Abstract
Introduction: Advancing age, comorbidity, and financial burden have been observed in chronic hepatitis B (CHB) patients globally. As Japan is leading the world in aging demographics, similar real-world data are urgently needed for its CHB population to inform all stakeholders. Methods: This cross-sectional study characterized the demographics, comorbidities, and healthcare costs of a large Japanese real-world adult (≥18 years) CHB patient (ICD-10: B18.1) population from the Medical Data Vision database from January 01, 2012, to December 31, 2016. Comorbidities were identified by ICD-10 codes, and the annual point prevalence and Charlson Comorbidity Index (CCI) score were calculated. Annual mean and median all-cause healthcare utilization and costs per patient were calculated. Comparison tests were conducted for CCI scores, prevalence of comorbidities, and healthcare resource utilization and costs. Results: We identified 11,125 CHB patients. Between 2012 and 2016, the mean age increased from 62.0 to 65.2 years, and the percentage of those aged ≥65 years increased from 45.6% to 60.7%. The prevalence of cirrhosis remained similar (5.8% in 2012 and 5.6% in 2016, \( p = 0.69 \)) while hepatocellular carcinoma decreased from 6.3% to 4.5% (\( p < 0.01 \)). The prevalence of non-liver comorbidities increased (40.9–52.0% for cancer \( p < 0.01 \), 12.1–17.7% for osteoporosis \( p < 0.01 \), and 10.7–15.0% for renal impairment \( p < 0.01 \)). Healthcare resource utilization and costs also increased, with a 119.3% increase in median total healthcare costs from JPY 229,143 in 2012 to 502,467 in 2016 (\( p < 0.01 \)). Conclusions: The CHB population of Japan is predominantly elderly and carry a high nonliver comorbidity burden, while incurring increasing healthcare costs.

Introduction
Chronic hepatitis B virus (HBV) infection leads to cirrhosis and hepatocellular carcinoma (HCC) and affected 257 million people worldwide in 2015 [1]. In Japan, the
estimated prevalence of HBV infection was 0.6% in 2016 while the total estimated CHB population included 719,000 people [2]. In 2019, the estimated number of deaths attributed to HBV infection in Japan was between 6,475 and 8,750 [3].

In the year 2000, almost 80% of the total Japan CHB population were 40 years of age or older while in 2016, the prevalence of HBV infection in Japanese children was very low (0.033%). These findings probably resulted from the institution of a selective program providing hepatitis B immune globulin and hepatitis B vaccination for infants born to hepatitis B surface antigen-positive mothers in 1986, since the Japanese government only introduced universal hepatitis B vaccination for infants in 2016 [4, 5].

This unique distribution of Japan’s CHB population results from Japan having one of the highest life expectancy and the lowest birth rates in the world [6, 7]. As the general population of Japan continues to age (36 million or 28% out of the total 126 million in 2019 being 65 years or older), the Japan CHB population is also likely to be aging [8]. Thus, the high proportion of elderly people in Japan highlights the importance of assessing and controlling healthcare utilization and expenditures in Japan, a country with the third largest economy and the eleventh most populous in the world [9–11].

Apart from the liver-related sequelae of CHB, nonliver comorbidities are additional concerns that can complicate the clinical management of an aging CHB population. As recently shown by a healthcare claims database study in the USA, the mean age of the CHB population in the USA increased from 48 to 52 years between 2006 and 2015, with an increased prevalence of multiple comorbidities including cardiovascular diseases (CVD), diabetes, hyperlipidemia, renal impairment, and bone-related diseases alongside increased healthcare resource utilization and cost [12]. In addition, compared to age- and sex-matched non-CHB controls, CHB patients were found to have a higher cumulative incidence of chronic kidney disease, which was also observed in a prior study using the Taiwan National Insurance database [12–14]. However, data characterizing the real-world CHB population in Japan are limited.

Therefore, to assist clinical sectors in the management of the aging CHB population and inform other stakeholders to guide public health efforts and government resource allocation, we aimed to examine the demographics, prevalence of liver and nonliver comorbidities, healthcare resource utilization, and costs as well as their changes over time in a large nationwide real-world cohort of CHB patients in Japan using the Medical Data Vision database (MDV, Tokyo, Japan) [15].

### Materials and Methods

#### Study Design
We performed a retrospective cross-sectional analysis of CHB patients in Japan using the MDV claims database from April 2008 to March 2017. Since 2008, the MDV database has collected monthly data on inpatient, outpatient, and pharmacy claims in addition to disease-procedure combination claims. As of 2017, the MDV database included approximately 300 hospitals (inclusive of acute inpatient care and routine outpatient ambulatory care), covering >20 million patients across Japan [15].

In our study, 2 subsets from the MDV database were used: Act data (containing information on treatment and procedures) and Disease data (containing information on diagnosed diseases). From these 2 datasets, we identified a total of 86,234 patients with CHB between April 2008 and March 2017. Data in this period were used to determine eligibility of patients; however, the analyses were conducted on data between January 2012 and December 2016. Data prior to 2012 were excluded due to small patient numbers, and data from 2017 were excluded as only the first 3 months of the calendar year were available.

#### Study Population

The study included adult patients who had at least 1 record of CHB (ICD-10: B18.1) and were aged 18 years or older at their index date, that is, date of the first visit with a CHB diagnosis. Patients were excluded if they had hepatitis C, hepatitis D, or human immunodeficiency virus coinfection; hepatitis B patients receiving interferon-based therapy were also excluded due to the potential for the treatment-related adverse events to skew the comorbidity and healthcare resource utilization analyses. Patients who received nucleos(t)ide analog therapy (whether treatment naïve or experienced at study entry) were eligible for inclusion. Patients must have had at least 1 claim for any disease, treatment, or procedure in the 6 months pre-index and post-index dates to ensure that patients included in the study accessed the healthcare system during the study duration. Online suppl. Table 1 (for all online suppl. material, see www.karger.com/doi/10.1159/000515854) describes further details of the inclusion and exclusion criteria of the study.

#### Outcome Measures

Outcome measures included demographic characteristics (gender and age), diagnoses of comorbidities by ICD-10 codes, total all-cause healthcare resource utilization, and healthcare costs. All analyses were summarized by the calendar year (2012–2016). Patients were included in each year if they had at least 1 claim in either Act data or Disease data in the years during or after the index date.

For the demographic analyses, we extracted gender and age from the sex and age variables, respectively. We reported mean age with standard deviation (SD) in each year. We also reported age groups based on the age at their index date or first claim in that particular year (18–34, 35–44, 45–54, 55–64, 65–74, and ≥75 years) and gender distribution in percentages. Patients aged ≥ 65 years were considered elderly [16].

We assessed the overall comorbidity burden of the study cohort via the Charlson Comorbidity Index (CCI) using ICD-10 codes for each patient from Disease data [17]. CCI scores can range from 0 to 28, with a higher number indicating a poorer health state. CCI scores were summed and divided by the number of patients to cal-
calculate the mean, per-patient CCI score for each year, accompanied by the SD. The median and interquartile range (IQR) were also reported for each year. We also assessed the prevalence of 47 pre-selected comorbidities, based on ICD-10 codes [18, 19]. With regard to bone fracture data, patients may have both pathological and nonpathological bone fractures within a year and therefore be included separately in these subgroups, but only counted once in the “bone fracture (all)” category.

We assessed all-cause healthcare resource utilization and costs for each calendar year using derivations in Act data (online suppl. Table 2). In brief, we assessed the per-patient, per-year, all-cause healthcare resource utilization for each calendar year as given below. Patients who had no claim for any of these healthcare visits were assumed to have not utilized that resource:

- Number of patients with at least 1 inpatient admission.
- Mean, SD, median, and IQR of the number and duration of inpatient admissions.
- Number of patients with at least 1 outpatient visit to the hospital.
- Mean, SD, median, and IQR of the number of outpatient visits.

For all-cause healthcare costs, we calculated the per-patient, per-year, mean, SD, median, and IQR of total and yearly healthcare costs, as well as costs of inpatient visit, outpatient visit, pharmacy or medication use, and diagnostic tests (including imaging, pathology, and laboratory tests) for each calendar year by adding up the cost reported for each patient and then dividing this sum by the number of patients who had claims in that calendar year. We categorized inpatient or outpatient resources based on the claims code assigned for each procedure within the MDV database (online suppl. Table 2). Inpatient costs refer to any costs associated with an inpatient stay in the hospital, including physician fees, accommodation costs, drug costs, and diagnostic tests, similarly for outpatient costs. Pharmacy costs and diagnostic costs include costs within these categories incurred in both the inpatient and outpatient setting. We did not adjust for inflation as the Japanese core inflation rate was approximately 0.7% between 2012 and 2016 [20].

Comparison tests were conducted for CCI scores, prevalence of each preselected comorbidity, and healthcare resource utilization and costs to compare the differences between results in 2012 and 2016. As samples in those 2 years were neither totally independent nor totally dependent, partially overlapping comparison tests were conducted [21]. The partially overlapping t-test was used for CCI score, healthcare resource utilization, and costs while the partially overlapping z-test was used for prevalence of each preselected comorbidity. A p-value of <0.05 was considered statistically significant.

**Results**

**Patient Characteristics**

A total of 11,125 CHB patients met the eligibility criteria and were included in the analysis; the application of the exclusion criteria to derive the patient population is detailed in online suppl. Table 3. The number of patients included in each year increased substantially, predominantly reflecting increased inclusion of centers within the MDV database over time. Around half (52–54%) of the cohort were male (Table 1). The mean age of our CHB cohort increased from 62.0 years in 2012 to 65.2 years in 2016 (Table 1). The proportion of senior citizens (aged ≥65 years) increased from 45.6% in 2012 to 60.7% in 2016 (Table 1). The proportion of very elderly patients aged ≥75 years also increased from 17.0% in 2012 to 24.3% in 2016 (Table 1).

**Comorbidity Burden**

Across each calendar year, we were able to estimate CCI scores for >96% of included patients. The mean CCI score per patient increased from 4.0 in 2012 to 4.8 in 2016, while the median score increased from 3.0 to 4.0 (Fig. 1). The prevalence of the 47 selected comorbidities is presented in Table 2. From 2012 to 2016, the prevalence of

|           | 35–44 years | 7.4           | 6.9            | 6.6            | 6.1            | 5.7            |
|           | 45–54 years | 12.6          | 12.0           | 11.0           | 10.7           | 10.1           |
|           | 55–64 years | 30.7          | 28.4           | 25.5           | 21.7           | 20.5           |
|           | 65–74 years | 28.6          | 30.4           | 32.7           | 35.6           | 36.4           |
|           | ≥75 years  | 17.0          | 18.6           | 20.6           | 22.5           | 24.3           |

CHB, chronic hepatitis B; SD, standard deviation.
most comorbidities increased significantly. While total cancer cases increased significantly over time (from 40.9% to 52.0%, \( p < 0.01 \)), the prevalence of HCC decreased significantly, from 6.3% in 2012 to 4.5% in 2016 (\( p < 0.01 \)), and the prevalence of cirrhosis remained stable across the period, at 5.8% in 2012 and 5.6% in 2016 (\( p = 0.69 \)). Other liver diseases, including nonalcoholic fatty liver disease/hepatic steatosis (2012: 3.7%; 2016: 4.1%, \( p = 0.44 \)) and alcoholic liver disease/alcoholic cirrhosis/alcoholic hepatitis (2012: 1.4%; 2016: 1.7%, \( p = 0.45 \)), also remained stable.

The prevalence of osteoporosis increased significantly from 12.1% to 17.7% (\( p < 0.01 \)) over time, with significant increases also seen in the occurrence of bone fractures (3.1–4.6%, \( p = 0.01 \)). Significantly more patients experienced renal impairment in 2016 compared to 2012 (increase from 10.7% to 15.0%, \( p < 0.01 \)), driven partially by a significant increase in cases of chronic kidney disease (from 3.4% to 5.6%, \( p < 0.01 \)) (Table 2).

**All-Cause Healthcare Resource Use**

Across all calendar years, roughly one-third of CHB patients had at least 1 inpatient admission (due to any cause) and the mean, per-patient number of inpatient admissions per year increased from 0.58 in 2012 to 0.70 in 2016 (\( p < 0.01 \)) (Table 3). The mean, per-patient duration of inpatient admission increased slightly from 9 to 11 days from 2012 to 2016 (\( p = 0.09 \)). The median number of inpatient admissions and median duration of inpatient admissions were zero across all years, as two-thirds of patients were not admitted as inpatients. The vast majority (≥89%) of all CHB patients had at least 1 outpatient visit each year, and the mean per-patient number of outpatient visits per year increased from 7.4 in 2012 to 12.0 in 2016 (\( p < 0.01 \)). The median number of outpatient visits doubled in the same time period (from 4.0 in 2012 to 8.0 in 2016) (Table 3).

**All-Cause Healthcare Costs**

From 2012 to 2016, the mean total healthcare costs per patient per year increased from JPY 846,178 to 1,332,417 (\( p < 0.01 \)). The median total healthcare costs increased from JPY 229,143 to 502,467 (Table 4). In 2012 and 2013, inpatient costs represented a larger component of the total healthcare costs as compared to outpatient costs. However, by 2016, the mean outpatient cost was JPY 711,523 per patient per year, while the mean per-patient inpatient cost was JPY 621,894 (Table 4). The per-patient drug cost increased significantly between 2012 and 2016. Diagnostic costs remained the smallest cost component across all years, although these also increased significantly (Table 4).

**Discussion/Conclusion**

This large real-world analysis has helped to characterize and assess the changes over time of the demographics, comorbidities, and healthcare resource utilization and costs of CHB patients in Japan. Our study showed that the majority of CHB patients in Japan are elderly, with a mean age of 65 years and with 61% being ≥65 years old in...

2016 compared with 46% of patients in 2012. While the trend of advancing age has been observed in CHB patients from recent studies around the world, the mean age of our study population was approximately 10 to almost 16 years higher than CHB population in the USA (51.8 ± 12.4 years in 2015) and neighboring Asian countries such as Korea (49.5 ± 9.4 in 2015) and Hong Kong (55 ± 15 in 2014–2017) [12, 22, 23]. Though Japan, as a whole, has an aging population, the CHB patient population is on average substantially older than the general population: 23.4% of the population in Japan was ≥65 years old in 2012 compared with 45.6% of patients in our study for the same year [24]. This differential age distribution is likely due to the implementation of hepatitis B vaccination programs started in the late 1980s, which essentially eliminated HBV infections in patients under the age of 30.

### Table 3. All-cause healthcare resource utilization of the study population by calendar year

USA, where the majority of CHB cases are “imported” due to steady immigration from endemic countries, the immigrant population of Japan remains low at 2% over the past decade [25]. The use of antiviral treatment, which reduces the risk of disease progression (as potentially reflected by the decreasing prevalence of HCC and steady prevalence of cirrhosis observed in this study), may also help prolong the life expectancy of CHB patients and contribute to the aging of the CHB population [26–28].

Another reason for the advanced age of CHB patients in Japan and elsewhere in the world can be due to delayed screening and diagnosis, such that HBV-infected patients do not get diagnosed until later in life. Indeed, the connection to care for CHB patients is suboptimal, even in high-income countries, as illustrated by a 15% liver disease awareness rate in a recent population-based survey study and a 19% CHB diagnosis rate among 198 million Americans with private insurance [29, 30].

While the general trend in our study was an increase in the prevalence of comorbidities, we reported a decreasing trend of cirrhosis and HCC. This result is in line with other studies from Japan showing a decreasing contribution of viral hepatitis to overall national cirrhosis and HCC cases, with CHB-related cirrhosis cases dropping from 11.6% of overall cirrhosis cases in 2008 to 8.8% in 2016 [31, 32]. This may reflect improvements in CHB treatment over the past decade.

With a rapidly aging CHB population in our study, it is unsurprising that the prevalence of most nonliver comorbidities increased over time. This is an important finding for clinicians to consider during the course of the management and monitoring of these patients. In fact, our comorbidity analyses demonstrated that the mean CCI score of CHB patients in the present study increased by almost 1 point, from 4.0 in 2012 to 4.8 in 2016. In addition, as with the mean age discussed above, the mean CCI was higher among the CHB population of this study than in a 2015 study from the USA (2.6 ± 3.0 among Medicaid patients) [12].

Somewhat daunting is that by 2016, the majority of the Japanese CHB population in this study had gastroesophageal diseases (58.2%), cancer (52.0%), or CVD (52.0%) while approximately one-third had hypertension (39.1%) or diabetes (35.6%). All of these comorbidities were substantially higher than the prevalence of any malignancy, CVD, hypertension, and diabetes findings from the USA (7.3%, 11.8%, 32.0%, and 15.3%, respectively, in 2015) or Hong Kong (23.6%, 22.2%, 28.6%, and 20.1%, respectively, in 2014–2017) studies [12, 23]. The results likely reflect the particularly aged nature of the CHB population in Japan, with the hypertension prevalence (39.1%) being similar to that reported in 2016 for Japanese women aged 50–59 years (35.7%) [33]. However, the diabetes prevalence (35.6%) in our study is much higher than in the general Japanese population (8.3–16%) [34]. These discrepancies could be due to surveillance bias in which people with one chronic disease such as CHB undergo more screening and surveillance for other comorbidities.

Approximately one-quarter (25.5%) of the studied CHB population also had bone-related diseases (osteoporosis, osteoarthritis, or vitamin D deficiency) and 15.0% exhibited renal impairment of some degree. CHB patients with bone and renal disorders or patients who are at risk of such impairments may require special considerations such as medication dosage adjustment and/or avoidance of antiviral medications that can compromise bone or renal health, as per international CHB management guidelines [35, 36].

We observed an increase in resource utilization and costs in our study cohort over time, a finding that is consistent with data from other countries [37, 38]. By 2016, median all-cause healthcare costs among CHB patients in this study were JPY 502,467, translating to a 119.3% increase from JPY 229,143 in 2012. This rise in costs corresponds with a rise in the utilization of healthcare resources, including the number of both inpatient admissions and outpatient visits. However, we caution against interpretation that the rising cost was due solely to CHB, as our analysis considered all costs incurred by CHB patients, not only CHB-related costs.

Apart from the limitations already highlighted, the study has further limitations pertaining to the use of the MDV database. Despite the increasing coverage of the database, patients may have also sought care at facilities not covered by the MDV database used in this study, though this is unlikely since patients with chronic conditions tend to follow-up with their regular physician. In addition, the MDV database only covers certain medical centers that include both acute care hospitals and outpatient clinics. Thus, our analyses did not capture any resource use or costs of CHB patients managed in other types of health-care facilities such as ambulatory centers or primary care facilities, if they were not attached to acute care hospitals. Any effect is likely to be limited, as specialized medical institutions are appointed as the primary care provider for viral hepatitis patients in Japan [9]. The MDV database does not include clinical or laboratory data for the vast majority of patients; as such, we were unable to characterize the clinical and laboratory characteristics of our study population or investigate their potential associations with study outcomes. Similarly, the lack of clinical data to ad-
just for background differences between the treated and untreated groups also limited our ability to investigate the effect of antiviral therapy on study outcomes. Finally, we excluded data prior to 2012 from our study, due to unstable fluctuations in patient demographics. Nevertheless, even the 2012 data may be subject to such fluctuations, as potentially indicated by the 8% increase in patients attending outpatient visits between 2012 and 2013. Therefore, the 2012 data should be interpreted with caution.

In conclusion, the CHB patient population in Japan is elderly with an advancing mean age. Between 2012 and 2016, 61% were aged 65 years or older and 1 in 4 were aged 75 years or older by 2016. Over this time period, liver-related morbidities decreased but the nonliver comorbidity burden increased; by 2016, more than half of the study population presented with cancer or CVD, one-third with diabetes, one-third with hypertension, one-quarter with bone disorders, and 15% with renal impairment. Assessment and consideration of these highly prevalent and relevant nonliver comorbidities are important in this elderly CHB population.

Acknowledgements

Writing assistance was provided by Min Hee Choi, PhD, of Costello Medical, Singapore. Database analysis support was provided by Tristan Curteis and Amy Buchanan-Hughes of Costello Medical, UK.

Statement of Ethics

Ethics committee approval for this study was not required. Patient data in the Medical Data Vision (MDV) are deidentified at the hospital level before being incorporated into the database, and the medical claims data retrieved from the database for this study were unlinkable to individual patients. Furthermore, there was no active enrollment, interventions, follow-up, or direct data collection from individuals.
