GRADIENT ESTIMATE AND HARNACK INEQUALITY ON
NON-COMPACT RIEMANNIAN MANIFOLDS

MARC ARNAUDON, ANTON THALMAIER, AND FENG-YU WANG∗

ABSTRACT. A new type of gradient estimate is established for diffusion semigroups on non-compact complete Riemannian manifolds. As applications, a global Harnack inequality with power and a heat kernel estimate are derived for diffusion semigroups on arbitrary complete Riemannian manifolds.

1. The main result

Let $M$ be a non-compact complete Riemannian manifold, and $P_t$ be the Dirichlet diffusion semigroup generated by $L = \Delta + \nabla V$ for some $C^2$ function $V$. We intend to establish reasonable gradient estimates and Harnack type inequalities for $P_t$. In case that $\text{Ric} - \text{Hess} V$ is bounded below, a dimension-free Harnack inequality was established in [15], which according to [17], is indeed equivalent to the corresponding curvature condition. See e.g. [2] for equivalent statements on heat kernel functional inequalities; see also [8, 3, 9] for a parabolic Harnack inequality using the dimension-curvature condition by shifting time, which goes back to the classical local parabolic Harnack inequality of Moser [10].

Recently, some sharp gradient estimates have been derived in [13, 19] for the Dirichlet semigroup on relatively compact domains. More precisely, for $V = 0$ and a relatively compact open $C^2$ domain $D$, the Dirichlet heat semigroup $P_D t$ satisfies

(1.1) \[ |\nabla P_D t f(x)| \leq C(x, t) P_D t f(x), \quad x \in D, \ t > 0, \]

for some locally bounded function $C: D \times [0, \infty[ \to ]0, \infty[$ and all $f \in \mathcal{B}_0^+$, the space of bounded non-negative measurable functions on $M$. Obviously, this implies the Harnack inequality

(1.2) \[ P_D t f(x) \leq \tilde{C}(x, y, t) P_D t f(y), \quad t > 0, \ x, y \in D, \ f \in \mathcal{B}_0^+, \]

for some function $\tilde{C}: M^2 \times [0, \infty[ \to ]0, \infty[$. The purpose of this paper is to establish inequalities analogous to (1.1) and (1.2) globally on the whole manifold $M$.

On the other hand however, both (1.1) and (1.2) are in general wrong for $P_t$ in place of $P_D t$. A simple counter-example is already the standard heat semigroup on $\mathbb{R}^d$. Hence, we turn to search for the following slightly weaker version of gradient inequalities:

1991 Mathematics Subject Classification. 58J65 58J35 60H30.

estimate:

\[
|\nabla P_t f(x)| \leq \delta (P_t f \log f - P_t f \log P_t f)(x) + \frac{C(\delta, x)}{t \wedge 1} P_t f(x),
\]

\[x \in M, \quad t > 0, \quad \delta > 0, \quad f \in \mathcal{B}_B^+,
\]

for some positive function \(C : [0, \infty[ \times M \rightarrow [0, \infty[\). This kind of gradient estimate is new and, in particular, implies the Harnack inequality with power introduced in [15] (see Theorem 1.2 below).

**Theorem 1.1.** There exists a continuous positive function \(F\) on \([0, 1] \times M\) such that

\[
|\nabla P_t f(x)| \leq \delta (P_t f \log f - P_t f \log P_t f)(x)
\]

\[+ \left( F(\delta \wedge 1, x) \left( \frac{1}{\delta(t \wedge 1)} + 1 \right) + \frac{2\delta}{\epsilon} \right) P_t f(x),
\]

\(\delta > 0, \quad x \in M, \quad t > 0, \quad f \in \mathcal{B}_B^+\).

**Theorem 1.2.** There exists a positive function \(C \in C([1, \infty[ \times M^2)\) such that

\[
(P_t f(x))^\alpha \leq (P_t f^\alpha(y)) \exp \left\{ \frac{2(\alpha - 1)}{\epsilon} + \alpha C(\alpha, x, y) \left( \frac{\alpha \rho^2(x, y)}{(\alpha - 1)(t \wedge 1)} + \rho(x, y) \right) \right\},
\]

\(\alpha > 1, \quad t > 0, \quad x, y \in M, \quad f \in \mathcal{B}_B^+\),

where \(\rho\) is the Riemannian distance on \(M\). Consequently, for any \(\delta > 2\) there exists a positive function \(C_\delta \in C([0, \infty[ \times M)\) such that the transition density \(p_t(x, y)\) of \(P_t\) with respect to \(\mu(dx) := e^{\psi(x)}dx\), where \(dx\) is the volume measure, satisfies

\[
p_t(x, y) \leq \exp \left\{ -\rho(x, y)^2/(2\delta t) + C_\delta(t, x) + C_\delta(t, y) \right\}, \quad x, y \in M, \quad t \in [0, 1[.
\]

**Remark 1.1.** According to the Varadhan asymptotic formula for short time behavior, one has \(\lim_{t \to 0} 4t \log p_t(x, y) = -\rho(x, y)^2, \quad x \neq y\). Hence, the above heat kernel upper bound is sharp for short time.

The paper is organized as follows: In Section 2 we provide a formula expressing \(P_t\) in terms of \(P_t^D\) and the joint distribution of \((\tau, X_\tau)\), where \(X_t\) is the \(L\)-diffusion process and \(\tau\) its hitting time to \(\partial D\). Some necessary lemmas and technical results are collected. Proposition 2.5 is a refinement of a result in [19] to make the coefficient of \(\rho(x, y)/t\) sharp and explicit. In Section 3 we use parallel coupling of diffusions together with Girsanov transformation to obtain a gradient estimate for Dirichlet heat semigroup. Finally, complete proofs of Theorems 1.1 and 1.2 are presented in Section 4.

To prove the indicated theorems, besides stochastic arguments, we make use of a local gradient estimate obtained in [13] for \(V = 0\). For the convenience of the reader, we include a brief proof for the case with drift in the Appendix.

2. Some Preparations

Let \(X_s(x)\) be an \(L\)-diffusion process with starting point \(x\) and explosion time \(\xi(x)\). For any open \(C^2\) domain \(D \subset M\) such that \(x \in D\), let \(\tau(x)\) be the first hitting time of \(X_s(x)\) at the boundary \(\partial D\). We have

\[
P_t f(x) = \mathbb{E} \left[ f(X_t(x)) 1_{\{t < \xi(x)\}} \right], \quad P_t^D f(x) = \mathbb{E} \left[ f(X_t(x)) 1_{\{t < \tau(x)\}} \right].
\]
Lemma 2.2. The following formula holds:

\[ P_t f(x) = P_t^D f(x) + \int_{[0,t] \times \partial D} P_{t-s} f(z) h_x(s,z) \, d\nu(dz) \]

Consequently, the density \( s \mapsto \ell_x(s) \) of \( \tau(x) \) satisfies the equation:

\[ \ell_x(s) = \int_D ( - \partial_t p_t^D(x,y)) \mu(dy). \]

**Proof.** Every bounded continuous function \( f : \partial D \to \mathbb{R} \) extends continuously to a function \( h \) on \( D \) which is harmonic in \( D \) and represented by

\[ h(x) = \int_{\partial D} K(z,x)f(z) \nu(dz). \]

Recall that \( z \mapsto K(z,x) \) is the density of \( X_{\tau(x)} \). Hence

\[ E[f(X_{\tau(x)})] = h(x) = \int_{\partial D} K(z,x)f(z) \nu(dz). \]

On the other hand, the identity

\[ h(x) = E[h(X_{t\wedge\tau(x)})] \]

yields

\[ h(x) = \int_D p_t^D(x,y)h(y) \mu(dy) + \int_{\partial D} \nu(dz) \int_0^t h_x(s,z) f(z) \, ds \]

\[ = \int_D p_t^D(x,y) \left( \int_{\partial D} K(z,y)f(z) \nu(dz) \right) \mu(dy) + \int_{\partial D} \nu(dz) \int_0^t h_x(s,z) f(z) \, ds \]

\[ = \int_{\partial D} f(z) \left( \int_D p_t^D(x,y)K(z,y) \mu(dy) + \int_0^t h_x(s,z) \, ds \right) \nu(dz), \]

which implies that

\[ K(z,x) = \int_D p_t^D(x,y)K(z,y) \mu(dy) + \int_0^t h_x(s,z) \, ds. \]

Differentiating with respect to \( t \) gives

\[ h_x(t,z) = -\partial_t \int_D p_t^D(x,y)K(z,y) \mu(dy). \]

Since \( \partial_t p_t^D(x,y) \) is bounded on \([\varepsilon, \varepsilon^{-1}] \times \bar{D} \times \bar{D} \) for any \( \varepsilon \in ]0,1[ \), Eq. (2.1) follows by the dominated convergence.

Finally, Eq. (2.2) is obtained by integrating (2.1) with respect to \( \nu(dz) \). \( \Box \)

**Lemma 2.1.** Let \( K(z,x) \) be the Poisson kernel in \( D \) with respect to \( \nu \). Then

\[ h_z(t,z) = \int_D ( - \partial_t p_t^D(x,y)) K(z,y) \mu(dy). \]

**Proof.** Every bounded continuous function \( f : \partial D \to \mathbb{R} \) extends continuously to a function \( h \) on \( D \) which is harmonic in \( D \) and represented by

\[ h(x) = \int_{\partial D} K(z,x)f(z) \nu(dz). \]

Recall that \( z \mapsto K(z,x) \) is the density of \( X_{\tau(x)} \). Hence

\[ E[f(X_{\tau(x)})] = h(x) = \int_{\partial D} K(z,x)f(z) \nu(dz). \]

On the other hand, the identity

\[ h(x) = E[h(X_{t\wedge\tau(x)})] \]

yields

\[ h(x) = \int_D p_t^D(x,y)h(y) \mu(dy) + \int_{\partial D} \nu(dz) \int_0^t h_x(s,z) f(z) \, ds \]

\[ = \int_D p_t^D(x,y) \left( \int_{\partial D} K(z,y)f(z) \nu(dz) \right) \mu(dy) + \int_{\partial D} \nu(dz) \int_0^t h_x(s,z) f(z) \, ds \]

\[ = \int_{\partial D} f(z) \left( \int_D p_t^D(x,y)K(z,y) \mu(dy) + \int_0^t h_x(s,z) \, ds \right) \nu(dz), \]

which implies that

\[ K(z,x) = \int_D p_t^D(x,y)K(z,y) \mu(dy) + \int_0^t h_x(s,z) \, ds. \]

Differentiating with respect to \( t \) gives

\[ h_x(t,z) = -\partial_t \int_D p_t^D(x,y)K(z,y) \mu(dy). \]

Since \( \partial_t p_t^D(x,y) \) is bounded on \([\varepsilon, \varepsilon^{-1}] \times \bar{D} \times \bar{D} \) for any \( \varepsilon \in ]0,1[ \), Eq. (2.1) follows by the dominated convergence.

Finally, Eq. (2.2) is obtained by integrating (2.1) with respect to \( \nu(dz) \). \( \Box \)
Proof. By the strong Markov property we have
\[
P_t f(x) = \mathbb{E} \left[ f(X_t(x))1_{\tau<\xi(x)} \right]
= \mathbb{E} \left[ f(X_t(x))1_{\{t<\tau(x)\}} \right] + \mathbb{E} \left[ f(X_t(x))1_{\{\tau(x)<t<\xi(x)\}} \right]
\]
so that
\[
P_t^D f(x) = P_t^D f(x) + \int_{[0,t] \times \partial D} P_{t-s} f(z) h_x(s, z) \, ds \, \nu(dz).
\]
Next, since
\[
\partial_u p_s^D(x, y) = L p_s^D(\cdot, y)(x) = L p_{s/2}^D p_{s/2}^D(\cdot, y)(x) = P_{s/2}^D(\partial_u p_{s/2}^D(\cdot, y)|_{u=s/2})(x),
\]
it follows from (2.1) that
\[
(2.6) \quad h_x(s, z) = P_{s/2}^D h_z(s/2, z)(x).
\]
This completes the proof. \qed

We remark that formula (2.6) can also be derived from the strong Markov property without invoking Eq. (2.1). Indeed, for any \( u < s \) and any measurable set \( A \subset \partial D \), the strong Markov property implies that
\[
\mathbb{P} \{ \tau(x) > s, X_{\tau(x)}(x) \in A \} = \mathbb{E} \left[ (1_{u<s}) \mathbb{P} \{ \tau(x) > s, X_{\tau(x)}(x) \in A | \mathcal{F}_u \} \right]
= \int_D p_u^D(x, y) \mathbb{P} \{ \tau(y) > s - u, X_{\tau(y)}(y) \in A \} \mu(dy),
\]
and thus,
\[
h_x(s, z) = P_u^D h_z(s-u, z)(x), \quad s > u > 0, \ x \in D, \ z \in \partial D.
\]

Lemma 2.3. Let \( D \) be a relatively compact open domain and \( \rho_{\partial D} \) be the Riemannian distance to the boundary \( \partial D \). Then there exists a constant \( C > 0 \) depending on \( D \) such that
\[
\mathbb{P} \{ \tau(x) \leq t \} \leq Ce^{-\rho_{\partial D}(x)/16t}, \quad x \in D, \ t > 0.
\]

Proof. For \( x \in D \), let \( R := \rho_{\partial D}(x) \) and \( \rho_x \) the Riemannian distance function to \( x \). Since \( D \) is relatively compact, there exists a constant \( c > 0 \) such that \( L \rho_x^2 \leq c \) holds on \( D \) outside the cut-locus of \( x \). Let \( \gamma_t := \rho_x(X_t(x)) \), \( t \geq 0 \). By Itô’s formula, according to Kendall [7], there exists a one-dimensional Brownian motion \( b_t \) such that
\[
d\gamma_t^2 \leq 2\sqrt{2}\gamma_t \, db_t + c \, dt, \quad t \leq \tau(x).
\]
Thus, for fixed \( t > 0 \) and \( \delta > 0 \),
\[
Z_s := \exp \left( \frac{\delta}{t} \gamma_s^2 - \frac{\delta}{2} c s - 4 \frac{\delta^2}{t^2} \int_0^s \gamma_u^2 \, du \right), \quad s \leq \tau(x)
\]
is a supermartingale. Therefore,
\[
\mathbb{P} \{ \tau(x) \leq t \} = \mathbb{P} \left\{ \max_{s \in [0, t]} \gamma_{s \wedge \tau(x)} \geq R \right\} \leq \mathbb{P} \left\{ \max_{s \in [0, t]} Z_{s \wedge \tau(x)} \geq e^{\delta R^2 / t - \delta c - 4\delta^2 R^2 / t} \right\}
\leq \exp \left( c\delta - \frac{1}{t} (\delta R^2 - 4\delta^2 R^2) \right).
\]
The proof is completed by taking \( \delta := 1/8 \). \qed
Lemma 2.4. On a measurable space $(E, \mathcal{F}, \hat{\mu})$ satisfying $\hat{\mu}(E) < \infty$, let $f \in L^1(\hat{\mu})$ be non-negative with $\hat{\mu}(f) > 0$. Then for every measurable function $\psi$ such that $\psi f \in L^1(\hat{\mu})$, there holds:

$$
\int_E \psi f \, d\hat{\mu} \leq \int_E f \log \frac{f}{\hat{\mu}(f)} \, d\hat{\mu} + \hat{\mu}(f) \log \int_E e^\psi \, d\hat{\mu}.
$$

(2.7)

Proof. This is a direct consequence of [12] Lemma 6.45. We give a proof for completeness. Multiplying $f$ by a positive constant, we can assume that $\hat{\mu}(f) = 1$. If $\int_E e^\psi \, d\hat{\mu} = \infty$, then (2.7) is clearly satisfied.

If $\int_E e^\psi \, d\hat{\mu} < \infty$, then since $\int_E e^\psi \, d\hat{\mu} \geq \int_{\{f > 0\}} e^\psi \, d\hat{\mu}$, we can assume that $f > 0$ everywhere. Now from the fact that $e^{\psi f} \in L^1(\hat{\mu})$, we can apply Jensen’s inequality to obtain

$$
\log \left( \int_E e^\psi \, d\hat{\mu} \right) = \log \left( \int_E e^{\psi f} \frac{f}{\hat{\mu}(f)} \, d\hat{\mu} \right) \geq \int_E \log \left( e^{\psi f} \frac{f}{\hat{\mu}(f)} \right) f \, d\hat{\mu}
$$

(note the right-hand-side belongs to $\mathbb{R} \cup \{-\infty\}$). To finish we remark that since $\psi f \in L^1(\hat{\mu})$,

$$
\int_E \log \left( e^{\psi f} \frac{f}{\hat{\mu}(f)} \right) f \, d\hat{\mu} = \int_E \psi f \, d\hat{\mu} - \int_E f \log f \, d\hat{\mu}.
$$

Finally, in order to obtain precise gradient estimate of the type (1.4), where the constant in front of $\rho(x, y)/t$ is explicit and sharp, we establish the following revision of [19] Theorem 2.1.

Proposition 2.5. Let $D$ be a relatively compact open $C^2$ domain in $M$ and $K$ a compact subset of $D$. For any $\varepsilon > 0$, there exists a constant $C(\varepsilon) > 0$ such that

$$
|\nabla \log p^D_{t} (\cdot, y)(x)| \leq \frac{C(\varepsilon) \log (1 + t^{-1})}{\sqrt{t}} + \frac{(1 + \varepsilon) \rho(x, y)}{2t},
$$

\hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} \hspace{1cm} t \in ]0, 1[, \ x \in K, \ y \in D.

(2.8)

In addition, if $D$ is convex, the above estimate holds for $\varepsilon = 0$ and some constant $C(0) > 0$.

Proof. Since $\delta := \min_K \rho_{\partial D} > 0$, it suffices to deal with the case where $0 < t \leq 1\wedge \delta$. To this end, we combine the argument in [19] with relevant results from [16, 18].

(a) Let $t_0 = t/2$ and $y \in D$ be fixed. Take

$$
f(x, s) = p^D_{t+s}(x, y), \ x \in D, \ s > 0.
$$

Applying Theorem 5.1 of the Appendix to the cube

$$
Q := B(x, \rho_{\partial D}(x)) \times [s - \rho_{\partial D}(x)^2/2, s] \subset D \times [-t_0, t_0], \ s \leq t_0,
$$

we obtain

$$
|\nabla \log f(x, s)| \leq \frac{c_0}{\rho_{\partial D}(x)} \left( 1 + \log \frac{A}{f(x, s)} \right), \ s \leq t_0,
$$

(2.9)

where $A := \sup_Q f$ and $c_0 > 0$ is a constant depending on the dimension and curvature on $D$. By [9] Theorem 5.2,

$$
A \leq c_1 f(x, s + \rho_{\partial D}(x)^2), \ s \in ]0, 1[, \ x \in D,
$$

(2.10)
holds for some constant $c_1 > 0$ depending on $D$ and $L$. Moreover, by the boundary Harnack inequality of [1] (which treats $Z = 0$ but generalizes easily to non-zero $C^1$ drift $Z$),

\begin{equation}
(2.11) \quad f(x, s + \rho_{0D}(x)^2) \leq c_2 f(x, s), \quad s \in [0, 1], \ x \in D,
\end{equation}

for some constant $c_2 > 0$ depending on $D$ and $L$. Combining (2.9), (2.10) and (2.11), there exists a constant $c > 0$ depending on $D$ and $L$ such that

\begin{equation}
(2.12) \quad |\nabla \log f(x, s)| \leq \frac{c}{\sqrt{s}}, \quad x \in D, \ s \in [0, t_0] \text{ with } \rho_{0D}(x)^2 \leq s.
\end{equation}

(b) Let

$$\Omega = \{(x, s): \ x \in D, \ s \in [0, t_0], \ \rho_{0D}(x)^2 \geq s\}$$

and $B = \sup_{\Omega} f$. Since $\partial_s f = Lf$, for any constant $b \geq 1$, we have

$$(L - \partial_s)(f \log \frac{bB}{f}) = -\frac{|\nabla f|^2}{f}.$$ 

Next, again by $\partial_s f = Lf$ and the Bochner-Weizenböck formula,

$$(L - \partial_s)\frac{|\nabla f|^2}{f} \geq -2k\frac{|\nabla f|^2}{f},$$

where $k \geq 0$ is such that $\text{Ric} - \nabla Z \geq -k$ on $D$. Then the function

$$h := \frac{s|\nabla f|^2}{(1 + 2ks)f} - f \log \frac{bB}{f}$$

satisfies

\begin{equation}
(2.13) \quad (L - \partial_s)h \geq 0 \quad \text{on } D \times [0, \infty[.
\end{equation}

Obviously $b(\cdot, 0) \leq 0$, and (2.12) yields $h(x, s) \leq 0$ for $s = \rho_{0D}(x)^2$ provided the constant $b$ is large enough. Then the maximum principle and inequality (2.13) imply $h \leq 0$ on $\Omega$. Thus,

\begin{equation}
(2.14) \quad |\nabla \log f(x, s)|^2 \leq (2k + s^{-1}) \log \frac{bB}{f}, \quad (x, s) \in \Omega.
\end{equation}

(c) If $D$ is convex, by [16] Theorem 2.1 with $\delta = \sqrt{t}$ and $t = 2t_0$, we obtain (note the generator therein is $\frac{1}{2}L$)

$$f(x, t_0) = p^{D}_{2t_0}(x, y) = p^{D}_{2t_0}(y, x) \geq c_1 \varphi(y) t_0^{-d/2}e^{-\rho(x, y)^2/8t_0}, \quad x \in K, \ y \in D$$

for some constant $c_1 > 0$, where $\varphi > 0$ is the first Dirichlet eigenfunction of $L$ on $D$. On the other hand, the intrinsic ultracontractivity for $P^D_t$ implies (see e.g. [11])

$$f(z, s) = p^{D}_{t_0}(z, y) \leq c_2 \varphi(y) t_0^{-(d+2)/2}, \quad z, y \in D, \ s \leq t_0,$$

for some constant $c_2 > 0$ depending on $D$, $K$, and $L$. Combining these estimates we obtain

$$\frac{B}{f(x, s)} \leq c_3 t_0^{-1}e^{\rho(x, y)^2/8t_0}, \quad x \in K, \ s \leq t_0,$$

for some constant $c_3 > 0$ depending on $D$, $K$ and $L$. Hence by (2.14) for $s = t_0$ we get the existence of a constant $C > 0$ such that

$$|\nabla \log p^{D}_{2t_0}(\cdot, y)|^2 \leq (t_0^{-1} + 2k) \left( C + \log t_0^{-1} + \frac{\rho(x, y)^2}{8t_0} \right)$$
for all \( y \in D, x \in K \) and \( t_0 \in ]0,1[ \) with \( t_0 \leq \rho_{\partial D}(x)^2 \). This completes the proof by noting that \( t = 2t_0 \).

(d) Finally, if \( D \) is not convex, then there exists a constant \( \sigma > 0 \) such that

\[
\langle \nabla N X, X \rangle \geq -\sigma |X|^2, \quad X \in T \partial D,
\]

where \( N \) is the outward unit normal vector field of \( \partial D \). Let \( f \in C^\infty(\mathcal{D}) \) such that \( f = 1 \) for \( \rho_{\partial D} \geq \varepsilon, 1 \leq f \leq e^{2\varepsilon\sigma} \) for \( \rho_{\partial D} \leq \varepsilon \), and \( N \log f)_{|\partial D} \geq \sigma \). By Lemma 2.1 in [18], \( \partial D \) is convex under the metric \( \tilde{g} := f^{-2}\langle \cdot, \cdot \rangle \). Let \( \tilde{\Delta}, \tilde{\nabla} \) and \( \tilde{\rho} \) be respectively the Laplacian, the gradient and the Riemannian distance induced by \( \tilde{g} \). By Lemma 2.2 in [18],

\[
L := \Delta + \nabla V = f^{-2} \left[ \tilde{\Delta} + (d-2)f\nabla f \right] + \nabla V.
\]

Since \( D \) is convex under \( \tilde{g} \), as explained in the first paragraph in Section 2 of [18],

\[
\tilde{g}(\tilde{\nabla}\tilde{\rho}(y, \cdot), \tilde{\nabla}\varphi)|_{\partial D} < 0,
\]

so that

\[
\tilde{\sigma}(y) := \sup_D \tilde{g}(\tilde{\nabla}\tilde{\rho}(y, \cdot), \tilde{\nabla}\varphi) < \infty, \quad y \in D.
\]

Hence, repeating the proof of Theorem 2.1 in [18], but using \( \tilde{\rho} \) and \( \tilde{\nabla} \) in place of \( \rho \) and \( \nabla \) respectively, and taking into account that \( f \to 1 \) uniformly as \( \varepsilon \to 0 \), we obtain

\[
p^D_{2t_0}(x, y) \geq C_1(\varepsilon)\varphi(y)t_0^{-d/2}e^{-C_2(\varepsilon)\tilde{\rho}(x,y)^2/8t_0}
\]

\[
\geq C_3(\varepsilon)\varphi(y)t_0^{-d/2}e^{-C_2(\varepsilon)C_3(\varepsilon)\rho(x,y)^2/8t_0}
\]

for some constants \( C_1(\varepsilon), C_2(\varepsilon), C_3(\varepsilon) > 1 \) with \( C_2(\varepsilon), C_3(\varepsilon) \to 1 \) as \( \varepsilon \to 0 \). Hence the proof is completed. \( \square \)

3. Gradient estimate for Dirichlet heat semigroup using coupling of diffusion processes

**Proposition 3.1.** Let \( D \) be a relatively compact \( C^2 \) domain in \( M \). For every compact subset \( K \) of \( D \), there exists a constant \( C = C(K,D) > 0 \) such that for all \( \delta > 0, t > 0, x_0 \in K \) and for all bounded positive functions \( f \) on \( M \),

\[
|\nabla P^D_t f(x_0)|
\]

\[
\leq \delta P^D_t \left( f \log \left( \frac{f}{P^D_t f(x_0)} \right), (x_0) \right) + C \left( \frac{1}{\delta(t \wedge 1)} + 1 \right) P^D_t f(x_0).
\]

**Proof.** We assume that \( t \in [0,1[ \), the other case will be treated at the very end of the proof.

We write \( \nabla V = Z \) so that \( L = \Delta + Z \). Since \( P^D_t \) only depends on the Riemannian metric and the vector field \( Z \) on the domain \( D \), by modifying the metric and \( Z \) outside of \( D \) we may assume that \( \text{Ric} - \nabla Z \) is bounded below (see e.g. [13]); that is,

\[
\text{Ric} - \nabla Z \geq -\kappa
\]

for some constant \( \kappa \geq 0 \).
Fix $x_0 \in K$. Let $f$ be a positive bounded function on $M$ and $X_s$ a diffusion with generator $L$, starting at $x_0$. For fixed $t \leq 1$, let

$$v = \frac{\nabla P_t^D f(x_0)}{|\nabla P_t^D f(x_0)|}$$

and denote by $u \mapsto \varphi(u)$ the geodesics in $M$ satisfying $\dot{\varphi}(0) = v$. Then

$$\left. \frac{d}{du} \right|_{u=0} P_t^D f(\varphi(u)) = |\nabla P_t^D f(x_0)|.$$

To formulate the coupling used in [1], we introduce some notations.

If $Y$ is a semimartingale in $M$, we denote by $dY$ its Itô differential and by $d_m Y$ the martingale part of $dY$: in local coordinates,

$$dY = \left( dy^i + \frac{1}{2} \Gamma^i_{jk}(x) \, dy^j \, dy^k \right) \frac{\partial}{\partial x^i}$$

where $\Gamma^i_{jk}$ are the Christoffel symbols of the Levi-Civita connection; if $dY^i = dM^i + dA^i$ where $M^i$ is a local martingale and $A^i$ a finite variation process, then

$$d_m Y = dM^i \frac{\partial}{\partial x^i}.$$  

Alternatively, if $Q(Y) : T_{Y_0} M \to T_Y M$ is the parallel translation along $Y$, then

$$dY_t = Q(Y)_t \, d \left( \int_0^t Q(Y)_s^{-1} \circ dY_s \right)_t$$

and

$$d_m Y_t = Q(Y)_t \, dN_t$$

where $N_t$ is the martingale part of the Stratonovich integral $\int_0^t Q(Y)_s^{-1} \circ dY_s$.

For $x, y \in M$, and $y$ not in the cut-locus of $x$, let

$$(3.3) \quad I(x, y) = \sum_{i=1}^{d-1} \int_0^{\rho(x, y)} \left( |\nabla \bar{e}(x, y) J_i|^2 + \langle R(\bar{e}(x, y), J_i) J_i + \nabla \bar{e}(x, y) Z, \bar{e}(x, y) \rangle \right)_s \, ds$$

where $\bar{e}(x, y)$ is the tangent vector of the unit speed minimal geodesic $e(x, y)$ and $(J_i)_{i=1}^d$ are Jacobi fields along $e(x, y)$ which together with $\bar{e}(x, y)$ constitute an orthonormal basis of the tangent space at $x$ and $y$:

$$J_i(\rho(x, y)) = P_{x,y} J_i(0), \quad i = 1, \ldots, d - 1;$$

here $P_{x,y} : T_x M \to T_y M$ is the parallel translation along the geodesic $e(x, y)$.

Let $c \in ]0, 1[$. For $h > 0$ but smaller than the injectivity radius of $D$, and $t > 0$, let $X^h$ be the semimartingale satisfying $X^h_0 = \varphi(h)$ and

$$(3.4) \quad dX^h_s = P_{X_s, X^h_s} \, d_m X_s + Z(X^h_s) \, ds + \xi^h_s \, ds,$$

where

$$\xi^h_s := \left( \frac{h}{ct} + \kappa h \right) n(X^h_s, X_s)$$

with $n(X^h_s, X_s)$ the derivative at time 0 of the unit speed geodesic from $X^h_s$ to $X_s$, and $P_{X_s, X^h_s} : T_{X_s} M \to T_{X^h_s} M$ the parallel transport along the minimal geodesic from $X_s$ to $X^h_s$. By convention, we put $n(x, x) = 0$ and $P_{x, x} = \text{Id}$ for all $x \in M$. 

By the second variational formula and (3.2) (cf. [1]), we have

\[
d\rho(X_s, X_s^h) \leq \left\{ I(X_s, X_s^h) - \frac{h}{ct} - \kappa h \right\} ds \leq - \frac{h}{ct} ds, \quad s \leq T_h,
\]

where \(T_h := \inf\{s \geq 0 : X_s = X_s^h\}\). Thus, \((X_s, X_s^h)\) never reaches the cut-locus. In particular, \(T_h \leq ct\) and

\[
(3.5) \quad X_s = X_s^h, \quad s \geq ct.
\]

Moreover, we have \(\rho(X_s, X_s^h) \leq h\) and

\[
(3.6) \quad |\xi_s^h|^2 \leq h^2 \left( \kappa + \frac{1}{ct} \right)^2.
\]

We want to compensate the additional drift of \(X^h\) by a change of probability. To this end, let

\[
M_s^h = - \int_0^{s \wedge ct} \langle \xi_r^h, P_{X_r, X_r^h} d\mu X_r \rangle,
\]

and

\[
R_s^h = \exp \left( M_s^h - \frac{1}{2} [M^h]_s \right).
\]

Clearly \(R^h\) is a martingale, and under \(Q^h = R^h \cdot P\), the process \(X^h\) is a diffusion with generator \(L\).

Letting \(\tau(x_0)\) (resp. \(\tau^h\)) be the hitting time of \(\partial D\) by \(X\) (resp. by \(X^h\)), we have

\[
1_{\{t < \tau^h\}} \leq 1_{\{t < \tau(x_0)\}} + 1_{\{\tau(x_0) \leq t < \tau^h\}}.
\]

But, since \(X_s^h = X_s\) for \(s \geq ct\), we obtain

\[
1_{\{\tau(x_0) \leq t < \tau^h\}} = 1_{\{\tau(x_0) \leq ct\}} 1_{\{t < \tau^h\}}.
\]

Consequently,

\[
\frac{1}{h} \left( P_t^D f(\varphi(h)) - P_t^D f(x_0) \right) = \frac{1}{h} \mathbb{E} \left[ f(X_t^h) R_t^h 1_{\{t < \tau^h\}} - f(X_t(0)) 1_{\{t < \tau(x_0)\}} \right]
\]

\[
\leq \frac{1}{h} \mathbb{E} \left[ f(X_t^h) R_t^h 1_{\{t < \tau(x_0)\}} - f(X_t(0)) 1_{\{t < \tau(x_0)\}} \right]
\]

\[
+ \frac{1}{h} \mathbb{E} \left[ f(X_t^h) R_t^h 1_{\{\tau(x_0) \leq ct\}} 1_{\{t < \tau^h\}} \right],
\]

and since \(X_t^h = X_t\) this yields

\[
(3.7) \quad \frac{1}{h} \left( P_t^D f(\varphi(h)) - P_t^D f(x_0) \right) \leq \mathbb{E} \left[ f(X_t) 1_{\{t < \tau(x_0)\}} \frac{1}{h} (R_t^h - 1) \right]
\]

\[
+ \frac{1}{h} \mathbb{E} \left[ f(X_t^h) R_t^h 1_{\{\tau(x_0) \leq ct\}} 1_{\{t < \tau^h\}} \right].
\]

The left hand side converges to the quantity to be evaluated as \(h\) goes to 0. Hence, it is enough to find appropriate \(\limsup\)'s for the two terms of the right hand side. We begin with the first term. Letting

\[
Y_s^h = \left| M_s^h - \frac{1}{2} [M^h]_s \right|
\]
and noting that \( \langle n(X^h_t, X_t), P_{X^h_t \cdot X^h_t} \rangle \) = \( \sqrt{2} dB_t \) up to the coupling time \( T_h \) for some one-dimensional Brownian motion \( b_t \), we have

\[
R^h_t = \exp \left( M^h_t - \frac{1}{2} |M^h_t| \right) \leq 1 + M^h_t - \frac{1}{2} |M^h_t| + (Y^h_t)^2 \exp(Y^h_t)
\]

\[
= 1 + M^h_t - \int_0^t |\xi^h_s|^2 ds + (Y^h_t)^2 \exp(Y^h_t).
\]

From the assumptions, \( \exp(Y^h_t) \) and \( Y^h_t / h \) have all their moments bounded, uniformly in \( h > 0 \). Consequently, since \( f \) is bounded,

\[
\lim_{h \to 0} \sup \mathbb{E} \left[ f(X_t) 1_{\{t < \tau(x_0)\}} \frac{1}{h} \left( \int_0^t |\xi^h_t|^2 dt + (Y^h_t)^2 \exp(Y^h_t) \right) \right] = 0,
\]

which implies

\[
\lim_{h \to 0} \sup \mathbb{E} \left[ f(X_t) 1_{\{t < \tau(x_0)\}} \frac{1}{h} (R^h_t - 1) \right] \leq \lim_{h \to 0} \sup \mathbb{E} \left[ f(X_t) 1_{\{t < \tau(x_0)\}} \frac{1}{h} \int_0^s \langle \xi^h_r, P_{X^h_r} \rangle d_m X_r \right].
\]

Using Lemma 2.4 and estimate (3.6), we have for \( \delta > 0 \)

\[
\mathbb{E} \left[ f(X_t) 1_{\{t < \tau(x_0)\}} \frac{1}{h} \int_0^s \langle \xi^h_r, P_{X^h_r} \rangle d_m X_r \right] \leq \delta P^D_t \left( f \log \left( \frac{f}{P^D_t f(x_0)} \right) \right) (x_0) + \delta P^D_t f(x_0) \log \mathbb{E} \left[ 1_{\{t < \tau(x_0)\}} \exp \left( \frac{1}{\delta h} \int_0^{ct} \langle \xi^h_s, P_{X^h_s} \rangle d_m X_s \right) \right]
\]

\[
\leq \delta P^D_t \left( f \log \left( \frac{f}{P^D_t f(x_0)} \right) \right) (x_0) + \delta P^D_t f(x_0) \log \mathbb{E} \left[ \exp \left( \frac{1}{\delta^2 h^2} \int_0^{ct} |\xi^h_s|^2 ds \right) \right]
\]

\[
\leq \delta P^D_t \left( f \log \left( \frac{f}{P^D_t f(x_0)} \right) \right) (x_0) + \delta P^D_t f(x_0) \frac{ct}{\delta t} \left( \frac{1}{ct^2} + \kappa^2 \right) + \delta P^D_t f(x_0) \frac{C'}{ct \delta t} P^D_t f(x_0),
\]

where \( C' = 1 + (ct)^2 \) (recall that \( t \leq 1 \)). Since the last expression is independent of \( h \), this proves that

\[
\lim_{h \to 0} \sup \mathbb{E} \left[ f(X_t) 1_{\{t < \tau(x_0)\}} \frac{1}{h} (R^h_t - 1) \right] \leq \delta P^D_t \left( f \log \left( \frac{f}{P^D_t f(x_0)} \right) \right) (x_0) + \frac{C'}{ct \delta t} P^D_t f(x_0).
\]

We are now going to estimate \( \limsup \) of the second term in (3.7). By the strong Markov property, we have

\[
\mathbb{E} \left[ f(X^h_t) R^h_t 1_{\{\tau(x_0) \leq ct\}} 1_{\{t < \tau^h\}} \right] = \mathbb{E}^x \left[ P^D_{ct, t} f(X^h_{ct}) 1_{\{\tau(x_0) \leq ct < \tau^h\}} \right]
\]

\[
\leq \|P^D_{ct, t}\|_\infty \mathbb{Q}^h \{ \tau(x_0) \leq ct < \tau^h \}.
\]
Since $\rho(X^h_s, X_s) \leq h \frac{ct - s}{ct}$ for $s \in [0, ct]$, we have on $\{\tau(x_0) \leq ct < \tau^h\}$:

$$\rho_{\partial D}(X^h_{\tau(x_0)}) \leq h \frac{ct - \tau(x_0)}{ct}.$$  

For $s \in [0, \tau^h - \tau(x_0)]$, define

$$Y'_s = \rho(X^h_{\tau(x_0) + s}, \partial D),$$

and for fixed small $\varepsilon > 0$ (but $\varepsilon > h$), let $S' = \inf\{s \geq 0, Y'_s = \varepsilon \text{ or } Y'_s = 0\}$. Since under $Q^h$ the process $X^h_s$ is generated by $L$, the drift of $\rho(X^h_s, \partial D)$ is $L\rho(\cdot, \partial D)$ which is bounded in a neighborhood of $\partial D$. Thus, for a sufficiently small $\varepsilon > 0$, there exists a $Q^h$-Brownian motion $\beta$ started at 0, and a constant $N > 0$ such that

$$Y_s := h \frac{ct - \tau(x_0)}{ct} + \sqrt{2}\beta_s + Ns \geq Y'_s, \quad s \in [0, S'].$$

Let

$$S = \inf\{u \geq 0, Y_u = \varepsilon \text{ or } Y_u = 0\}.$$  

Taking into account that on $\{\tau(x_0) = u\}$,

$${Y'_S, = \varepsilon} \cup \{S' > ct - u\} \subset \{Y_S = \varepsilon\} \cup \{S > ct - u\},$$

we have for $u \in [0, ct]$,

$$Q^h\{ct < \tau^h|\tau(x_0) = u\} \leq Q^h\{Y_S = \varepsilon|\tau(x_0) = u\} + Q^h\{S' \geq ct - u|\tau(x_0) = u\} = Q^h\{Y_S = \varepsilon|\tau(x_0) = u\} + \frac{1}{ct - u}E_{Q^h}[S|\tau(x_0) = u].$$

Now using the fact that $e^{-NY_s}$ is a martingale and $Y^2_s - 2s$ a submartingale, we get

$$Q^h\{Y_S = \varepsilon|\tau(x_0) = u\} = \frac{1 - e^{-N\frac{ct - u}{e^{\tau(x_0)}}}}{1 - e^{-Ne\varepsilon}} \leq C_1 h$$

and

$$E_{Q^h}[S|\tau(x_0) = u] \leq E_{Q^h}[Y^2_S|\tau(x_0) = u] \leq \varepsilon^2 Q^h\{Y_S = \varepsilon|\tau(x_0) = u\} = \varepsilon^2 \frac{1 - e^{-N\frac{ct - u}{e^{\tau(x_0)}}}}{1 - e^{-Ne\varepsilon}} \leq C_2 \frac{h(ct - u)}{ct}$$

for some constants $C_1, C_2 > 0$. Thus,

$$Q^h\{ct < \tau^h|\tau(x_0) = u\} \leq C_1 h + \frac{1}{ct - u}C_2 \frac{h(ct - u)}{ct} \leq C_1 h + C_3 \frac{h}{ct} \leq C_4 \frac{h}{t}.$$
for some constants $C_3, C_4 > 0$ (recall that $t \leq 1$). Denoting by $\ell^h$ the density of $\tau(x_0)$ under $Q^h$, this implies

$$Q^h \{\tau(x_0) \leq ct < \tau^h \} = \int_0^{ct} \ell^h(u) Q^h \{ct < \tau^h | \sigma^h = u\} \, du$$

$$\leq C_4 h^t \int_0^{ct} \ell^h(u) \, du$$

$$= C_4 h^t Q^h \{\tau(x_0) \leq ct\}.$$  

In terms of $D^{-h} = \{x \in D, \, \rho_D(x) > h\}$ and $\sigma^h = \inf\{s > 0, \, X_s^h \in \partial D^{-h}\}$, we have $\sigma^h \leq \tau(x_0)$ a.s. Hence, by Lemma 2.3

$$Q^h \{\tau(x_0) \leq ct\} \leq Q^h \{\sigma^h \leq ct\} \leq C \exp \left\{ - \frac{\rho_D^{-\kappa}(\varphi(h))}{16ct} \right\},$$

where we used that $X_s^h$ is generated by $L$ under $Q^h$. This implies

$$Q^h \{\tau(x_0) \leq ct < \tau^h \} \leq C_4 h^t \exp \left\{ - \frac{\rho_D^{-\kappa}(\varphi(h))}{16ct} \right\}.$$  

Since $\frac{1}{h} (P_t^D(\varphi(h)) - P_t^D(x_0))$ converges to $|\nabla P_t^D f(x_0)|$, we obtain from (3.7), (3.8), (3.9) and (3.10),

$$|\nabla P_t^D f(x_0)| \leq \delta P_t^D \left( f \log \left( \frac{f}{P_t^D f(x_0)} \right) \right)(x_0)$$

$$+ \frac{C'}{\delta t} P_t^D f(x_0) + C_5 \|P_t^D f\|_{\infty} \frac{1}{t} \exp \left\{ - \frac{\rho_D(x_0)}{16ct} \right\}.$$  

Finally, as explained in steps c) and d) of the proof of Proposition 2.5 for any compact set $K \subset D$, there exists a constant $C(K, D) > 0$ such that

$$\|P_t^D f\|_{\infty} \leq e^{C(K, D)/t} P_t^D f(x_0), \quad c \in [0, 1/2], \, x_0 \in K, \, t \in [0, 1].$$

Combining this with (3.11), we arrive at

$$|\nabla P_t^D f(x_0)| \leq \delta P_t^D \left( f \log \left( \frac{f}{P_t^D f(x_0)} \right) \right)(x_0)$$

$$+ C_5 \frac{1}{t} \exp \left\{ - \frac{\rho_D(x_0)}{16ct} \right\} \exp \left\{ \frac{C(K, D)}{t} \right\} P_t^D f(x_0).$$  

Finally, choosing $c$ such that

$$0 < c < \frac{1}{2} \wedge \frac{\text{dist}(K, \partial D)}{16C(K, D)},$$

we get for some constant $C > 0$,

$$|\nabla P_t^D f(x_0)| \leq \delta P_t^D \left( f \log \left( \frac{f}{P_t^D f(x_0)} \right) \right)(x_0) + C \left( \frac{1}{\delta t} + 1 \right) P_t^D f(x_0),$$

$$x_0 \in K, \, \delta > 0,$$

which implies the desired inequality.
To finish we consider the case $t > 1$. From the semigroup property, we have $P_t^Df = P_t^D(P_{t-1}^Df)$. So letting $g = P_{t-1}^Df$ and applying (3.13) to $g$ at time 1, we obtain

$$|\nabla P_t^Df(x_0)| \leq \delta P_1^D \left( g \log \left( \frac{g}{P_1^D g(x_0)} \right) \right)(x_0) + C \left( \frac{1}{\delta} + 1 \right) P_1^D g(x_0).$$

Now using $P_1^Dg = P_t^Df$, we get

$$|\nabla P_t^Df(x_0)| \leq \delta P_1^D (g \log g)(x_0) - P_1^Df(x_0) \log P_1^Df(x_0) + C \left( \frac{1}{\delta} + 1 \right) P_1^Df(x_0).$$

Letting $\phi(x) = x \log x$, we have for $z \in D$

$$g \log g = \phi \left( \mathbb{E} [f(X_{t-1}(z))1_{(t-1 < \tau(z))}] \right) \leq \mathbb{E} \left[ \phi (f(X_{t-1}(z))1_{(t-1 < \tau(z))}) \right] = \mathbb{E} \left[ \phi(f)(X_{t-1}(z))1_{(t-1 < \tau(z))} \right] = P_{t-1}^D(f \log f)(z),$$

where we successively used the convexity of $\phi$ and the fact that $\phi(0) = 0$. This implies

$$|\nabla P_t^Df(x_0)| \leq \delta P_1^D \left( f \log \left( \frac{f}{P_1^D f(x_0)} \right) \right)(x_0) + C \left( \frac{1}{\delta} + 1 \right) P_1^D f(x_0),$$

which is the desired inequality for $t > 1$.

\[ \square \]

4. Proof of Theorems 1.1 and Theorem 1.2

of Theorem 1.1 We assume that $t \in [0,1]$ and refer to the end of the proof of Proposition 3.1 for the case $t > 1$. Fixing $\delta > 0$ and $x_0 \in M$, we take $R = 160/(\delta \wedge 1)$. Let $D$ be a relatively compact open domain with $C^2$ boundary containing $B(x_0,2R)$ and contained in $B(x_0,2R+\varepsilon)$ for some small $\varepsilon > 0$. By the countable compactness of $M$, it suffices to prove that there exists a constant $C = C(D)$ such that (1.4) holds on $B(x_0,R)$ with $C$ in place of $F(\delta \wedge 1, x_0)$. We now fix $x \in B(x_0,R)$, $t \in [0,1]$ and $f \in \mathcal{D}_0^\delta$. Without loss of generality, we may and will assume that $P_tf(x) = 1$.

(a) Let $P_s(x,dy)$ be the transition kernel of the $L$-diffusion process, and for $x \in D$, $z \in M$, let

$$\nu_s(x,dz) = \int_{\partial D} h_x(s/2,y) P_{t-s}(y,dz) \nu(dy),$$

where $\nu$ is the measure on $\partial D$ induced by $\mu(dy) = e^{V(y)}dy$. By Lemma 2.2 we have

$$P_tf(x) = P_t^Df(x) + \int_{[0,t] \times D \times M} P_{s/2}^D(x,y)f(z) d\mu(dy)\nu_s(y,dz).$$

Then

$$|\nabla P_t^Df(x)| \leq |\nabla P_t^Df(x)| + \int_{[0,t] \times D \times M} |\nabla \log p_{s/2}^D(\cdot,y)(x)| P_{s/2}^D(x,y)f(z) d\mu(dy)\nu_s(y,dz)$$

(4.1) $$=: I_1 + I_2.$$
(b) By Proposition 3.1 we have
\[
I_1 \leq \delta P_t^D(f \log f)(x) + \frac{\delta}{e} + C \left( \frac{1}{\delta t} + 1 \right), \quad x \in B(x_0, R), \ t \in [0, 1], \ \delta > 0
\]
for some $C = C(D) > 0$.

(c) By Proposition 2.5 with $\varepsilon = 1$, we have
\[
I_2 \leq \int_{[0,t] \times M \times D} \left[ \frac{C \log(e + s^{-1})}{\sqrt{s}} + \frac{2\rho(x, y)}{s} \right] p_{s/2}^D(x, y) f(s) ds \nu_s(y, dz) d\mu(dy)
\]
for some $C = C(D) > 0$ and all $t \in [0, 1]$. Applying Lemma 2.4 to the measure $\tilde{\mu} := p_{s/2}^D(x, y) d\nu_s(y, dz) d\mu(dy)$ on $E := [0, t] \times M \times D$ so that
\[
\tilde{\mu}(E) = \mathbb{P}(\tau(x) \leq t < \xi(x)) \leq 1,
\]
we obtain
\[
I_2 \leq \delta \mathbb{E} \left[ (f \log f)(X_t(x)) 1_{\{\tau(x) \leq t < \xi(x)\}} \right] + \frac{\delta}{e} + \delta \mathbb{E} \left[ f(X_t(x)) 1_{\{\tau(x) \leq t < \xi(x)\}} \right]
\]
\[
\times \log \int_{[0,t] \times M \times D} \exp \left\{ \frac{C \log(e + s^{-1})}{\sqrt{s}} + \frac{2\rho(x, y)}{s} \right\} ds p_{s/2}^D(x, y) \nu_s(y, dz) d\mu(dy)
\]
\[
\leq \delta \mathbb{E} \left[ (f \log f)(X_t(x)) 1_{\{\tau(x) \leq t < \xi(x)\}} \right] + \frac{\delta}{e} + \delta \mathbb{E} \left[ f(X_t(x)) 1_{\{\tau(x) \leq t < \xi(x)\}} \right]
\]
\[
\times \log \int_{[0,t] \times M \times D} \exp \left\{ \frac{A}{\delta} + \frac{9R}{s \delta} \right\} ds p_{s/2}^D(x, y) \nu_s(y, dz) d\mu(dy),
\]
where
\[
A := \sup_{r > 0} \left\{ C \sqrt{r} \log(e + r) - r \right\} < \infty.
\]
We get
\[
I_2 \leq \delta \mathbb{E} \left[ (f \log f)(X_t(x)) 1_{\{\tau(x) \leq t < \xi(x)\}} \right] + \frac{\delta}{e}
\]
\[
+ \delta \mathbb{E} \left[ f(X_t(x)) 1_{\{\tau(x) \leq t < \xi(x)\}} \right] \left( \log \mathbb{E} \left[ \exp \left( \frac{9R}{\delta \tau(x)} \right) \right] + \frac{A}{\delta} \right)
\]
\[
\leq \delta \mathbb{E} \left[ (f \log f)(X_t(x)) 1_{\{\tau(x) \leq t < \xi(x)\}} \right] + \frac{\delta}{e} + \delta \log \mathbb{E} \left[ \exp \left( \frac{9R}{\delta \tau(x)} \right) \right] + A
\]
\[
\leq \delta \mathbb{E} \left[ (f \log f)(X_t(x)) 1_{\{\tau(x) \leq t < \xi(x)\}} \right] + \delta \log \mathbb{E} \left[ \exp \left( \frac{9R}{(\delta + 1) \tau(x)} \right) \right] + A + \frac{\delta}{e}
\]
\[
= \delta \mathbb{E} \left[ (f \log f)(X_t(x)) 1_{\{\tau(x) \leq t < \xi(x)\}} \right] + (\delta + 1) \log \mathbb{E} \left[ \exp \left( \frac{9R}{(\delta + 1) \tau(x)} \right) \right] + A + \frac{\delta}{e}.
\]
By Lemma 2.3 and noting that \( \rho(x) \geq R \), we have

\[
\begin{align*}
\mathbb{E} \left[ \exp \left( \frac{9R}{\delta \wedge 1} \tau(x) \right) \right] & \leq 1 + \mathbb{E} \left[ \exp \left( \frac{9R}{\delta \wedge 1} \tau(x) \right) \right] \\
& = 1 + \int_{0}^{\infty} \frac{9Rs}{(\delta \wedge 1)} \exp \left( \frac{9Rs}{(\delta \wedge 1)} \right) \frac{d}{ds} \left( -\mathbb{P}\{\tau(x) \leq s^{-1}\} \right) ds \\
& = 1 + \frac{9R}{(\delta \wedge 1)} \int_{0}^{\infty} \left( \frac{9R}{(\delta \wedge 1)} s + 1 \right) \exp \left( \frac{9Rs}{(\delta \wedge 1)} \right) \mathbb{P}\{\tau(x) \leq s^{-1}\} ds \\
& \leq 1 + \frac{9R}{(\delta \wedge 1)} \int_{0}^{\infty} \left( \frac{9R}{(\delta \wedge 1)} s + 1 \right) \exp \left( \frac{9Rs}{(\delta \wedge 1)} \right) ds \\
& = 1 + 9 \int_{0}^{\infty} (9u + 1) \exp(-u) du =: A',
\end{align*}
\]

since \( R = 160/(\delta \wedge 1) \). This along with (4.5) yields

\[
(4.6) \quad I_2 \leq \delta \mathbb{E} \left[ (f \log f)(X_t(x))1_{\{\tau(x) \leq \xi(x)\}} \right] + \log A' + A + \frac{\delta}{e}.
\]

The proof is completed by combining (4.6) with (3.1), (4.2) and (4.4).

of Theorem 1.2. By Theorem 1.1

\[
|\nabla P_t f(x)| \leq \delta (P_t(f \log f)(x) - (P_t f)(x) \log P_t f(x))
\]

(4.7) \quad + \left( F(\delta \wedge 1, x) \left( \frac{1}{\delta(t \wedge 1)} + 1 \right) + \frac{2\delta}{e} \right) P_t f(x), \quad \delta > 0, \ x \in M.
\]

For \( \alpha > 1 \) and \( x \neq y \), let \( \beta(s) = 1 + s(\alpha - 1) \) and let \( \gamma : [0, 1] \rightarrow M \) be the minimal geodesic from \( x \) to \( y \). Then \( |\gamma| = \rho(x, y) \). Applying (1.7) with \( \delta = \frac{\alpha - 1}{\alpha \rho(x, y)} \), we obtain

\[
\frac{d}{ds} \log(P_t f^{\beta(s)}(\gamma_s)) = \frac{\alpha(\alpha - 1)}{\beta(s)^2} P_t f^{\beta(s)}(\gamma_s) \left( \frac{\alpha - 1}{\alpha \rho(x, y)} \right) (P_t f^{\beta(s)}(\gamma_s) - (P_t f^{\beta(s)})(\gamma_s)) \]

\[
\geq \frac{\alpha \rho(x, y)}{\beta(s)^2} P_t f^{\beta(s)}(\gamma_s) \left( \frac{\alpha - 1}{\alpha \rho(x, y)} \right) \left( P_t f^{\beta(s)}(\gamma_s) - (P_t f^{\beta(s)})(\gamma_s) \right)
\]

\[
\geq F \left( \frac{\alpha - 1}{\alpha \rho(x, y)} \wedge 1, \gamma_s \right) \left( \frac{\alpha^2 \rho^2(x, y)}{\beta(s) (\alpha - 1)(t \wedge 1)} + \frac{\alpha \rho(x, y)}{\beta(s)} \right) - \frac{2(\alpha - 1)}{e \beta(s)}
\]

\[
\geq C(\alpha, x, y) \left( \frac{\alpha \rho^2(x, y)}{(\alpha - 1)(t \wedge 1)} + \rho(x, y) \right) - \frac{2(\alpha - 1)}{e}
\]

where \( C(\alpha, x, y) := \sup_{s \in [0, 1]} \frac{1}{\alpha} F \left( \frac{\alpha - 1}{\alpha \rho(x, y)} \wedge 1, \gamma_s \right) \). This implies the desired Harnack inequality.
Next, for fixed $\alpha \in [1, 2[$, let

$$K(\alpha, t, x) = \sup \{ C(\alpha, x, y) : y \in B(x, \sqrt{2t}) \}, \quad t > 0, \ x \in M.$$  

Note $K(\alpha, t, x)$ is finite and continuous in $(\alpha, t, x) \in ]1, 2[ \times ]0, 1[ \times M$. Let $p := 2/\alpha$.

For fixed $t \in ]0, 1[$, the Harnack inequality gives for $y \in B(x, \sqrt{2t})$,

$$(P_t f(x))^2 \leq (P_t f^\alpha(y))^p \exp \left\{ \frac{2(2 - p)}{e} - 2K(\alpha, t, x) \left( \frac{2\alpha}{\alpha - 1} + \sqrt{2t} \right) \right\}.$$  

Then choosing $T > t$ such that $q := p/(p - 1) < T/t$,

$$\mu(B(x, \sqrt{2T})) \exp \left\{ -\frac{2(2 - p)}{e} - 2K(\alpha, t, x) \left( \frac{2\alpha}{\alpha - 1} + \sqrt{2t} \right) - \frac{t}{T - qt} \right\} (P_t f(x))^2$$

$$\leq \int_{B(x, \sqrt{2T})} (P_t f^\alpha(y))^p \exp \left\{ -\frac{\rho(x, y)^2}{2(T - qt)} \right\} \mu(dy).$$  

Similarly to the proof of [1] Corollary 3, we obtain that for any $\delta > 2$, choosing $\alpha = \frac{2\delta}{2 + \delta} \in ]1, 2[$ such that $\delta > \frac{2}{2 - \alpha} = \frac{4}{p - 1} > 2$, there is a constant $c(\delta) > 0$ such that the following estimate holds:

$$E_{\delta}(x, t) := \int_M p_t(x, y)^2 \exp \left\{ \frac{\rho(x, y)^2}{\delta t} \right\} \mu(dy) \leq \exp \left\{ c(\delta)K(\alpha, t, x)(1 + \sqrt{2t}) \right\} \mu(B(x, \sqrt{2T})),$$  

$t > 0, \ x \in M$.

By [6] Eq. (3.4)], this implies the desired heat kernel upper bound for $C_{\delta}(t, x) := c(\delta)K(\alpha, t, x)(1 + \sqrt{2t})$. \hfill \Box

5. APPENDIX

The aim of the Appendix is to explain that the arguments in Souplet-Zhang [13] and Zhang [19] for gradient estimates of solutions to heat equations work as well in the case with drift.

**Theorem 5.1.** Let $L = \Delta + Z$ for a $C^1$ vector field $Z$. Fix $x_0 \in M$ and $R$, $T$, $t_0 > 0$ such that $B(x_0, R) \subset M$. Assume that

$$\text{Ric} - \nabla Z \geq -K$$  

on $B(x_0, R)$. There exists a constant $c$ depending only on $d$, the dimension of the manifold, such that for any positive solution $u$ of

$$\partial_t u = Lu$$  

on $Q_{R, T} := B(x_0, R) \times [t_0 - T, t_0]$, the estimate

$$|\nabla \log u| \leq c \left( \frac{1}{R} + T^{-1/2} + \sqrt{K} \right) \left( 1 + \log \sup_{Q_{R, T}} u \right)$$

holds on $Q_{R/2, T/2}$.

**Proof.** Without loss of generality, let $N := \sup_{Q_{T, R}} u = 1$; otherwise replace $u$ by $u/N$. Let $f = \log u$ and $\omega = \frac{||\nabla f||^2}{(1 + f)^2}$. By (5.2) we have

$$Lf + ||\nabla f||^2 - \partial_t f = 0$$
so that
\[
\partial_\omega = \frac{2(\nabla f, \nabla \partial_\omega f)}{(1 - f)^2} + \frac{2|\nabla f|^2 \partial_\omega f}{(1 - f)^3}
\]
\[
= \frac{2(\nabla f, \nabla (Lf + |\nabla f|^2))}{(1 - f)^2} + \frac{2|\nabla f|^2 (Lf + |\nabla f|^2)}{(1 - f)^3}
\]
\[
+ \frac{2(\nabla \nabla_f Z, \nabla f) + 2\text{Hess}_f(\nabla f, Z)}{(1 - f)^2} + \frac{2|\nabla f|^2 (Z, \nabla f)}{(1 - f)^3}.
\]

Moreover,
\[
L\omega = \Delta \omega + \frac{(Z, |\nabla f|^2)}{(1 - f)^2} + \frac{2|\nabla f|^2 (Z, \nabla f)}{(1 - f)^3}
\]
\[
= \Delta \omega + \frac{2\text{Hess}_f(\nabla f, Z)}{(1 - f)^2} + \frac{2|\nabla f|^2 (Z, \nabla f)}{(1 - f)^3}.
\]

Finally, by the proof of [13, (2.9)] with \(-k\) replaced by \(\text{Ric}(\nabla f, \nabla f)/|\nabla f|^2\), we obtain
\[
\Delta \omega - \left\{ \frac{2(\nabla f, \nabla (\Delta f + |\nabla f|^2))}{(1 - f)^2} + \frac{2|\nabla f|^2 (\Delta f + |\nabla f|^2)}{(1 - f)^3} \right\}
\]
\[
\geq \frac{2f}{1 - f}(\nabla f, \nabla \omega) + 2(1 - f)\omega^2 + \frac{2\omega \text{Ric}(\nabla f, \nabla f)}{|\nabla f|^2}.
\]

Combining [31], [53], [54] and [55], we arrive at
\[
L\omega - \partial_\omega \omega \geq \frac{2f}{1 - f}(\nabla f, \nabla \omega) + 2(1 - f)\omega^2 - 2K\omega.
\]

This implies the desired estimate by the Li-Yau cut-off argument as in [13]; the only difference is, using the notation in [13], in the calculation of \(-(\Delta \omega)\omega\) after Eq. (2.13) in [13]. By [31] and the generalized Laplacian comparison theorem (see [3, Theorem 4.2]), we have
\[
L\omega \leq \sqrt{Kd} \coth (\sqrt{K/d} r) \leq \frac{d}{r} + \sqrt{Kd},
\]
and then
\[
-(L\psi)\omega = -(\partial_\omega^2 \psi + (\partial_\omega \psi)L\omega) \leq \left( |\partial_\omega \psi|^2 + |\partial_\omega \psi|\frac{d}{r} + \sqrt{Kd} |\partial_\omega \psi| \right) \omega.
\]

The remainder of the proof is the same as in the proof of [13] Theorem 1.1, using \(L\psi\) in place of \(\Delta \psi\). \(\square\)
