since $s \mapsto f'(s)$ is non-decreasing on $[0, 1]$, we have $\int_0^{q_{n,\varepsilon}} f'(s) \, ds \leq f'(1-r)$. On the other hand, since $f'(s) \leq f'(q_{n,\varepsilon}) \leq 1$ for $s \in [0, q_{n,\varepsilon}]$, we have $\int_{q_{n,\varepsilon}} f'(s) \, ds \leq r$. Therefore,
\[q_{n,\varepsilon} \leq f(0) + f'(1-r) + r.\]

Of course, $f(0) = \mathbb{P}\{G_{n,\varepsilon} = \emptyset\}$, whereas $f'(1-r) = \mathbb{E}[(\#G_{n,\varepsilon})(1-r)^{\#G_{n,\varepsilon}-1}]$, which is bounded by $\frac{1}{1-r} \mathbb{E}[(\#G_{n,\varepsilon})e^{-r\#G_{n,\varepsilon}}]$ (using the elementary inequality $1-u \leq e^{-u}$ for $u \geq 0$). This leads to (recalling that $r < \frac{1}{16} < \frac{1}{2}$):
\[1 - q_{n,\varepsilon} \geq \mathbb{P}\{G_{n,\varepsilon} \neq \emptyset\} - 2\mathbb{E}[(\#G_{n,\varepsilon})e^{-r\#G_{n,\varepsilon}}] - r.\]

Since $u \mapsto ue^{-ru}$ is decreasing on $[\frac{1}{r}, \infty)$, we see that $\mathbb{E}[(\#G_{n,\varepsilon})e^{-r\#G_{n,\varepsilon}}]$ is bounded by $\mathbb{E}[(\#G_{n,\varepsilon})e^{-r\#G_{n,\varepsilon}} 1_{\{\#G_{n,\varepsilon} \leq r^{-2}\}}] + r^{-2}e^{-1/r} \leq r^{-2}\mathbb{P}\{1 \leq \#G_{n,\varepsilon} \leq r^{-2}\} + r^{-2}e^{-1/r}$. Accordingly,
\[1 - q_{n,\varepsilon} \geq \mathbb{P}\{G_{n,\varepsilon} \neq \emptyset\} - \frac{2}{r^2} \mathbb{P}\{1 \leq \#G_{n,\varepsilon} \leq r^{-2}\} - \frac{2e^{-1/r}}{r^2} - r \geq \frac{1}{2} \varrho(\alpha\varepsilon, n) - \frac{2}{r^2} \mathbb{P}\{1 \leq \#G_{n,\varepsilon} \leq r^{-2}\} - 2r,\]

the last inequality following from Lemma 4.3 and the fact that $\sup_{0 < r < \frac{1}{16}} \frac{1}{r^6}e^{-1/r} < \frac{1}{2}$.

We choose $r := \frac{1}{16} \varrho(\alpha\varepsilon, n)$. [Since $\varrho(\varepsilon) \geq 1 - q_{n,\varepsilon}$, whereas $\lim_{\varepsilon \to 0} \varrho(\varepsilon) = 0$ (proved in Section 3), we have $q_{n,\varepsilon} \to 1$ for $n \to \infty$, and thus the requirement $0 < r < \min\{q_{n,\varepsilon}, \frac{1}{16}\}$ is satisfied for all sufficiently large $n$.]

\[\text{6Without further mention, the value of } n_0 \text{ can change from line to line when other conditions are to be satisfied.}\]
By Lemma 4.6, \( r^{-2} \leq \vartheta^{n-L} \) for all \( n \geq n_0 \) (because \( \frac{2n\sigma}{(2b)^{1/2}} < \log \vartheta \) by our choice of \( b \)). Therefore, an application of Lemma 4.4 tells us that for \( n \geq n_0 \), \( \Pr\{1 \leq \#G_{n,\varepsilon} \leq r^{-2}\} \leq \frac{1}{\vartheta^{n-L}} \), which, by Lemma 4.4 again, is bounded by \( r^3 \) (because \( \frac{3n\sigma}{(2b)^{1/2}} < \log \vartheta \)). Consequently, for all \( n \geq n_0 \),
\[
1 - q_{n,\varepsilon} \geq \frac{1}{2} g(\alpha \varepsilon, n) - 2r - 2r = \frac{1}{4} g(\alpha \varepsilon, n).
\]
Recall that \( g(\varepsilon) \geq 1 - q_{n,\varepsilon} \). Therefore,
\[
\liminf_{n \to \infty} \frac{1}{n^{1/3}} \log g\left(\frac{b}{n^{2/3}}\right) \geq -\frac{\pi \sigma}{(2\alpha b)^{1/2}}.
\]
Since \( \varepsilon \mapsto g(\varepsilon) \) is non-increasing, we obtain:
\[
\liminf_{\varepsilon \to 0} \varepsilon^{1/2} \log g(\varepsilon) \geq -\frac{\pi \sigma}{(2\alpha)^{1/2}}.
\]
Sending \( \alpha \to 1 \) yields (4.2), and thus proves the lower bound in Theorem 1.2.

\[\square\]

5 Appendix. Proof of Lemma 2.1

We write \( S_j(n) := \sum_{i=1}^{j} X_i(n) \) (for \( 1 \leq j \leq n \)) and \( S_0(n) := 0 \). We need to prove the lower bound in (2.13), and the upper bound in (2.12).

Lower bound in (2.13). We want to prove that for any \( b > 0 \),
\[
\liminf_{n \to \infty} \frac{a_n^2}{n} \log \Pr\left\{ E_n, \ \frac{S_n}{a_n} \geq g_2(1) - b \right\} \geq -\frac{\pi^2 \sigma^2}{2} \int_0^1 \frac{dt}{|g_2(t) - g_1(t)|^2}.
\]

Let \( g : [0, 1] \to \mathbb{R} \) be a continuous function such that \( g_1(t) < g(t) < g_2(t) \) for all \( t \in [0, 1] \). It suffices to prove the lower bound in (2.13) when \( b > 0 \) is sufficiently small; so we assume, without loss of generality, that \( g(1) \geq g_2(1) - b \).

Let \( \delta > 0 \) be such that
\[
g(t) - g_1(t) > 3\delta, \quad g_2(t) - g(t) > 9\delta, \quad \forall t \in [0, 1].
\]

Let \( A \) be a sufficiently large integer such that
\[
\sup_{0 \leq s \leq t \leq 1: \ t-s \leq \frac{3}{A}} (|g_1(t) - g_1(s)| + |g(t) - g(s)| + |g_2(t) - g_2(s)|) \leq \delta.
\]

Let \( r_n := \lfloor Aa_n^2 \rfloor \), \( N = N(n) := \lfloor \frac{n}{r_n} \rfloor \). Let \( m_N := n \) and \( m_k := kr_n \) for \( 0 \leq k \leq N - 1 \).
Since \( g(1) \geq g_2(1) - b \), we have, by definition,

\[
P \left\{ E_n, \frac{S^{(n)}_n}{a_n} \geq g_2(1) - b \right\} \geq P \left( \bigcap_{k=1}^{N} \left\{ g_1 \left( \frac{i}{n} \right) \leq \frac{S^{(n)}_i}{a_n} \leq g_2 \left( \frac{i}{n} \right), \forall i \in (m_{k-1}, m_k) \cap \mathbb{Z}, \right. \right.
\]

\[
\left. \left. g \left( \frac{m_k}{n} \right) \leq \frac{S^{(n)}_{m_k}}{a_n} \leq g \left( \frac{m_k}{n} \right) + 6\delta \right\} \right).
\]

Applying the Markov property successively at times \( m_{N-1}, m_{N-2}, \ldots, m_1 \), we obtain, by writing \( y_k := g \left( \frac{m_k}{n} \right) \) for \( 1 \leq k \leq N \),

\[
P \left\{ E_n, \frac{S^{(n)}_n}{a_n} \geq g_2(1) - b \right\} \geq p_{1,n}(0) \times \prod_{k=2}^{N} \inf_{y \in [y_{k-1}, y_{k-1} + 6\delta]} p_{k,n}(y),
\]

where\(^{7}\) for \( 1 \leq k \leq N \) and \( y \in \mathbb{R} \),

\[
p_{k,n}(y) := P \left\{ \alpha_{i,k,n} \leq \frac{S^{(n)}_i}{a_n} + y \leq \beta_{i,k,n}, \forall i \leq \Delta_k; y_k \leq \frac{S^{(n)}_{\Delta_k}}{a_n} + y \leq y_k + 6\delta \right\},
\]

\[
\alpha_{i,k,n} := g_1 \left( \frac{i + m_{k-1}}{n} \right), \quad \beta_{i,k,n} := g_2 \left( \frac{i + m_{k-1}}{n} \right), \quad \Delta_k := m_k - m_{k-1}.
\]

Uniform continuity of \( g \) guarantees that when \( n \) is sufficiently large, \( |y_k - y_{k-1}| \leq \delta \) (for all \( 1 \leq k \leq N \), with \( y_0 := 0 \)). In the rest of the proof, we will always assume that \( n \) is sufficiently large, say \( n \geq n_0 \), with \( n_0 \) depending on \( A \) and \( \delta \).

We need to bound \( p_{1,n}(0) \times \prod_{k=2}^{N} \inf_{y \in [y_{k-1}, y_{k-1} + 6\delta]} p_{k,n}(y) \) from below. Let us first get rid of the infimum \( \inf_{y \in [y_{k-1}, y_{k-1} + 6\delta]} p_{k,n}(y) \), which is the minimum between \( \inf_{y \in [y_{k-1}, y_{k-1} + 3\delta]} \) and \( \inf_{y \in [y_{k-1} + 3\delta, y_{k-1} + 6\delta]} \):\(^{7}\)

\[
\inf_{y \in [y_{k-1}, y_{k-1} + 6\delta]} p_{k,n}(y) \geq \min \{ p^{(1)}_{k,n}, p^{(2)}_{k,n} \}, \quad n \geq n_0, \ 2 \leq k \leq N,
\]

where, for \( 1 \leq k \leq N \),

\[
p^{(1)}_{k,n} := P \left\{ \alpha_{i,k,n} - y_{k-1} \leq \frac{S^{(n)}_i}{a_n} \leq \beta_{i,k,n} - y_{k-1} - 3\delta, \forall i \leq \Delta_k; \delta \leq \frac{S^{(n)}_{\Delta_k}}{a_n} \leq 2\delta \right\},
\]

\[
p^{(2)}_{k,n} := P \left\{ \alpha_{i,k,n} - y_{k-1} - 3\delta \leq \frac{S^{(n)}_i}{a_n} \leq \beta_{i,k,n} - y_{k-1} - 6\delta, \forall i \leq \Delta_k; -2\delta \leq \frac{S^{(n)}_{\Delta_k}}{a_n} \leq -\delta \right\}.
\]

And, of course, \( p_{1,n}(0) \geq p^{(1)}_{1,n} \geq \min \{ p^{(1)}_{1,n}, p^{(2)}_{1,n} \} \). We arrive at the following estimate:

\[
P \left\{ E_n, \frac{S^{(n)}_n}{a_n} \geq g_2(1) - b \right\} \geq \prod_{k=1}^{N} \min \{ p^{(1)}_{k,n}, p^{(2)}_{k,n} \} = \min \{ p^{(1)}_{N,n}, p^{(2)}_{N,n} \} \prod_{k=1}^{N-1} \min \{ p^{(1)}_{k,n}, p^{(2)}_{k,n} \}.
\]

\(^{7}\)For notational simplification, we write \( \forall i \leq \Delta_k \) instead of \( \forall i \in (0, \Delta_k] \cap \mathbb{Z} \).
First, we bound \( p^{(1)}_{k,n} \) and \( p^{(2)}_{k,n} \) from below, for \( 1 \leq k \leq N - 1 \) (in which case \( \Delta_k = r_n \)). We split the indices \( k \in (0, N - 1] \cap \mathbb{Z} \) into \( A \) blocs, by means of \( (0, N - 1] \cap \mathbb{Z} = \bigcup_{j=1}^A J_j \), where \( J_j = J_j(n) := \left( \frac{(j-1)(N-1)}{A}, \frac{j(N-1)}{A} \right] \cap \mathbb{Z} \). For indices \( k \) lying in a same bloc \( J_j \), we use a common lower bound for \( \min\{p^{(1)}_{k,n}, p^{(2)}_{k,n}\} \) as follows: assuming \( k \in J_j \), we have, by (5.2), \( \alpha_{i,k,n} \leq g_1(\frac{k}{A}) + \beta_{i,k,n} \geq g_2(\frac{k}{A}) - \delta \) (for \( n \geq n_0 \) and \( i \leq r_n \)), and \( |y_{k-1} - g(\frac{k}{A})| \leq \delta \), which leads to: \( p^{(1)}_{k,n} \geq q^{(1)}_{i,k,n} \), and \( p^{(2)}_{k,n} \geq q^{(2)}_{i,k,n} \) (for \( n \geq n_0, 1 \leq \ell \leq A \) and \( k \in J_j \)), where (recalling that \( \Delta_k = r_n \) for \( 1 \leq k \leq N - 1 \))

\[
q^{(1)}_{i,k,n} := \mathbb{P}\left\{ g_1\left(\frac{\ell}{A}\right) - g\left(\frac{\ell}{A}\right) + 2\delta \leq \frac{S^{(n)}_{i}}{a_n} \leq g_2\left(\frac{\ell}{A}\right) - g\left(\frac{\ell}{A}\right) - 5\delta, \ \forall i \leq r_n; \ \delta \leq \frac{S^{(n)}_{r_n}}{a_n} \leq 2\delta \right\},
q^{(2)}_{i,k,n} := \mathbb{P}\left\{ g_1\left(\frac{\ell}{A}\right) - g\left(\frac{\ell}{A}\right) - \delta \leq \frac{S^{(n)}_{i}}{a_n} \leq g_2\left(\frac{\ell}{A}\right) - g\left(\frac{\ell}{A}\right) - 8\delta, \ \forall i \leq r_n; -2\delta \leq \frac{S^{(n)}_{r_n}}{a_n} \leq -\delta \right\}.
\]

Therefore,

\[
\mathbb{P}\left\{ E_n, \frac{S^{(n)}_{n}}{a_n} \geq g_2(1) - b \right\} \geq \min\left\{ p^{(1)}_{N,n}, p^{(2)}_{N,n} \right\} \prod_{\ell=1}^A \min\{ q^{(1)}_{i,k,n}, q^{(2)}_{i,k,n} \} \#J_j.
\]

Since \( \#J_j \leq \frac{N}{A} \leq \frac{n}{r_n A} \leq \frac{n}{(Aa_n^2 - 1)A} \), this yields

\[
(5.3) \quad \mathbb{P}\left\{ E_n, \frac{S^{(n)}_{n}}{a_n} \geq g_2(1) - b \right\} \geq \min\left\{ p^{(1)}_{N,n}, p^{(2)}_{N,n} \right\} \prod_{\ell=1}^A \left( \min\{ q^{(1)}_{i,k,n}, q^{(2)}_{i,k,n} \} \right)^{n/(Aa_n^2 - 1)A}.
\]

It is well-known that the linear interpolation function \( t(\in [0,1]) \rightarrow \frac{1}{n} \{ S^{(n)}_{r_n t} + (r_n t - [r_n t])X^{(n)}_{[r_n t]} \} \) converges in law to \( (\sigma \sqrt{A} W_t, 0 \leq t \leq 1) \), where \( W \) denotes a standard one-dimensional Brownian motion.\(^8\) So, if we write

\[
f(a,b,c,d) := \mathbb{P}\left\{ a \leq W_t \leq b, \ \forall t \in [0,1]; \ c \leq W_1 \leq d \right\},
\]

for \( a < 0 < b \) and \( a \leq c < d \leq b \), then for any \( 1 \leq \ell \leq A \),

\[
\lim_{n \to \infty} q_{i,k,n}^{(1)} = f\left( \frac{g_1(\frac{k}{A}) - g(\frac{k}{A}) + 2\delta}{\sigma A^{1/2}}, \frac{g_2(\frac{k}{A}) - g(\frac{k}{A}) - 5\delta}{\sigma A^{1/2}} \right), \quad \lim_{n \to \infty} q_{i,k,n}^{(2)} = f\left( \frac{g_1(\frac{k}{A}) - g(\frac{k}{A}) - \delta}{\sigma A^{1/2}}, \frac{g_2(\frac{k}{A}) - g(\frac{k}{A}) - 8\delta}{\sigma A^{1/2}} \right).
\]

[Thanks to (5.1), the limits are (strictly) positive.] The function \( f \) is explicitly known (see for example, Itô and McKean [10], p. 31):

\[
(5.4) \quad f(a,b,c,d) = \int_c^d \frac{2}{b-a} \sum_{n=1}^\infty \exp\left( - \frac{n^2 \pi^2}{2(b-a)^2} \right) \sin\left( \frac{n \pi |a|}{b-a} \right) \sin\left( \frac{n \pi (z-a)}{b-a} \right) \, dz,
\]

\(^{8}\)In fact, finite-dimensional convergence is easily obtained by verifying Lindeberg’s condition in the central limit theorem, whereas tightness is checked using a standard argument, see for example Billingsley [4].
from which it is easily seen that for all \( A \) sufficiently large, say \( A \geq A_0 \) (\( A_0 \) depending on \( \delta \)), uniformly in \( 1 \leq \ell \leq A \),

\[
\lim_{n \to \infty} q_{\ell,n}^{(1)} \geq \exp \left( -\frac{\sigma^2}{2} \frac{\pi^2}{[g_2(\ell^2) - g_1(\ell^2) - 7\delta]^2} \right),
\]

\[
\lim_{n \to \infty} q_{\ell,n}^{(2)} \geq \exp \left( -\frac{\sigma^2}{2} \frac{\pi^2}{[g_2(\ell^2) - g_1(\ell^2) - 7\delta]^2} \right).
\]

Similarly, we have a lower bound for \( \min\{p_{N,n}^{(1)}, p_{N,n}^{(2)}\} \), the only difference being that \( \Delta_N \) is not exactly \( \tilde{r}_n \) but lies somewhere between \( r_n \) and \( 2r_n \). This time, we only need a rough estimate: there exists a constant \( C > 0 \) such that

\[
\liminf_{n \to \infty} \min\{p_{N,n}^{(1)}, p_{N,n}^{(2)}\} \geq C.
\]

In view of (5.3), we get that, for all \( A \) sufficiently large (how large depending on \( \delta \)),

\[
\liminf_{n \to \infty} \frac{a_n^2}{n} \log \mathbb{P} \left\{ E_n, \frac{S_n^{(n)}}{a_n} \geq g_2(1) - b \right\} \geq -\frac{\sigma^2}{2} \frac{\pi^2}{A} \sum_{\ell=1}^{A} \frac{1 + \delta}{[g_2(\ell^2) - g_1(\ell^2) - 7\delta]^2}
\]

\[
\geq -\frac{\sigma^2}{2} \left( 1 + 2\delta \right) \int_0^1 \frac{dt}{[g_2(t) - g_1(t) - 7\delta]^2}.
\]

Letting \( A \to \infty \) and \( \delta \to 0 \) (in this order), we obtain the desired lower bound in (2.13). \( \square \)

**Upper bound in (2.12).** The upper bound in (2.12) is needed in this paper only in the form of the original result of Mogulskii [18] (i.e., for sequences, instead of arrays, of random variables). We include its proof for the sake of completeness. It is similar to, and easier than, the proof of the lower bound in (2.13).

Let \( g \) be as before. Let \( \delta > 0 \) and \( A > 0 \) satisfy again (5.1) and (5.2), respectively. Let again \( r_n := [Aa_n^2] \), \( N = N(n) := [\frac{n}{r_n}] \). Let \( m_k := kr_n \) for \( 0 \leq k \leq N - 1 \), but we are not interested in \( m_N \) any more. Write again \( \alpha_{i,k,n} := g_1(\frac{1 + m_k - 1}{n}) \) and \( \beta_{i,k,n} := g_2(\frac{1 + m_k - 1}{n}) \).

By the Markov property,

\[
\mathbb{P}(E_n) \leq \prod_{k=2}^{N-1} \sup_{y \in [g_1(\frac{m_k-1}{n}), g_2(\frac{m_k-1}{n})]} \tilde{p}_{k,n}(y),
\]

where

\[
\tilde{p}_{k,n}(y) := \mathbb{P}\left\{ \alpha_{i,k,n} \leq \frac{S_i^{(n)}}{a_n} + y \leq \beta_{i,k,n}, \forall 0 < i \leq r_n \right\}.
\]
Since \( g_1 \) and \( g_2 \) are bounded, we know that \( g_1(\frac{m_{k-1}}{n}) \) and \( g_2(\frac{m_{k-1}}{n}) \) lie in a compact interval, say \([-K\delta, K\delta] \) (\( K \) being an integer depending on \( \delta \)). Therefore

\[
\sup_{y \in [g_1(\frac{m_{k-1}}{n}), g_2(\frac{m_{k-1}}{n})]} \tilde{p}_{k,n}(y) \leq \max_{j \in [-K, K-1] \cap \mathbb{Z}} \sup_{y \in \{j\delta, j\delta+1\}} \tilde{p}_{k,n}(y).
\]

As in the proof of the lower bound in (2.13), we cut the interval \((1, N-1] \cap \mathbb{Z}\) into \( A \) blocs, by means of \((1, N-1] \cap \mathbb{Z} = \cup_{\ell=1}^{A} J_{\ell}\), where \( J_{\ell} = J_{\ell}(n) := (\frac{(\ell-1)(N-2)}{A}, \frac{(\ell)(N-2)}{A} + 1] \cap \mathbb{Z} \). For \( k \in J_{\ell} \), we have, by (5.2), \( \alpha_{i,k,n} \geq g_1(\frac{\ell}{A}) - \delta \) and \( \beta_{i,k,n} \leq g_2(\frac{\ell}{A}) + \delta \), which leads to:

\[
\tilde{q}_{\ell,n}(j) := \mathbb{P}\left\{ g_1(\frac{\ell}{A}) - (j + 2)\delta \leq \frac{S_1(n)}{a_n} \leq g_2(\frac{\ell}{A}) - (j - 1)\delta, \forall i \leq r_n \right\}.
\]

Therefore,

\[
\mathbb{P}(E_n) \leq \prod_{\ell=1}^{A} \left[ \max_{j \in [-K, K] \cap \mathbb{Z}} \tilde{q}_{\ell,n}(j) \right]^{\#J_{\ell}}.
\]

We have \( \#J_{\ell} \geq \frac{N-2}{A} - 1 \geq \frac{n}{A^2\sigma^2} - \frac{3}{4} - 1 \). On the other hand, for each pair \((\ell, j)\), \( \tilde{q}_{\ell,n}(j) \) converges (as \( n \to \infty \)) to \( \mathbb{P}\{g_1(\frac{\ell}{A}) - (j + 2)\delta \leq \sigma A^{1/2} W_t \leq g_1(\frac{\ell}{A}) - (j - 1)\delta, \forall t \in [0, 1]\} \), which, in view of (5.4), is bounded by \( \exp\left\{ -\frac{\pi^2\sigma^2}{2} \frac{(1-\delta)A}{[g_2(\ell/A) - g_1(\ell/A) - 3\delta]} \right\} \) for all sufficiently large \( A \) and uniformly in \((\ell, j)\). Accordingly,

\[
\limsup_{n \to \infty} \frac{a^2}{n} \log \mathbb{P}(E_n) \leq \frac{\pi^2\sigma^2}{2} \sum_{\ell=1}^{A} \frac{1 - \delta}{[g_2(\frac{\ell}{A}) - g_1(\frac{\ell}{A}) - 3\delta]^2} \leq \frac{\pi^2\sigma^2}{2} (1 - 2\delta) \int_0^1 \frac{dt}{[g_2(t) - g_1(t) - 3\delta]^2},
\]

for all sufficiently large \( A \). Since \( \delta \) can be as close to 0 as possible, this yields the upper bound in (2.12).

\[\square\]
