The Roles of Cytochrome $b_{559}$ in Assembly and Photoprotection of Photosystem II Revealed by Site-Directed Mutagenesis Studies

Hsiu-An Chu* and Yi-Fang Chiu

Institute of Plant and Microbial Biology – Academia Sinica, Taipei, Taiwan

Cytochrome $b_{559}$ (Cyt $b_{559}$) is one of the essential components of the Photosystem II reaction center (PSII). Despite recent accomplishments in understanding the structure and function of PSII, the exact physiological function of Cyt $b_{559}$ remains unclear. Cyt $b_{559}$ is not involved in the primary electron transfer pathway in PSII but may participate in secondary electron transfer pathways that protect PSII against photoinhibition. Site-directed mutagenesis studies combined with spectroscopic and functional analysis have been used to characterize Cyt $b_{559}$ mutant strains and their mutant PSII complex in higher plants, green algae, and cyanobacteria. These integrated studies have provided important in vivo evidence for possible physiological roles of Cyt $b_{559}$ in the assembly and stability of PSII, protecting PSII against photoinhibition, and modulating photosynthetic light harvesting. This mini-review presents an overview of recent important progress in site-directed mutagenesis studies of Cyt $b_{559}$ and implications for revealing the physiological functions of Cyt $b_{559}$ in PSII.

Keywords: photosynthesis, photosystem II, cytochrome $b_{559}$, site-directed mutagenesis, photoprotection, photoinhibition

INTRODUCTION

Cytochrome $b_{559}$ is one of the essential components of Photosystem II in all oxygenic photosynthetic organisms (Whitmarsh and Pakrasi, 1996; Stewart and Brudvig, 1998; Guskov et al., 2009; Umena et al., 2011). Cyt $b_{559}$ is a heme-bridged heterodimer protein comprising one $\alpha$- and one $\beta$- subunit (encoded by the psbE and psbF genes) of 9 and 4 kDa, respectively (see Figure 1). Each subunit provides a His ligand (His-22 residue of the $\alpha$- or $\beta$-subunit of Cyt $b_{559}$ in Synechocystis sp. PCC 6803, corresponding to His-23 residue of $\alpha$- or His-24 residue of the $\beta$-subunit of Cyt $b_{559}$ in Thermosynechococcus elongatus) for the non-covalently bound heme, which is located near the stromal side of PSII. In addition, Cyt $b_{559}$ has different redox potential forms depending on the type of PSII preparations and treatments: a HP form with a midpoint redox potential of about $+400 \text{ mV}$, an IP form of about $+200 \text{ mV}$, and a LP form with a midpoint redox potential of about $0–80 \text{ mV}$ (Stewart and Brudvig, 1998; Roncell et al., 2001 and references therein). In intact PSII preparations, Cyt $b_{559}$ is mostly in the reduced HP form under...
ambient conditions. In inactive or less intact PSII preparations, Cyt b559 is typically in the LP or IP form and mostly oxidized (presumably by molecular oxygen) under ambient conditions (Barber and De Las Rivas, 1993; Poulson et al., 1995; Pospíšil et al., 2006).

Several studies have proposed that Cyt b559 participates in secondary electron transfer pathways that protect PSII against photoinhibition (see Figure 2; Heber et al., 1979; Falkowski et al., 1986; Thompson and Brudvig, 1988; Barber and De Las Rivas, 1993; Poulson et al., 1995; Magnuson et al., 1999; Faller et al., 2001; Tracewell and Brudvig, 2008 and references therein). In these models, the HP form of Cyt b559 is thought to donate its electron, via a β-carotene molecule (Car D2), to reduce highly oxidized chlorophyll radicals in PSII under donor-side photoinhibitory conditions (e.g., the oxygen-evolving complex is impaired or under assembly). Oxidized Cyt b559 may accept an electron from the acceptor side of PSII (Qb−, or reduced PQH2 from the pool), thus forming a cyclic pathway of electron transfer within PSII. On the other hand, when the electron transfer on the acceptor side of PSII is inhibited (e.g., under high-light conditions), the oxidized Cyt b559 might accept an electron from the acceptor side of PSII to prevent the formation of damaging singlet oxygen species (Nedbal et al., 1992; Vass et al., 1992; Barber and De Las Rivas, 1993; Bondarava et al., 2010). In addition, several different enzymatic functions of Cyt b559 have been proposed, such as superoxide dismutase (Ananyev et al., 1994) and PQH2 oxidase in intact PSII (Kruk and Strzalka, 1999, Kruk and Strzalka, 2001; Bondarava et al., 2003, 2010) and superoxide oxidase and reductase in tris-washed PSII (Tiwari and Pospíšil, 2009; Pospíšil, 2011). Moreover, a novel quinone-binding site (Qc) was identified close (about 15 Å) to the heme of Cyt b559 in the 2.9-Å PSII crystal structure from T. elongatus (Guskov et al., 2009). The occupancy of this Qc site with PQ (or PQH2) has been proposed to modulate the redox equilibration between Cyt b559 and the PQ pool (Kaminskaya et al., 2006, 2007; Kaminskaya and Shuvalov, 2013) or be involved in the exchange of PQ on the Qa site from the pool (Guskov et al., 2009). However, the Qc site was not detected in the more recent 1.9-Å PSII crystal structure (Umena et al., 2011). Despite the recent remarkable progress in understanding the structure and function of PSII, the exact function of Cyt b559 in PSII remains unclear.

This mini-review gives an overview of important progress in recent site-directed mutagenesis studies performed to reveal the physiological function(s) of Cyt b559 in PSII. More comprehensive reviews on the structure and functions of Cyt b559 are available (Whitmarsh and Pakrasi, 1996; Stewart and Brudvig, 1998; Faller et al., 2005; Pospíšil, 2011; Shinopoulos and Brudvig, 2012).

**FUNCTION IN ASSEMBLY AND STABILITY OF PSII REACTION CENTERS**

Prior mutagenesis studies with Synechocystis sp. PCC 6803, Chlamydomonas reinhardtii or Nicotiana tabacum showed no
stable PSII reaction centers assembled in the absence of either Cyt b_{559} subunit (Pakrasi et al., 1988, 1989, 1990; Morais et al., 1998; Swiatek et al., 2003; Suorsa et al., 2004). Several authors proposed that Cyt b_{559} plays an important structural role, such as being a nucleating factor, during the early stage of PSII assembly (Pakrasi et al., 1988; Morais et al., 1998; Komenda et al., 2004).

In addition, mutagenesis studies with *Synechocystis* sp. PCC 6803 showed that substituting either of the heme axial ligands (His22 of the α-subunit or His22 of the β-subunit of Cyt b_{559} in *Synechocystis* sp. PCC 6803) with Leu, Met, Glu, Gln, Tyr, Lys, Arg, or Cys abolished the photoautotrophic growth and severely diminished the assembly or stability of PSII in the mutant cells, except for H22Kα mutant cells, which were able to grow photoautotrophically and accumulated stable PSII reaction centers (~81% as compared with wild-type cells; Pakrasi et al., 1991; Hung et al., 2007, 2010). Electron paramagnetic resonance results indicated the displacement of one of the two axial ligands to the heme of Cyt b_{559} in H22Kα mutant reaction centers (Hung et al., 2010). In addition, H22Kα and Y18Sα (corresponding to Y19Sα in *T. elongatus*) in mutant PSII core complexes contained predominately the LP form of Cyt b_{559}. The findings support the concept that the redox properties of Cyt b_{559} are strongly influenced by the hydrophobicity and ligation environment of the heme (Krishtalik et al., 1993; Gadjieva et al., 1999; Roncel et al., 2001; Pospíšil and Tiwari, 2010).

Spectroscopic and functional characterizations of the cyanobacterium *Synechocystis* sp. PCC 6803 with mutation of charged residues on the cytoplasmic side of Cyt b_{559} in PSII have been reported (Chiu et al., 2013). All mutant cells grew photoautotrophically and assembled stable PSII. However, R7Eα, R17Eα, and R17Lβ mutant cells grew significantly slower and were more susceptible to photoinhibition as compared with wild-type cells. In addition, the PSII core complexes from R7Eα and R17Lβ cells contained predominantly the LP form of Cyt b_{559}. Electron paramagnetic resonance results indicated the displacement of one of the two axial ligands to the heme of Cyt b_{559} in the reaction centers of the R7Eα and R17Lβ mutants. In recent PSII crystal structural models (Guskov et al., 2009; Umema et al., 2011), the side chains of...
these Arg residues of Cyt b_{559} (corresponding to Arg8 and Arg18 residues of the α-subunit and Arg19 residue of the β-subunit of Cyt b_{559} in T. elongatus) are in close contact with the heme propionates of Cyt b_{559} (see Figure 1). Thus, the electrostatic interactions between these Arg residues and the heme propionates of Cyt b_{559} may affect the ligation structure and redox properties of the heme in Cyt b_{559} (Chiu et al., 2013).

Furthermore, mutagenesis studies of C. reinhardtii showed that the H23Yα, H23Mα, and H23Ca mutant cells were unable to grow photoautotrophically, were sensitive to photoinhibition, accumulated 10–20% of the PSII (compared to wild-type cells), and contained a disrupted heme pocket while still retaining significant O₂ evolution activity (Moraïs et al., 2001; Hamilton et al., 2014). Thus, the heme of Cyt b_{559} was not required for photosynthetic water oxidation by PSII (Moraïs et al., 2001). A recent study also presented evidence to ascribe the photoinhibition phenotype of H23Ca mutant cells to a faster rate of photodamage and an impaired PSII repair cycle (Hamilton et al., 2014). Hence, Cyt b_{559} may play important roles in the assembly, repair and maintenance of the PSII complex in vivo.

In the other recent mutant study of T. elongatus that took advantage of the robustness of the PSII variant with PsbA3 as the D1 subunit, the four constructed Cyt b_{559} mutants (H23Aα, H23Mα, Y19Fα, and T26Pα) grew photoautotrophically (T. elongatus is an obligate photoautotroph; Sugiuira et al., 2015). Although the H23Aα and H23Mα mutants assembled only an apo-Cyt b_{559}, the steady-state level of active PSII was comparable to that in the wild-type control. The results suggest that the heme has no structural role in the assembly of PSII in the presence of α- and β-subunits of Cyt b_{559}. This finding is in strong contrast to the Synechocystis sp. PCC 6803 mutant showing that proper coordination of the heme cofactor in Cyt b_{559} is important to the assembly or stability of PSII (Pakrasi et al., 1991; Hung et al., 2007). In addition, Cyt b_{559} mutant cells of T. elongatus showed no correlation between the rate of photoinhibition and the redox potential of the heme. However, the recovery of the oxygen-evolving activity of PSII after photoinhibition was significantly slower in these mutant cells. PsbA3 is the D1 isoform expressed in T. elongatus under high-light conditions (Nakamura et al., 2002; Kós et al., 2008). The high-light D1 isoform in cyanobacteria has a Glu instead of a Gln residue (for the low-light D1 isoform) at position 130 in the D1 protein sequence (for a review, see Mulo et al., 2009) and this Glu residue forms hydrogen-bonding interactions with pheophytinD1 (Dorlet et al., 2001; Shibuya et al., 2010). Cyanobacterial PSIIIs with the high-light D1 isoform showed increased photo-tolerance and accelerated non-radiative charge recombination (Tichy et al., 2003). This phototolerant property has been attributed to a photoprotection mechanism involving the redox potential of pheophytinD1, which enhances the probability for non-radiative recombination of the singlet radical pair and prevents the formation of potentially damaging ³P680 and singlet oxygen species (Vass and Cser, 2009; Sugiuira et al., 2014). Further investigation could determine whether PsbA3 may compensate the photoprotective function of Cyt b_{559} in the assembly and stability of PSII in these Cyt b_{559} mutant cells.

**FUNCTION IN PROTECTING PSII AGAINST PHOTOINHIBITION**

Numerous site-directed mutagenesis studies have investigated the role of Cyt b_{559} in protecting PSII against photoinhibition under high light. In the photoprotective PSII mutant, oxidized Cyt b_{559} may accept an electron from the acceptor side of PSII (Q₈⁻, Q₇C, or reduced PQH₂ from the pool). Previous mutant studies of dark-adapted leaves of the F26Sβ Cyt b_{559} tobacco mutant showed a greatly reduced PQ pool, conversion of the redox-potential form of Cyt b_{559} to the LP form, and photosynthetic activities sensitive to high light (Bondarava et al., 2003, 2010). In addition, R7Eα and R17Lβ Cyt b_{559} mutant cells of Synechocystis sp. PCC 6803 and R185α Cyt b_{559} mutant cells of T. elongatus showed markedly reduced PQ pools, altered redox-potential forms of Cyt b_{559}, and high susceptibility to light stress (Chiu et al., 2013; Guerrero et al., 2014). A defect in PQH₂ oxidase activity of Cyt b_{559} due to altered redox-potential forms of Cyt b_{559} in these mutant strains could explain their high susceptibility to strong light and greatly reduced PQ pools. Therefore, Cyt b_{559} may function as a PQH₂ oxidase to keep the PQ pool and the acceptor side of PSII oxidized in the dark, thereby preventing PSII from acceptor-side photoinhibition (Kruk and Strzalka, 1999, Kruk and Strzalka, 2001; Bondarava et al., 2003, 2010). However, one recent study reported no defect in PQH₂ oxidation in the dark in H23Ca mutant cells of C. reinhardtii, even though H23Ca mutant cells contained a disrupted heme-binding pocket of Cyt b_{559} and were sensitive to photoinhibition (Hamilton et al., 2014). Further studies are required to clarify this discrepancy. In addition, study of the 2.9-Å resolution PSII crystal structure reported the binding of Q₇C at a hydrophobic cavity near Cyt b_{559} (Guskov et al., 2009). Several spectroscopic studies have provided evidence that the occupancy of the Q₇C site by PQ (or PQH₂) may modulate the redox potential of Cyt b_{559} and mediate the redox equilibration between Cyt b_{559} and the PQ pool (Kaminskaya et al., 2006, 2007; Kaminskaya and Shuvalov, 2013). A recent study provided evidence of a possible one-electron oxidation of PQH₂ by Cyt b_{559} at the Q₇C site involved in the formation of a superoxide anion radical (Yadav et al., 2014). The above results are consistent with Cyt b_{559} possibly accepting an electron from PQH₂ via the Q₇C site in PSII. However, the Q₇C site was not present in the more recent 1.9-Å PSII crystal structure (Umema et al., 2011). Further investigations are needed to solve this important issue.

Spectroscopic and functional characterization of the H22Ka and Y185α Cyt b_{559} mutant cells of Synechocystis sp. PCC 6803 showed that both mutants have functional PSII and exhibited the normal period-four oscillation in oxygen yield (Hung et al., 2010). However, both mutants were more susceptible to photoinhibition than the wild type under high-light conditions. In addition, PSII core complexes from the H22Ka and Y185α
mutants predominantly contained the oxidized LP form of Cyt b559 (~79 and 86%, respectively). A defect in the photoprotective function of Cyt b559 in H22Ko and Y18Sa mutants could explain their high susceptibility to strong light. Furthermore, H22Ko and Y18Sa Cyt b559 mutants in a D1-D170A genetic background that prevented assembly of the Mn cluster showed almost completely abolished accumulation of PSII even under normal-growth-light conditions. The data support an important redox role of Cyt b559 in protecting PSII under donor-side photoinhibition conditions (Hung et al., 2010).

Furthermore, under low light, the H23Ca Cyt b559 mutant showed more rapid assembly of the Mn4CaO5 cluster than the wild-type control in C. reinhardtii (Hamilton et al., 2014). However, the photoactivation of oxygen-evolving PSII in the H23Ca mutant was inhibited under high light. The results suggest that reduction of P680+ via cyclic electron flow within PSII (via Cyt b559 and Car(559)) may compete with the photoactivation process and provides important in vivo evidence for a photoprotective role of Cyt b559 in photo-assembly of the Mn4CaO5 cluster in PSII (Hamilton et al., 2014).

A recent mutant study involving T. elongatus showed that the midpoint redox potential of the HP form of Cyt b559 was significantly destabilized (converted to the IP form) in mutant PSII core complexes of Cyt b559 mutant strains (I14Aα, I14Sα, R18Sα, I27Aα, I27Tα, and F32Yβ; Guerrero et al., 2014). When the oxygen-evolving complex was inactive, the yield of dark-reduction of Cyt b559 was lower and the kinetics was slower in the R18Sα mutant than in wild-type cells. The results support the concept that the HP form of Cyt b559 may function as a PQH2 oxidase to keep the PQ pool oxidized and also as an electron reservoir for the cyclic electron flow within PSII when the donor-side of PSII is impaired (Guerrero et al., 2014).

Moreover, a previous spectroscopic study showed that different spectral forms of Car were oxidized in PSII samples containing different redox forms of Cyt b559 (Tracewell and Brudvig, 2008). The authors proposed that the quenching properties of PSII may be controlled by the redox form of Cyt b559 by modulating the different type of oxidized Car species (radical cation or neutral radical) formed in PSII. Future study could investigate the quenching properties of PSII in the wild type versus Cyt b559 mutant strains of cyanobacteria with different redox forms of Cyt b559 to validate this proposal.

**EFFECTS ON PHOTOSYNTHETIC LIGHT HARVESTING**

Recent mutant studies revealed a novel role of Cyt b559 in modulating photosynthetic light harvesting in PSII reaction centers. A spontaneously generated mutant from Synechocystis sp. PCC 6803 wild-type cells grown in BG-11 agar plates containing 5 mM Glu and 10 μM DCMU carried an Arg7 to Leu mutation on the alpha-subunit of Cyt b559 in PSII (Chiu et al., 2009). Results of 77-K fluorescence and room-temperature chlorophyll a fluorescence spectra indicated that the energy transfer from phycobilisomes to PSII reaction centers was partially inhibited or uncoupled in this mutant. In addition, the cytoplasmic side of Cyt b559 is located within the predicted contact sites in PSII for the APC core complex of the phycobilisome (Barber et al., 2003). The Arg7 to Leu mutation of Cyt b559 may alter the interaction between the APC core complex and PSII reaction centers, thereby reducing energy delivery from the antenna to the reaction center and protecting mutant cells against DCMU-induced photo-oxidative stress (Rutherford and Krieger-Liszkay, 2001).

Many cyanobacteria including Synechocystis sp. PCC 6803 have a novel blue-green light-induced NPQ mechanism to protect PSII reaction centers against photodamage under high-light stress (Kirilovsky and Kerfeld, 2012). Under high-light conditions, a soluble orange carotenoid protein is able to absorb blue–green light and undergoes photo-conversion into the active red form, which interacts with the APC core of the phycobilisome and dissipates excess excitation energy from the phycobilisome as heat. Interestingly, several Synechocystis sp. PCC 6803 mutant cells (e.g., R7La and R17β) with mutations on the cytoplasmic side of Cyt b559 in PSII showed significant inhibition of the effects of blue–green light-induced NPQ and apparent acceleration on its recovery (Chiu et al., 2013). These results are consistent with the proposal that the mutations on Cyt b559 may alter the interaction between the phycobilisome and PSII reaction centers, thereby affecting the regulation of photosynthetic light harvesting in Synechocystis sp. PCC 6803.

**CONCLUSION AND PERSPECTIVES**

Site-directed mutagenesis studies combined with spectroscopic and functional characterization have revealed multiple roles of Cyt b559 in the assembly and photoprotection of PSII reaction centers. The findings provide convincing evidence for the physiological role(s) of Cyt b559 in a photoprotective secondary electron transfer pathway within PSII reaction centers, as was suggested from earlier studies of isolated PSII complexes (reviews in Whitmarsh and Pakrasi, 1996; Stewart and Brudvig, 1998; Shinopoulos and Brudvig, 2012). In the near future, site-directed mutagenesis studies combined with advanced high-resolution protein crystallography and spectroscopic and functional analysis will provide further new insights (e.g., structure and function relationships for different redox forms of Cyt b559) and possibly the final proof of the molecular mechanisms of Cyt b559 in PSII.
