ABSTRACT
In this paper an approximate analytical solution for mathematical model dynamic behavior of spacecraft (SC) which moves at the disturbed surface is discussed. A hybrid asymptotic approach on the basis of perturbation and phase-integral (or WKB) method have been employed to the singular nonlinear with time-variant periodic coefficients differential equation of motion in search of an approximate analytical solution.

Key words: Nonlinear dynamics, spacecraft structure, disturbed surface, hybrid asymptotic approach, approximate analytical solution.

1. INTRODUCTION
Mathematical modeling for the nonlinear dynamics of structures near the disturbed surface is an important question for a variety of problems of SC systems. Of the interest, from the point of view of the dynamic effects appearance is the case of the coupled vibrations during the fly at the optional angle, for example, to the ocean wave surface [1-3]. It should be mentioned, that existing solutions, as a rule, are reduced to the solution of Mathieu-Hill equation on the conditions that the recuperate moment has non-linear (especially cube) character [1,2] and dimensionless amplitude of the parametric excitation is a small quantity. However, in real conditions of SC system exploitation, value of this parameter can be not small, that can leads to significant lost quality of dynamic characteristics. Most interest from the point of view of origin of different dynamic effects presents the case of joint vibrations of vehicle in plane of heel and in plane of tangage. The mechanical analogue of this process can serve the model of the mathematical pendulum vibration in a vertical plane with the hesitating on the set law supporting point. This paper continues the discussions of the publications in this sphere and deals with the discussion of proposed an approximate analytical solution of the problem.

2. SINGULAR NONLINEAR DIFFERENTIAL EQUATION OF THE PROBLEM. HYBRID ASYMPTOTIC SOLUTION
Mathematical model for dynamic problem of the spacecraft-absorber system is presented on Fig. 1.

Fig. 1 – Calculation chart «SC – absorber»
Differential equation system, describing of «SC – dynamic absorber» vibration process is as follows [2]:
\[ I \frac{d^2 \gamma}{dt^2} + n \frac{d\gamma}{dt} + C_{11}(t) \gamma + C_{22}(t) \gamma^m + I x_0 \left( y + y^0 \right) = 0, \]
\[ I \gamma_0 \left( y + y^0 \right) + n_0 \gamma_0^m(t) + C_1 y_0(t) + C_2 \gamma^m(t) = F \left( y^0, t \right) \] (2)

With due regard to the second equation of the system (1) the main differential equation of tangage motion acquires the form

\[ I \gamma(t) + n_0 \gamma^0(t) + C_{11} \gamma(t) + C_{22} \gamma^m(t) = F \left( y^0, t \right) \]

where

\[ F \left( y^0, t \right) = n_0 \gamma^0(t) + C^0 \gamma^0(t), \]

\[ n = \frac{1}{1 + \frac{\gamma_0}{h \cos(\omega t)}} (n_1 + n_2) + n_3 + n_0, \]

\[ n_0 \text{ – coefficient belonging to the dynamic absorber; } \]
\[ n_1 \text{ – to lift wing; } n_2 \text{ – to stabilizator; } n_3 \text{ – to vertical fin.} \]

Therefore, the problem with attached dynamic absorber reduces itself to the right part \( F \left( y^0, t \right) \) of initial equation (2).

In such a case calculation chart takes the following form [2] presented in Fig.1. In given Fig.1 the frame of axis \( y^0 \omega^o \) is related to the dynamic absorber.

Equation (2) can be presented in the form:

\[ \frac{d^2 \gamma(t)}{dt^2} + n \frac{d\gamma(t)}{dt} + \gamma(t) + n \eta \gamma^m(t) = F \left( y^0, t \right), \] (4)

where \( \varepsilon \) and \( \eta \) are asymptotic parameters.

Note, that for particular case, when \( m = 3 \), differential equation (4) corresponds to Matieu – equation. Here it will be discussed general case for the parameter nonlinearity \( m \).

Using hybrid approach on the basis of perturbation technique and two - terms approximation of phase-integral method [4], an approximate analytical solution of equation problem (4) is:

\[ \gamma(t) = -\frac{1}{B_1^0(t)} \left\{ \sin K(t) \left[ c_1 + \gamma_1(t) + \eta \gamma_1(t) \right] + \cos K(t) \left[ c_2 + \gamma_2(t) + \eta \gamma_2(t) \right] \right\}, \] (5)

where first term in (5) corresponds to linear homogeneous solution, second term – to influence of right side of equation (4), third term – to non linearity influence.

Solution (5) can be rewrite as

\[ \gamma(t) = \exp \left[ -\frac{\nu(t)}{2} \right] \sin K(t) s_1 + \]
\[ + \varepsilon \int \frac{F(y_0(t), t) + \eta \gamma_0(t)}{B_1^0(t)0.25} \cos K(t) \, dt + \]
\[ \cos K(t)s_2 - \varepsilon \int \frac{F(y_0(t), t) + \eta \gamma_0(t)}{B_1^0(t)0.25} \sin K(t) \, dt, \] (6)

where non dimensional parameters and solution functions are:

\[ \gamma_0^0(t) = \frac{\exp \left[ -\frac{\nu(t)}{2} \right]}{B_1^0(t)} \left( c_1 \sin K(t) + c_2 \cos K(t) \right), \] (7)

\[ t = \frac{2 \tau}{\omega}, \quad \mu = \frac{av_0}{h} = ka, \quad \varepsilon^2 = \frac{1}{a}, \quad \eta = \frac{4c_2}{I_s \omega^2}, \quad n = \frac{2n}{I_s \omega^2}, \]

\[ \eta = \frac{4c_2}{I_s \omega^2}, \quad N(t) = [\gamma_0(t)]^m, \] (8)

\[ \gamma_1(t) = \frac{\exp \left[ -\frac{\nu(t)}{2} \right] \sin K(t)}{B_1^0(t)}, \] (9)

\[ \gamma_2(t) = \frac{\exp \left[ -\frac{\nu(t)}{2} \right] \cos K(t)}{B_1^0(t)0.25}, \] (10)

\[ W(t) = \frac{\exp \left[ -\frac{\nu(t)}{2} \right] K(t)}{B_1^0(t)0.5}, \] (11)

\[ \gamma_1(t) = 0, \quad \gamma_2(t) = 0, \quad W(t) = 0. \]

\[ \gamma_1(t) = \varepsilon \int \frac{F(y_0, t) \exp \left[ -\frac{\nu(t)}{2} \right] \cos K(t)}{B_1^0(t)0.5} \, dt, \] (12)

\[ \gamma_2(t) = -\varepsilon \int \frac{F(y_0, t) \exp \left[ -\frac{\nu(t)}{2} \right] \sin K(t)}{B_1^0(t)0.5} \, dt, \] (13)

\[ B_1(t) = 1 - \frac{2 \mu}{a} \cos 2\tau - \frac{\nu(t)^2}{4a} + \frac{\nu(t)}{2a}, \] (14)

\[ K(t) = \varepsilon^{-1} B_1^0(t) \, dt, \]

\[ c_{11}^0 = \left( \frac{1}{\gamma_0 + \cos \omega \tau} \right) + \left( 1 + \frac{\gamma_0}{h \cos \omega \tau} \right) (C_1 + C_2). \] (15)
where $c_1$, $c_2$ – have to be obtained from [1]. $c_1$, $c_2$ – are constants, determined from the given initial conditions.

For the given parameters of SC and initial conditions

$$\gamma(0) = \gamma_0, \quad \gamma'(0) = 0, \quad \gamma''(0) = 0,$$

expression (5) is an approximate analytical solution problem as function from the amplitude of periodic in time damping coefficient $n$ and parameter $\frac{\gamma_0}{h}$.

3. 3. INFLUENCE OF DEPENDING ON TIME PARAMETERS ON FREE VIBRATIONS OF SYSTEM

It is necessary to note, that for homogeneous problem, when $F(\gamma^0, t) = 0$, linear initial equation becomes

$$\varepsilon^2 \gamma''(t) + [a^*(\tau) - 2\mu \cos 2\tau] \gamma(t) = 0,$$

where $a^*(\tau) = a - \frac{v^2(\tau) - v'(\tau)}{\tau^2}$. and basic zone of SC system instability is function on dependent from time damping coefficient and vertical axis of Aines – Strett diagram removes in the left side [1].

For the given parameters SC system $v(\tau) = v_0(1 + 0.1\tau)$, $a = 100$, $\varepsilon = 0.1$, $v_0 = 1$, $\frac{\mu}{a} = 0.1$ and initial conditions (17) an analytical solution of equation (18) in one – term WKB approximation is:

$$\gamma(\tau) = \exp\left(-\frac{(1+0.1\tau)}{2}\right)\left[0.0092 \sin(8.94\tau + 0.747\tau^3) + 1.6487 \cos(8.94\tau + 0.747\tau^3)\right].$$

Results of numerical calculations are given in Fig.2.

4. CONCLUSIONS

Approximate analytical solutions for nonlinear dynamics of vehicle offers near-by the disturbed surface in the case when dimensionless amplitude of parametric excitation $\mu$ is being function of time is suggested. Proposed hybrid asymptotic approach can be efficient for further investigations of dynamic stability of structure near the wavy surface. The special attention in further researches must be directionally on the large values of parameter $\mu$. For this problem can be effective hybrid (WKB-G) asymptotic approach with the use of Galerkin’s orthogonality principle.
