Abstract: Globally, plant viral infection is one of the most difficult challenges of food security, where considerable losses in crop production occur. Nanoparticles are an effective control agent against numerous plant pathogens. However, there is limited knowledge concerning their effects against viral infection. In the present study, the green synthesis of zinc oxide nanoparticles (ZnO NPs) using aqueous leaf extract of Mentha spicata was achieved. X-ray diffraction patterns confirmed the crystalline nature of the prepared ZnO NPs. Dynamic light scattering and scanning electron microscopy analyses revealed that the resultant ZnO NPs were spherical in shape with a particle size ranged from 11 to 88 nm. Fourier transmission infrared spectroscopy detected different functional groups, capping and stability agents, and showed Zn-O bond within wavenumber of 487 cm$^{-1}$. Under greenhouse conditions, the antiviral activity of biological synthesized ZnO NPs (100 µg/mL) against Tobacco mosaic virus (TMV) was evaluated. The double foliar application of the prepared ZnO NPs, 24 h before and 24 h after TMV-inoculation, was the most effective treatment that showed a 90.21% reduction of viral accumulation level and disease severity. Additionally, the transcriptional levels of PAL, PR-1 (salicylic acid marker gene), CHS, and POD genes were induced and up-regulated in all ZnO NPs treated plants. Notably, the results exhibited that aqueous extract of Mentha spicata was an effective reducing agent for the green synthesis of ZnO NPs, which showed significant antiviral activity. Finally, the detected protective and curative activity of ZnO NPs against TMV can encourage us to recommend its application for plant viral disease management. To our knowledge, this is the first study describing the antiviral activity of the green synthesized ZnO NPs.

1. Introduction

Plant viruses are one of the most harmful diseases that result in significant losses in crop production worldwide [1]. Among them, tobacco mosaic virus (TMV) is the most serious plant virus, responsible for tremendous losses in crop yield quality and production [2–4]. Therefore, in order to maintain sustainable agriculture and food security, plant viral diseases must be controlled. Unfortunately, synthetic chemical treatments, including pesticides, are the widespread methods used for controlling plant diseases [5]. Such methods have negative impacts on the environment and human health. Hence, the development of alternative and effective ways to suppress plant viral infection is urgently needed.

Nowadays, nanotechnology is an active field of biological sciences research [6]. It is well documented that nanoparticles (NPs) play important roles in medical applications and have successful...
impacts on human pathogen control [7]. Traditionally, NPs have been synthesized via different physical and chemical methods, such as microwave irradiation, ultrasonication, laser vaporization, solid-state thermal decomposition, hydrothermal, and Sol-gel [8–11]. Such methods require high energy, expensive equipment, and space. In addition, the absorption of some toxic chemicals on their surface making it toxic for the environment and unsuitable for biological applications [12–14]. The green biosynthesis method of NPs is a safe alternative, low cost, and eco-friendly when compared to the conventional methods [15,16]. Additionally, the use of nontoxic extracts as reducing and stabilizing agents is also an additive advantage [17]. Because of its contents (many bioactive molecules such as polyphenols, enzymes, polysaccharides, esters, and terpenoids), plant leaf extracts may act as reducing and stabilizing agents in the nanoparticles synthesis processes [18–21].

*Mentha spicata* L. (genus *Mentha*, family Labiatae), commonly known as spearmint, garden mint, or common mint, is frequently used as herbal tea and is considered as one of the important additive spice for many foods all over the world [22]. It is well documented that the leaves of *M. spicata* are still used in traditional medicine to treat gastrointestinal disorders, where its essential oils possess antimicrobial and antioxidant properties [23–25]. The major chemical constituents of mentha plants were reported as pulegone, menthone, menthol, borneol, and piperitone [26,27]. Phytochemical studies showed that phenolic, flavonoid, steroids, and terpenoid were the major components of the leaves extracts responsible for the reduction and stabilization of NPs [25,28].

Recently, NPs, in a nanoscale range (1 nm to 100 nm), has been integrated into plant protection, as a substitution for chemical pesticides, and disease management [29,30]. At a suitable dose, NPs have the potential to promote plant growth and inhibit pathogen infection [31]. However, their antiviral properties are still in its infancy and the corresponding mechanisms are largely unclear [32]. Many researchers reported that silver nanoparticles (Ag NPs) exhibited antiviral activities against sunhemp rosette virus (SHRV) [33], bean yellow mosaic virus (BYMV) [34], tomato mosaic virus (ToMV) and potato virus Y (PVY) [35]. They suggested that Ag NPs could bind to the virus particles and inhibit viral nucleic acid replication in the plant cell. Moreover, induction of systemic acquired resistance (SAR) and improvement releasing of reactive oxygen species (ROS), which are associate with the increase in antioxidant activity, was observed [36,37].

Many studies showed that metal oxide NPs improved plant fertilization processes, increased plant growth parameters, yield, and quality, apart from their antimicrobial properties. Among metal oxide nanoparticles, zinc oxide nanoparticles (ZnO NPs) is a bio-safe material having a wide range of applications in medical, industrial, agricultural, and environmental fields [38,39]. In agriculture, utilization of ZnO NPs increased plant resistance to a broad spectrum of microbes, reduced disease severity, and enhanced crop production [37,38]. Additionally, research investigations dealing with the potential activity of ZnO NPs against plant viral disease are very limited and still under investigation. Recently, the antiviral activity of chemically synthesized ZnO NPs against TMV and PVY in the tobacco plant was reported [32]. In the present study, we aimed to green synthesize ZnO NPs using *M. spicata* extract. Moreover, the biologically synthesized ZnO NPs were investigated using X-ray diffraction (XRD), dynamic light scattering (DLS), scanning electron microscopy (SEM), fourier transform-infrared (FTIR) spectroscopy. Additionally, the antiviral activity and efficiency of the biosynthesized ZnO NPs in inducing SAR against TMV and its effects on plant growth parameters and the transcriptional levels of tomato-defense genes, (phenylalanine ammonia-lyase (PAL), pathogen-related protein 1 (PR-1), chalcone synthase (CHS), and peroxidase (POD), were studied. To our knowledge, this is the first report of the antiviral activity of biologically synthesized ZnO NPs against plant viral infection.
2. Materials and Methods

2.1. Plant Materials and Source of Viral Isolate

*Mentha spicata* L. leaves were collected from a farm in New Borg El-Arab city, Alexandria Governorate, Egypt. Virus-free tomato seeds (*Solanum lycopersicum* L.) cultivar GS 12 was obtained from the Agriculture Research Center, Ministry of Agriculture, Egypt. The TMV strain KH1 (Acc# MG264131) used in this study was previously isolated from infected tomato plants [40], and maintained continuously on *Nicotiana tabacum* plants under greenhouse conditions.

2.2. Leaves Extract Preparation and Green Synthesis of Zinc Oxide Nanoparticles

Fresh leaves of *M. spicata* were washed thoroughly with running tap water, to remove debris and other contaminations, washed with ultrapure Milli-Q water three times, and air-dried at room temperature. The dried leaves were pulverized and powdered by a sterile electric blender. The aqueous extract was prepared by adding 10 g of leaf powder to 100 mL of sterile distilled water and magnetically stirred for 2 h at 60 °C. The extract mixture was left to cool down at room temperature, filtered through sterile Whatman No. 1 filter paper, and finally stored at 4 °C until further analysis. A 0.2 M aqueous solution of zinc acetate dihydrate (purity 99%, Sigma Aldrich, Darmstadt, Germany) was prepared by dissolving 4.39 g of zinc acetate in 100 mL distilled water. Green synthesis of zinc oxide nanoparticles (ZnO NPs) was carried out by the addition of 30 mL of aqueous leaf extract of *M. spicata* to 70 mL of the freshly prepared zinc acetate solution. The reacted solution was mixed, stirred, and pH was adjusted to 12 by adding 3 M sodium hydroxide resulting in a pale white aqueous suspension. After stirring for 2 h, the pale-white ZnO NPs were precipitated and washed three times with sterile distilled water followed by ethanol wash to get rid of the impurities. A pale-white powder of ZnO NPs was obtained after drying the precipitate at 60 °C overnight.

2.3. Characterization of Zinc Oxide Nanoparticles

The physical properties and morphological structures of the prepared ZnO NPs were investigated using different techniques. X-ray diffraction (XRD) analysis was carried out using XRD-7000 (Shimadzu, Kyoto, Japan) diffractometer with Cu Kα radiation beam (λ = 0.154060 nm), operated at 30 KV and 30 mA and collected data were between 10° and 80° in 2θ. Fourier transform infrared (FTIR) spectroscopy (FTIR–8400 S, Shimadzu, Tokyo, Japan) analysis was performed to investigate different functional groups of the prepared extract. The morphological structures and size of ZnO NPs were characterized by scanning electron microscopy (SEM) at 20 kV (JSM-6360 LA, JEOL, Tokyo, Japan). The particle size distribution of biosynthesized ZnO NPs was determined by dynamic light scattering (DLS) with a Zetasizer Nano Z 590 (Malvern, Granta Lodge, UK) instrument at 25 °C.

2.4. Greenhouse Experimental Design and Antiviral Activity Assay

The ZnO NPs were suspended in sterile distilled water at 10 mg/mL, and then diluted with sterile distilled H₂O to obtain a final concentration of 100 µg/mL. By using the half-leaf method [41,42], the antiviral activity of ZnO NPs was primary tested on *Datura stramonium*, as a local lesion host for TMV, according to the inhibition percentage towards the number of local lesions. Under insect-proof greenhouse conditions, tomato seeds were surface sterilized and cultivated in plastic pots (20 cm in diameter) filled with sterilized soil (clay: sand, 1:1). At 28th days post seedlings, tomato seedlings were transplanted into new pots, and one week later, two upper true leaves of each tomato plant were dusted with carborundum and mechanically inoculated with 1 mL of semi-purified TMV as previously described [43,44]. The experiment was carried out in five treatments, each treatment was comprised of five replicates, and each pot contained three tomato plants. The first treatment (T1) was mock-treated plants (control), in which tomato plants inoculated with viral inoculation buffer + foliar spraying of sterile distilled H₂O. The second treatment (T2) was plants inoculated with TMV (infected). The third treatment (T3) included plants treated by foliar spraying of ZnO NPs 24 h before inoculation of TMV.
The fourth treatment (T4) was plants treated by foliar spraying of ZnO NPs 24 h after the inoculation of TMV. The fifth treatment (T5) included tomato plants treated by twice foliar spraying of ZnO NPs, 24 h before inoculation of TMV and 24 h post-inoculation. All plants were kept under greenhouse conditions, 28 °C/16 °C (day/night) and 70% relative humidity, and daily observed for the recording of symptom development. Five independent biological replicates of tomato leaves of all treatments were collected at 21 dpi and subjected to RNA extraction.

2.5. RNA Extraction and qRT-PCR Assay

Total plant RNA was extracted using RNeasy Mini Kit according to the manufacturer’s instructions (QIAGEN, Hilden, Germany). The purity and concentration of the extracted RNA were determined using SPECTROstar Nano (BMG Labtech, Ortenberg, Germany), while the agarose gel electrophoresis technique was used to check the integrity of RNA. One µg of RNA was used to synthesize the first strand of cDNA as performed and described previously [45]. The TMV accumulation level and transcriptional changes of four tomato defense-related genes (Table 1) were investigated using the qRT-PCR technique as previously performed [46,47]. To normalize the transcript expression levels, β-actin (Table 1) was used as a reference gene [48]. Each biological treatment was performed with three technical replicates on a Rotor-Gene 6000 (QIAGEN, Germantown, AL, USA) using SYBR Green PCR Master Mix (Thermo, Applied Biosystems, Foster, CA, USA). Each reaction was comprised a 20 µL containing 1 µL of 10 pmol/µL of each primer, 10 µL of 2 × SYBR Green PCR Master Mix, 1 µL of cDNA template, and 7 µL of nuclease-free water. The relative expression level was accurately calculated according to Livak and Schmittgen [49].

Table 1. Nucleotide sequences of qRT-PCR primers used in this study.

| Primer Name                        | Abbreviation | Direction    | Sequence (5′–3′)                  |
|-----------------------------------|--------------|--------------|-----------------------------------|
| Phenylalanine Ammonia-Lyase       | PAL          | Forward      | ACGGGTTGCCCATCTAATCTGACA          |
|                                   |              | Reverse      | CGACAGAAATAAGAAGCCCATCGCAAT       |
| Pathogenesis Related Protein-1    | PR-1         | Forward      | CCAAGACTATCTTGCAGGTTC             |
|                                   |              | Reverse      | GAACCTAACGACAGCAGATACCA           |
| Chalcone Synthase                 | CHS          | Forward      | CACCGTGGAGGAGTATCAGGAGGC          |
|                                   |              | Reverse      | TGATCAACACGAGTGCAGACGGGG          |
| Peroxidase                        | POD          | Forward      | TGGAGGTCCAACATGCGCAAGTTCT         |
|                                   |              | Reverse      | TGCCACATCTTGGCCCTTCCAAATG         |
| Tobacco mosaic virus-Coat Protein  | TMV-CP       | Forward      | ACGACTGCCGAAACGTTAGA             |
|                                   |              | Reverse      | CAAGTTGCGGACGACGAGGT             |
| Beta-Actin                        | β-actin      | Forward      | ATGCCATCTCCCTTTGCAGGTA            |
|                                   |              | Reverse      | GAGTTGTATGTTAGTTCGTCGTGGATT       |

2.6. Statistical Analyses

The relative expression values of the three replicates for each biological treatment were analyzed by one-way ANOVA in the CoStat software package. Significant differences among relative expression levels were determined according to the least significant differences (LSD) at the $p \leq 0.05$ level of probability, and standard deviations ($±$SD) were shown as column bars. Compared to mock-inoculated tomato tissues, relative expression values greater than 1 were categorized as increases in gene expression (up-regulation), while values less than 1 were considered as decreases in expression levels (down-regulation).
3. Results and Discussion

3.1. X-ray Diffraction (XRD) Analysis

The XRD pattern of the biosynthesized ZnO NPs using leaves extract of *M. spicata* was shown in Figure 1. The 2θ values of XRD at 31.76°, 34.44°, 36.24°, 47.56°, 56.66°, 62.90°, 66.42°, 67.96°, 69.14°, 72.64°, and 76.98° were assigned to (100), (002), (101), (102), (110), (103), (200), (112), (201), (004), and (202) planes, respectively. All the diffraction peaks were indexed in the ZnO wurtzite structure (JCPDS card number 01-089-1397) and agree with XRD peaks of biosynthesized ZnO NPs by *M. spicata* plant extract [25]. The sharp and narrow peaks indicated that the biosynthesized ZnO NPs were highly crystallized. Additionally, ZnO NPs were free of impurities where no characteristic XRD peaks other than zinc oxide peaks were observed [50,51].

![Figure 1. X-ray diffraction (XRD) patterns of zinc oxide nanoparticles biosynthesized by Mentha spicata leaf extract as reducing agents.](image)

3.2. FTIR Analysis

FTIR spectroscopy was used to identify the functional groups that exist in the *M. spicata* extract that may act as reducing agents in the process of ZnO NPs biosynthesis. In the current study, it was found that the secondary metabolites of *M. spicata* were responsible for the reduction of zinc acetate dihydrate into ZnO NPs. The FTIR spectrum of biosynthesized ZnO NPs exhibited several peaks at 3942, 3898, 3858, 3744, 3245, 2362, 2158, 2107, 2048, 1636, 1559, 1514, 1395, 1087, 1033, 932, 840, 774, 714, 487, and 412 cm⁻¹ (Figure 2). The broad peak at 3245 cm⁻¹ indicated the presence of hydrogen-bonded groups and could be corresponded to hydroxyl groups (O-H) stretching out from the phenolic compounds that were existed in the plant extract [52–54]; likewise, the peaks at 3942–3744 cm⁻¹ representing stretching vibration of O-H group [55,56]. The band at 2362 corresponded to N-H bond of the primary and secondary amides. The peaks at 1636, 1559, 1514, and 1395 cm⁻¹ have been assigned to C=C stretch of alkenes or C=O stretch of amides [52,53]. The bands at 1087 and 1033 are attributed to stretching vibrations of the C-O bond from biomolecules that existed in the leaf extract [54,56]. Additionally, peaks at 932, 840, 774 and 714 could correspond to C-N stretching amine groups [57]. The major absorption band at 487 cm⁻¹ was allotted and characteristic to the Zn-O bond [25,52,56,58].
3.3. Particle Size Distribution and Scanning Electron Microscopy Analysis

Dynamic light scattering (DLS) is a widely used method for determining particle size distribution in a colloidal solution. In the present study, DLS analysis revealed that the average particle size of the prepared ZnO NPs in the aqueous medium was 74.68 nm (Figure 3). The surface morphology of the biosynthesized ZnO NPs was examined using scanning electron microscopy (SEM) analysis. SEM images showed that most of ZnO NPs were spherical, with some agglomerated in shape and the particle diameter range was between 11 and 80 nm (Figure 4). SEM analysis confirmed the morphology and size of the prepared ZnO NPs [59].
3.4. Effect of Zn NPs on Disease Severity and TMV Systemic Accumulation Level

To investigate the anti-TMV activity of the biologically prepared ZnO NPs, protective and curative assays were checked on D. stramonium plants by counting local lesions that were developed on the inoculated leaves. As shown in Figure 5, the number of local lesions that appeared on the right side of the treated leaves with ZnO NPs (100 µg/mL) were significantly lower than the number of lesions on the untreated left side of the leaves. The results of the protective (upper right halves of the leaves were treated with ZnO NPs, 24 h before TMV inoculation) and curative (upper right halves of the leaves were treated with ZnO NPs, 24 h after TMV inoculation) assays revealed that the biologically synthesized ZnO NPs show both protective and curative activities against TMV, with better protective activity (Figure 5).

Under greenhouse conditions, the foliar application of the biologically synthesized ZnO NPs (100 µg/mL) significantly decreased disease severity, increased plant growth, and reduced viral accumulation levels in the treated tomato plants, when compared to the infected tomato plants without treatments (T2). In the current study, at 14 dpi, the TMV-infected tomato plants (T2) showed severe mosaic symptoms similar to those reported previously [60]. On the other hand, a delayed in the development of infection symptoms for three, four, and five days was observed in ZnO NPs treated plants before viral inoculation (T3), ZnO NPs treated plants after viral inoculation (T5), and ZnO NPs treated plants before and after viral inoculation (T5), respectively (Figure 6). No symptoms were observed on the mock-treated plants (T1). Additionally, ZnO NPs-treated tomato plants showed a significant decrease in TMV accumulation levels in plant tissues. The qRT-PCR results exhibited that the higher accumulation level of TMV (136.60-fold) was in T2 plants, while significant decreases of accumulation level in T3 (37.14-fold), T4 (63.55-fold), and T5 (13.36-fold) plants were observed (Figure 5). The considerable reduction in TMV accumulation level in tomato leaves by 72.81%, 53.47%, and 90.21% in T3, T4, and T5 treatments, respectively, reflected the anti-TMV activity of the biologically prepared ZnO NPs. In this context, Cai et al. [32] reported that the foliar application of the chemically prepared ZnO NPs decreased the accumulation level of TMV in tobacco plants and reduced disease severity [32]. Moreover, the treatment of tomato plants with Ag NPs reduced the disease severity and ToMV or PVY concentration levels inside plant tissues [35].

(A) mock-treated plants (T1), (B) plants inoculated with TMV only (T2), (C) plants treated with ZnO NPs (100 µg/mL) 24 h before inoculation of TMV (T3), (D) plants treated with ZnO NPs (100 µg/mL) 24 h after inoculation of TMV (T4), (E) plant treated with ZnO NPs (100 µg/mL) 24 h before inoculation of TMV and 24 h after inoculation with TMV (T5).

3.5. Transcriptional Levels of Defense-Related Genes

At 21 dpi of all treatments, the transcription levels of four tomato-innate defense genes (PAL, PR-1, CHS, and POD) were investigated. Beside it is the first enzyme in the phenylpropanoid pathway linking the primary and secondary metabolism [61], PAL is involved in salicylic acid (SA) biosynthesis [62]. SA is an important signal that regulates systemic acquired resistance (SAR) in plants [42,63] and its
role in plant immunity has been investigated for decades. The activation of SA, in response to pathogens, results in the accumulation and overexpression of PR-1 (SA marker gene) [64]. Compared to mock-inoculated plants (control (T1)) in the current study, a significant up-regulation of PAL with relative expression levels of 2.448-, 1.753-, and 2.590-fold change higher than control were observed in T3, T4, and T5, respectively (Figure 7). Like PAL, PR-1 expression levels in all treatments were increased with relative transcriptional levels of 1.531-, 1.375-, and 1.802-fold change in T3, T4, and T5, respectively, compared to control (Figure 7). On the contrary, PAL and PR-1 of T2 plants showed a significant down-regulation with relative expression levels of 0.064- and 0.272-fold change lower than the control treatment, respectively (Figure 7). Consequently, foliar spraying of tomato plants with the biologically synthesized ZnO NPs, either as a single treatment (before or after inoculation with TMV) or as a double treatment (before + after inoculation with TMV) triggered the expression of PAL and PR-1 genes that may cause elevated SA accumulation levels. These results suggested that the biologically synthesized ZnO NPs via M. spicata may mediate the activation of the induced systemic resistance (ISR) and can play a major role in tomato SAR against TMV infection. Many researchers reported that increased resistance against virulent pathogens was associated with an increased in PAL and PR-1 expression and elevated endogenous SA accumulation levels inside plant tissues [65–69].

The obtained results are in agreement with Cai et al. [32] who reported that upon TMV infection, chemically prepared ZnO NPs increased the expression level of the tobacco PR-1 gene that resulted in the initiation of the SA signaling pathway. In the current study, the detected down-regulation of PR-1 and PAL genes in T2 plants could be attributed to the suppressing activities of TMV against the tomato immune defense system, which resulted in a failure in the development of SAR activity.

Flavonoids, secondary metabolites, compounds play important roles in plant resistance against pathogenic microorganisms, including viruses [69–71]. Once infection occurs, flavonoids transport to the infection sites, induce hypersensitivity reactions and activate programmed cell death [72,73]. Chalcone synthase, CHS, encodes the first enzyme of flavonoid pathway that synthesizes naringenin chalcones, is strictly needed in various plant tissues for flavonoid production [74,75]. Compared to control (T1), the transcriptional levels of CHS in treatments of T2, T3, T4, and T5 were up-regulated with relative expression levels of 1.273-, 2.38-, 1.848-, and 3.556-fold increase, respectively (Figure 7). These results showed that TMV infection slightly induced the expression of CHS in tomato tissues, while ZnO NPs treatments (T3, T4, and T5) exhibited more accumulation of CHS inside the tomato tissues. In line with the obtained results, foliar application of the biologically synthesized ZnO NPs may increase flavonoid production in plant tissues that resulted in the stimulation of the defense system against viral infection.

Reactive oxygen species (ROS) promotes programmed cell death at plant cell infection sites and plays an important role as a signaling molecule for the activation of antioxidant activity and the induction of the genes coding for pathogenesis-related proteins (PRs) [76–79]. It was reported that the increased activity of peroxidase (POD), alternative producers of ROS, was correlated with the increasing plant defense against pathogens [78,80]. In the current study, we observed that the application of the biologically synthesized ZnO NPs significantly increased the transcriptional levels of POD by 2.641-, 2.175-, and 3.177-fold change higher than control in T3, T4, and T5, respectively (Figure 7). Conversely, the POD of T2 plants was down-regulated with a relative expression level of 0.672-fold change lower than control (Figure 7). It was observed that the induction of POD resulted in an increase of chlorophyll content and enhanced plant resistance against mungbean yellow mosaic virus and TMV [81,82]. In addition, foliar application of Ag NPs exhibited an improvement in releasing ROS and increasing antioxidant enzymes in virally infected plant tissues [36,37]. Moreover, MgO NPs, ZnO NPs, and SiO2 NPs treatments induced ROS generation and suppressed TMV infection in tomato and tobacco plants [32,83]. Therefore, the foliar applications of the biosynthesized ZnO NPs may enhance SAR by releasing ROS and stimulating the expression of PR genes and SA accumulation [32].
Figure 7. A histogram showing the relative expression level of PAL, PR-1, CHS, and POD in TMV-infected tomato plants at 21 days post inoculation. T1 = Mock-treated plants (Control), T2 = plants inoculated with TMV only, T3 = plants treated with ZnO NPs (100 µg/mL) 24 h before inoculation of TMV, T4 = plants treated with ZnO NPs (100 µg/mL) 24 h after inoculation of TMV, T5 = plant treated with ZnO NPs (100 µg/mL) 24 h before inoculation of TMV and 24 h after inoculation with TMV. Columns represent mean value from three biological replicates and bars indicate standard deviation (±SD). Significant differences between samples were determined by one-way ANOVA using CoStat software. Means were separated by least significant difference (LSD) test at $p \leq 0.05$ levels and indicated by small letters. Columns with the same letter means do not differ significantly.

4. Conclusions

The present investigation reported a simple, eco-friendly method for the green biosynthesis of ZnO NPs via aqueous extract of Mentha spicata leaf as a reducing and capping agent. XRD analysis confirmed the formations of ZnO NPs crystalline phases, while DLS and SEM analyses showed that ZnO NPs have a spherical shape and an average particle size of 74.68 nm. Greenhouse experimental results showed that the foliar treatment of tomato plants using biologically synthesized ZnO NPs (100 µg/mL) induced systemic acquired resistance (SAR), decreased disease severity, reduced TMV accumulation level, increased growth parameters, and up-regulated the transcriptional levels of PAL, PR-1, CHS, and POD genes. In line with the obtained data, we suggest that the biologically prepared ZnO NPs have potent antiviral activity and can be applied in plant protection as elicitor molecules for the induction of SAR and plant viral disease management.
Author Contributions: Conceptualization, A.A. and A.A.A.-A.; methodology, A.A.; software, A.A.; formal analysis, A.A.; investigation, A.A.A.-A.; writing—original draft preparation, A.A.; writing—review and editing, A.A.A.-A. All authors have read and agreed to the published version of the manuscript.

Funding: The authors extend their appreciation to the Deanship of Scientific Research at King Saud University for funding the work through the research group project No (RGP-1440-094).

Acknowledgments: The authors thank Ahmed Kenawy (GEBRI, City of Scientific Research and Technological Applications, Alexandria, Egypt) for the critical reading and revision of the manuscript.

Conflicts of Interest: The authors declare no competing interest.
