Measurement of $\mathcal{CP}$ Asymmetries and Branching Fractions in $B \to \pi \pi$ and $B \to K \pi$ decays.

The BABAR Collaboration

July 29, 2006

Abstract

We present preliminary measurements of the $\mathcal{CP}$ asymmetries and branching fractions for $B \to \pi \pi$ and $B \to K \pi$ decays. A total of 347 million $B\bar{B}$ events collected by the BABAR detector at the PEP-II asymmetric-energy $e^+e^-$ collider at SLAC are used for these results. We find

$$S_{\pi\pi} = -0.53 \pm 0.14 \pm 0.02$$
$$C_{\pi\pi} = -0.16 \pm 0.11 \pm 0.03$$
$$A_{K\pi} = -0.108 \pm 0.024 \pm 0.008$$
$$\mathcal{B}(B^0 \to \pi^0 \pi^0) = (1.48 \pm 0.26 \pm 0.12) \times 10^{-6}$$
$$\mathcal{B}(B^\pm \to \pi^\pm \pi^0) = (5.12 \pm 0.47 \pm 0.29) \times 10^{-6}$$
$$\mathcal{B}(B^\pm \to K^\pm \pi^0) = (13.3 \pm 0.56 \pm 0.64) \times 10^{-6}$$
$$C_{\pi^0\pi^0} = -0.33 \pm 0.36 \pm 0.08$$
$$A_{\pi^0\pi^0} = -0.019 \pm 0.088 \pm 0.014$$
$$A_{K^0\pi^0} = 0.016 \pm 0.041 \pm 0.012$$

The measured values of $S_{\pi\pi}$ and $C_{\pi\pi}$ imply that $\mathcal{CP}$ conservation in $B^0 \to \pi^+\pi^-$ decays is excluded at the 3.6 $\sigma$ level. From these results we present bounds on the CKM angle $\alpha$.

Submitted to the 33$^{rd}$ International Conference on High-Energy Physics, ICHEP 06, 26 July—2 August 2006, Moscow, Russia.

1 INTRODUCTION

CP-violating processes are incisive tests of the Cabibbo-Kabayashi-Maskawa (CKM) model of quark mixing [1]. Measurements with small theoretical uncertainties in the CKM model provide the most effective constraints on physics outside this model. The CKM Unitarity Triangle angle \( \alpha \equiv \arg \left( \frac{-V_{td}V_{tb}^*}{V_{ud}V_{ub}^*} \right) \) is measured through the interference of \( b \to u \) quark-level decays and \( B^0 \leftrightarrow \bar{B}^0 \) mixing. Multiple measurements of \( \alpha \), with different decays, further test the consistency of the CKM model.

The time-dependent asymmetry in \( B_0^+ \to \pi^+ \pi^− \) is proportional to \( \sin^2 \alpha \) in the limit that only one amplitude contributes to this decay. However, measurements of an unexpectedly large branching fraction for \( B_0^0 \to \pi^0 \pi^0 \) compared to that of \( B^± \to \pi^± \pi^0 \) and \( B^0 \to \pi^+ \pi^− \) [2] indicate that both \( b \to u \) (tree) and \( b \to d \) (penguin) amplitudes, with different weak phases, are present. Thus, the time-dependent asymmetry is modified to

\[
a(\Delta t) = \frac{\left| \bar{A}(\Delta t) \right|^2 - \left| A(\Delta t) \right|^2}{\left| A(\Delta t) \right|^2 + \left| \bar{A}(\Delta t) \right|^2} = S_{\pi \pi} \sin (\Delta m_d \Delta t) - C_{\pi \pi} \cos (\Delta m_d \Delta t)
\]

where \( \Delta t \) is the difference between the proper decay times and \( \Delta m_d \) is the B-meson mixing frequency. Both the total phase difference \( \Delta \alpha_{\pi \pi} \) and \( C_{\pi \pi} \) may differ from zero due to a penguin contribution to the decay amplitude \( A \).

The magnitude and relative phase of the penguin contribution to the asymmetry may be unraveled with an isospin relation between the three \( B \to \pi \pi \) decays [3]. The amplitudes \( A^{ij} \) for the \( B \to \pi^i \pi^j \) decays satisfy the relation

\[
A^{+0} = \frac{1}{\sqrt{2}} A^{+-} + A^{00},
\]

with a similar expression for the conjugate amplitudes. The shape of the corresponding isospin triangle is determined from measurements of the branching fraction and time-integrated CP asymmetry for each \( B \to \pi \pi \) decay. We define the direct CP asymmetry as

\[
C_{\pi^0 \pi^0} = \frac{|A^{00}|^2 - |A^{00}|^2}{|A^{00}|^2 + |A^{00}|^2}, \quad A_{\pi^0 \pi^0} = \frac{|A^{00}|^2 - |A^{00}|^2}{|A^{00}|^2 + |A^{00}|^2}.
\]

From the difference in shape of these triangles for \( B^0 \) and \( \bar{B}^0 \), \( \Delta \alpha_{\pi \pi} \) may be determined up to a four-fold ambiguity. No CP asymmetry is expected in the \( \Delta I = 3/2 \) decay \( B^± \to \pi^± \pi^0 \), where no penguin amplitudes are present.

The phenomenology of the \( B \to \pi \pi \) system has been studied in a variety of theoretical frameworks and models [4]. Predictions for the relative size and phase of the penguin contribution vary considerably, so more precise measurements will help to distinguish among different theoretical approaches and add to our understanding of hadronic B decays.

In addition to the unexpected pattern of decay rates in the \( B \to \pi \pi \) system mentioned above, the measured rates and direct CP-violating asymmetries in \( B \to K \pi \) decays [5, 6, 7] reveal puzzling features that could indicate significant contributions from electroweak (EW) penguins [8, 9].
Various methods have been proposed to isolate the Standard Model contribution to this process in order to test for signs of new physics. Sum rules derived from $U$-spin symmetry relate the rates and asymmetries for the decays $B^0$ or $B^+$ to $K^+\pi^-$, $K^+\pi^0$, $K^0\pi^0$, and $K^0\pi^+$ [10], while $SU(3)$ symmetry can be used to make predictions for the $K\pi$ system based on hadronic parameters extracted from the $\pi\pi$ system [8].

2 THE BaBar DETECTOR AND DATASET

The data used in this analysis were collected in 1999–2006 with the BaBar detector at the PEP-II asymmetric-energy $B$-meson factory at the Stanford Linear Accelerator Center. A total of 347 million $B\bar{B}$ pairs were used. The preliminary results presented here supersede the results in three prior publications [11]. Roughly 120 million more $B\bar{B}$ decays have been added, and a number of improvements have been introduced to the data analysis, effectively increasing the acceptance for the modes containing a neutral pion.

The BaBar detector is described in detail elsewhere [12]. Charged-particle (track) momenta are measured with a 5-layer double-sided silicon vertex tracker (SVT) and a 40-layer drift chamber (DCH) inside a 1.5-T superconducting solenoidal magnet. Neutral-cluster (photon) positions and energies are measured with an electromagnetic calorimeter (EMC) consisting of 6580 CsI(Tl) crystals. The photon energy resolution is $\sigma_E/E = \{2.3/E(\text{GeV})^{1/4} + 1.9\} \%$, and the angular resolution from the interaction point is $\sigma_\theta = 3.9^\circ/\sqrt{E(\text{GeV})}$. Charged hadrons are identified with a detector of internally reflected Cherenkov light (DIRC) and ionization measurements in the tracking detectors. The average $K-\pi$ separation in the DIRC varies from 12$\sigma$ at a laboratory momentum of 1.5 $\text{GeV}/c$ to 2$\sigma$ at 4.5 $\text{GeV}/c$.

3 ANALYSIS METHOD

Many elements of the $B \to \pi\pi$ measurements are common to the three groups of decay modes $B^0 \to h^+h^-(h = \pi$ or $K)$, $B^0 \to \pi^0\pi^0$, and $B^\pm \to h^\pm\pi^0$. $B$ candidates ($B_{\text{rec}}$) are formed by combining two particles, either tracks or $\pi^0$ candidates.

3.1 Track and Cluster Selection

For the $B^\pm \to h^\pm\pi^0$ and the $B^0 \to h^+h^-$ samples, we require that each track have an associated Cherenkov angle ($\theta_C$) measured with more than five signal photons detected in the DIRC, where the value of $\theta_C$ must agree with either the pion or kaon particle hypothesis to within 4$\sigma$. The last requirement efficiently removes events containing high-momentum protons. Electrons are removed based on energy-loss measurements in the SVT and DCH, and on a comparison of the track momentum and the associated energy deposited in the EMC.

The $\pi^0$ candidates are formed from two EMC clusters, one EMC cluster containing two nearby photons (merged $\pi^0$), or one EMC cluster and two tracks from a photon conversion to an $e^+e^-$ pair inside the detector. Previous BaBar results for $B^0 \to \pi^0\pi^0$ and $B^\pm \to h^\pm\pi^0$ only included $\pi^0$ from two EMC clusters; the addition of merged $\pi^0$ and converted photons increases the $\pi^0$ efficiency by 10%. Clusters are required to have a transverse energy deposit consistent with a photon, and to have an energy $E_\gamma > 0.03$ GeV. To reduce the background from random photon combinations, the angle $\theta_\gamma$ between the photon momentum vector in the $\pi^0$ rest frame and the $\pi^0$ momentum
vector in the laboratory frame is required to satisfy $|\cos \theta_v| < 0.95$. The $\pi^0$ candidates are fitted kinematically with their mass constrained to the nominal $\pi^0$ mass.

Photon conversions are selected from pairs of oppositely charged tracks with invariant mass less than 30 MeV/$c^2$ and whose momentum vector points to the beamspot. The conversion point is required to lie inside the detector material. Photons from conversions are combined with photons from single EMC clusters to form $\pi^0$ candidates.

Single EMC clusters containing two photons are selected with the transverse second moment,

$$S = \sum_i E_i \times (\Delta \alpha_i)^2 / E_i,$$

where $E_i$ is energy in each CsI(Tl) crystal and $\Delta \alpha_i$ is the angle between the cluster centroid and the crystal. The second moment is used to distinguish merged $\pi^0$ candidates from both single photons and neutral hadrons.

### 3.2 Event Selection

Two kinematic variables are used to separate $B$ decays from the large $e^+e^- \rightarrow q\bar{q}$ ($q = u, d, s, c$) background: the beam-energy–substituted mass $m_{\text{ES}} = \sqrt{(s/2 + p_i \cdot p_B)^2 / E_i^2 - p_B^2}$, where $s$ is the total $e^+e^-$ center-of-mass (CM) energy, $(E_i, p_i)$ is the four-momentum of the initial $e^+e^-$ system and $p_B$ is the $B$-candidate momentum, both measured in the laboratory frame, and $\Delta E = E_B - \sqrt{s}/2$, where $E_B$ is the $B$-candidate energy in the CM frame.

Two additional quantities take advantage of the event topology to further separate $B$ decays from $q\bar{q}$ background. The cosine of the angle $\theta_s$ between the sphericity axes of the $B$ candidate’s decay products and that of the remaining tracks and clusters in the event, in the CM frame, is peaked at ±1.0 for jet-like $q\bar{q}$ events, but has a flat distribution for $B$ decays. We require $|\cos \theta_v| < 0.7$ (0.8) for $B^0 \rightarrow \pi^0\pi^0$ ($B^+ \rightarrow h^+\pi^0$ and $B^0 \rightarrow h^+h^-$). For just the $B^0 \rightarrow h^+h^-$ sample, we further require that the second Fox–Wolfram moment satisfy $R_2 < 0.7$ to remove a small remaining background from $\tau$-pair events. To improve the discrimination against $q\bar{q}$ events, a Fisher discriminant $F$ is formed from the sums $\sum_i p_i$ and $\sum_i p_i \cos^2 \theta_i$, where $p_i$ is the momentum and $\theta_i$ is the angle with respect to the thrust axis of the $B$ candidate, both in the CM frame, of all tracks and clusters not used to reconstruct the $B$ meson.

The number of $B$ decays and the corrisponding $CP$ asymmetries are determined in extended unbinned maximum likelihood (ML) fits to the variables $m_{\text{ES}}, \Delta E,$ and $F$, plus additional information as described below. The likelihood is given by the expression

$$\mathcal{L} = \exp \left( -\sum_i^M n_i \right) \prod_j^N \left[ \sum_i^M n_i \mathcal{P}(\tilde{x}_j; \tilde{\alpha}_i) \right],$$

where the product is over the number of events $N$, the sums are over the event categories $M$, $n_i$ is the coefficient for each category as described below, and the probability density function (PDF) $\mathcal{P}$ describes the distribution of the variables $\tilde{x}$ in terms of parameters $\tilde{\alpha}$.

### 3.3 $B^0 \rightarrow \pi^+\pi^-$ and $B^0 \rightarrow K^+\pi^-$

The time-dependent $CP$ asymmetry measurement in $B^0 \rightarrow \pi^+\pi^-$ also uses $B$-flavor, decay-time, and particle-identification information to separate $B^0 \rightarrow \pi^+\pi^-$ and $B^0 \rightarrow K^+\pi^-$ decays and measure their $CP$ asymmetries.

The variables $m_{\text{ES}}$ and $\Delta E$ are calculated assuming that both tracks are charged pions. $B \rightarrow \pi\pi$ events are described by a Gaussian distribution for both $m_{\text{ES}}$ and $\Delta E$, with resolutions of 2.5 MeV/$c^2$ and 28 MeV, respectively. For each kaon in the final state, the $\Delta E$ peak position is shifted from
PDF is a double Gaussian for the background and an asymmetric Gaussian for the signal. All
us to separate product of the fraction of events in each tagging category, taken from
yield. The background PDFs are a threshold function for $m_n$ correlation between
pions. The difference between the measured and expected value of likelihood fit.

$3.4 \ B^0 \rightarrow \pi^0\pi^0$

$B^0 \rightarrow \pi^0\pi^0$ events are identified with an ML fit to the variables $m_{ES}$, $\Delta E$, and $F$. For $B^0 \rightarrow \pi^0\pi^0$, we require $m_{ES} > 5.20 \text{ GeV}/c^2$ and $|\Delta E| < 0.150 \text{ GeV}$. Tails in the EMC response produce a correlation between $m_{ES}$ and $\Delta E$, so a two-dimensional PDF, derived from Monte Carlo (MC)
decay modes with the estimated number of events provided in parentheses. All $B\bar{B}$ and $F$ for events), Table 2. Distributions of $B_\pi$ the use of the Cherenkov angle for kaons and pions is identical to that in $B_\pi$. We require $B$ candidates to satisfy $|\Delta E| < 0.11$ GeV and $-0.15 < \Delta E < 0.15$ GeV. The tighter requirement on $\Delta E$ serves to remove $B$-decay backgrounds. The treatment of $\Delta E$ and the use of the Cherenkov angle for kaons and pions is identical to that in $B^0 \rightarrow \pi^+\pi^-$. The $F$ distribution is also described with a step function, with parameters taken from MC simulation. The $q\bar{q}$ background PDFs are a threshold function for $q\bar{q}$, and $\Delta E$ and with a step function for $F$, all taken from MC simulation. The time-integrated $CP$ asymmetry is measured by the $B$-flavor tagging described previously. The fraction of events in each tagging category is also constrained to the fractions determined from MC simulation. The PDF coefficient for the $B^0 \rightarrow \pi^0\pi^0$ signal is given by the expression

$$n_{k00} = \frac{1}{2} f_k N_{k00} \left( 1 - s_j (1 - 2\chi)(1 - 2w_k) C_{k00} \right),$$

where $f_k$ is the fraction of events in tagging category $k$, $N_{k00}$ is the number of $B$ decays, $\chi = 0.184 \pm 0.004$ [14] is the time-integrated mixing probability, and $s_j = +1(-1)$ when the $B_{\text{tag}}$ is a $B^0 (B^0)$.  

### 3.5 $B^\pm \rightarrow \pi^\pm\pi^0$ and $B^\pm \rightarrow K^\pm\pi^0$

$B^\pm \rightarrow \pi^\pm\pi^0$ and $B^\pm \rightarrow K^\pm\pi^0$ events are identified in an ML fit to the variables $m_{ES}$, $\Delta E$, $F$, and $\theta_C$. We require $B$ candidates to satisfy $m_{ES} > 5.22$ GeV/c$^2$ and $-0.11 < \Delta E < 0.15$ GeV. The $q\bar{q}$ background PDF parameters are floating in the ML fit. The decay modes are summarized in Table 2. Results from the ML fits for the $B^0 \rightarrow \pi^0\pi^0$ and $B^\pm \rightarrow h^\pm\pi^0$ decay modes are summarized in Table 2. Distributions of $m_{ES}$, $\Delta E$, and $F$ for $B^0 \rightarrow \pi^0\pi^0$ are in Fig. 1, where a signal-enhanced subset of the data is shown. The $B^\pm \rightarrow h^\pm\pi^0$ data are shown in Fig. 2. With a large signal in both decay modes, we show weighted and background-subtracted plots [15] for the $B^\pm \rightarrow \pi^0\pi^0$ and $B^\pm \rightarrow K^\pm\pi^0$ signal. The same technique is used to display the $q\bar{q}$ background as well.

### 4 RESULTS AND SYSTEMATIC UNCERTAINTIES

Results from the ML fits for the $B^0 \rightarrow \pi^0\pi^0$ and $B^\pm \rightarrow h^\pm\pi^0$ decay modes are summarized in Table 2. Distributions of $m_{ES}$, $\Delta E$, and $F$ for $B^0 \rightarrow \pi^0\pi^0$ are in Fig. 1, where a signal-enhanced subset of the data is shown. The $B^\pm \rightarrow h^\pm\pi^0$ data are shown in Fig. 2. With a large signal in both decay modes, we show weighted and background-subtracted plots [15] for the $B^\pm \rightarrow \pi^0\pi^0$ and $B^\pm \rightarrow K^\pm\pi^0$ signal. The same technique is used to display the $q\bar{q}$ background as well.
The uncertainty in the efficiency for the \( B^0 \to \pi^0\pi^0 \) decay mode is dominated by a 3% systematic uncertainty per \( \pi^0 \), estimated from a study of \( \tau \to \pi^0\pi^0\nu \) decays. There is an additional 3.6% uncertainty from our knowledge of the EMC resolution function, based on a study of the resolution of the \( \pi^0 \) mass and the energy of the photon in \( e^+e^- \to \mu^+\mu^-\gamma \) events. Systematic uncertainties involving the ML fit are evaluated by varying the PDF parameters and refitting the data. The changes in the \( m_{ES} \) and \( \Delta E \) signal PDFs are taken from the difference in these quantities in the \( B^\pm \to h^\pm\pi^0 \) sample between data and MC. The change in the result is taken as the systematic error. All sources of systematic error for \( B^0 \to \pi^0\pi^0 \) are listed in Table 3.

The largest uncertainties in the \( B^\pm \to h^\pm\pi^0 \) decays arise from uncertainty in the \( m_{ES} \) and \( \Delta E \) PDFs, our knowledge of the signal \( F \) distribution evaluated from a sample of \( B^\pm \) decays, and the 3\% \( \pi^0 \) efficiency uncertainty. The size of a small bias in the ML fit is included as a systematic error. The dominant uncertainty on the direct CP asymmetries are taken from the size and error in the asymmetry fit in the \( q\bar{q} \) background and the effect of CP violation in the \( B \) backgrounds. The uncertainties in \( B^\pm \to h^\pm\pi^0 \) are summarized in Table 4.

All results for the \( B^0 \to h^+h^- \) decay modes are listed in Table 5. The correlation coefficient between \( S_{\pi\pi} \) and \( C_{\pi\pi} \) is found to be \(-0.082\). The data distributions of \( m_{ES} \), \( \Delta E \), and \( F \) for \( B^0 \to h^+h^- \) decays are shown in Fig. 3 for signal and Fig. 4 for background with the event-weighting technique. The direct CP asymmetry in \( B^0 \to K^+\pi^- \) is apparent in the distribution of \( \Delta E \) for \( B^0 \) and \( \bar{B}^0 \) decays, shown in Fig. 5. We show the distributions of \( \Delta t \) for signal and background decays in Fig. 6. In Fig. 7, we show the distribution of \( \Delta t \) separately for \( B^0 \to \pi^+\pi^- \) events tagged as \( B^0 \) or \( \bar{B}^0 \), and the asymmetry \( a(\Delta t) \). The central values and errors for \( S_{\pi\pi} \) and \( C_{\pi\pi} \) are shown in Fig. 8, along with confidence-level contours. Our measurement excludes the absence of CP violation (\( S_{\pi\pi} = 0, C_{\pi\pi} = 0 \)) at a confidence level of 0.99970, or 3.6 \( \sigma \).

Systematic uncertainties for the CP asymmetries \( A_{K\pi}, S_{\pi\pi}, \) and \( C_{\pi\pi} \) are listed in Table 6. For the asymmetry in the \( K^+\pi^- \) mode, we find a background asymmetry of \(-0.0042 \pm 0.0064\), which is consistent with zero. We therefore take the sum in quadrature of the central value of the background asymmetry and its statistical uncertainty as the systematic uncertainty on the signal \( A_{K\pi} \) to account for possible charge-dependent detector and analysis bias. To further check for biases in the fitting technique, we perform a large number of pseudo-experiments where the signal events are randomly sampled from simulated MC events, and the background is generated directly from the PDFs. We find a bias in \( A_{K\pi} \) of 0.002 and include this in the systematic uncertainty. The biases on \( S_{\pi\pi} \) and \( C_{\pi\pi} \) in this study are consistent with zero, so we take the sum in quadrature of the central value and its uncertainty as the systematic error due to potential bias in the fitter. The remaining systematic effects for \( S_{\pi\pi} \) and \( C_{\pi\pi} \) are dominated by uncertainties in the parameterization of \( B \)-flavor tagging and vertexing, and (for \( C_{\pi\pi} \)) in the effect of CP violation on the tag side.
5 CONCLUSIONS

The branching-fraction and $CP$-asymmetry results described in this paper are:

\[
S_{\pi\pi} = -0.53 \pm 0.14 \pm 0.02 \\
C_{\pi\pi} = -0.16 \pm 0.11 \pm 0.03 \\
A_{K\pi} = -0.108 \pm 0.024 \pm 0.008 \\
B(B^0 \to \pi^0 \pi^0) = (1.48 \pm 0.26 \pm 0.12) \times 10^{-6} \\
B(B^\pm \to \pi^\pm \pi^0) = (5.12 \pm 0.47 \pm 0.29) \times 10^{-6} \\
B(B^\pm \to K^\pm \pi^0) = (13.3 \pm 0.56 \pm 0.64) \times 10^{-6} \\
C_{\pi^0\pi^0} = -0.33 \pm 0.36 \pm 0.08 \\
A_{\pi^0\pi^0} = -0.019 \pm 0.088 \pm 0.014 \\
A_{K\pi^0} = 0.016 \pm 0.041 \pm 0.012.
\]

Combining these with a branching fraction $B(B^0 \to \pi^+ \pi^-) = (5.8 \pm 0.4 \pm 0.3) \times 10^{-6}$, also measured by BABAR [16], we may evaluate the constraints on both the penguin contribution to $\alpha$ and on the CKM angle $\alpha$ itself. Constraints are evaluated by scanning the parameters of interest, $|\Delta \alpha_{\pi\pi}| = |\alpha - \alpha_{\text{eff}}|$ and $\alpha$, and then calculating the $\chi^2$ for the five amplitudes ($A^{+0}$, $A^{-+}$, $A^{00}$, $A^{+-}$, $A^{00}$) given our measurements and the isospin-triangle relations [17]. The $\chi^2$ is converted to a confidence level (C.L.) as shown in Fig. 9. The upper bound on $|\Delta \alpha_{\pi\pi}|$ is $41^\circ$ at the 90% C.L. Somewhat more restrictive new constraints on $\alpha$ are found from measurements of $B \to \rho \rho$ and $B \to \rho \pi$ decays [18].

We have also presented updated preliminary measurements of the branching fraction for $K^{+} \pi^{0}$, and the charge asymmetries in $K^{+}\pi^{-}$ and $K^{+}\pi^{0}$. Ignoring color-suppressed tree amplitudes, the charge asymmetries in $K^{+}\pi^{-}$ and $K^{+}\pi^{0}$ should be equal (see Gronau and Rosner in Ref. [10]), which has not been supported by recent data [5]. The values of $A_{K\pi}$ and $A_{K\pi^0}$ reported here are separated by over two standard deviations. These results could indicate a large color-suppressed amplitude, an enhanced electroweak penguin, or possibly new-physics effects [19].

6 ACKNOWLEDGMENTS

We are grateful for the extraordinary contributions of our PEP-II colleagues in achieving the excellent luminosity and machine conditions that have made this work possible. The success of this project also relies critically on the expertise and dedication of the computing organizations that support BABAR. The collaborating institutions wish to thank SLAC for its support and the kind hospitality extended to them. This work is supported by the US Department of Energy and National Science Foundation, the Natural Sciences and Engineering Research Council (Canada), Institute of High Energy Physics (China), the Commissariat à l’Energie Atomique and Institut National de Physique Nucléaire et de Physique des Particules (France), the Bundesministerium für Bildung und Forschung and Deutsche Forschungsgemeinschaft (Germany), the Istituto Nazionale di Fisica Nucleare (Italy), the Foundation for Fundamental Research on Matter (The Netherlands), the Research Council of Norway, the Ministry of Science and Technology of the Russian Federation, Ministerio de Educación y Ciencia (Spain), and the Particle Physics and Astronomy Research Council (United Kingdom). Individuals have received support from the Marie-Curie IEF program (European Union) and the A. P. Sloan Foundation.

Table 2: The results for the $B^0 \rightarrow \pi^0\pi^0$ and $B^\pm \rightarrow h^\pm\pi^0$ decay modes are summarized. For each mode, the number of signal events $N_S$, total detection efficiency $\epsilon$, branching fraction $B$, and $CP$ asymmetry are given. Errors on $B$ and the asymmetries are statistical and systematic, respectively, while errors for $N_S$ are statistical and those for $\epsilon$ are purely systematic.

| Mode          | $N_S$   | $\epsilon$ (%) | $B(10^{-6})$ | Asymmetry       |
|---------------|---------|-----------------|--------------|-----------------|
| $B^0 \rightarrow \pi^0\pi^0$ | 140 ± 25 | 27.1 ± 1.7      | 1.48 ± 0.26 ± 0.12 | $C_{\pi^0\pi^0} = -0.33 ± 0.36 ± 0.08$ |
| $B^\pm \rightarrow \pi^\pm\pi^0$ | 572 ± 53 | 32.1 ± 1.8      | 5.12 ± 0.47 ± 0.29 | $A_{\pi^0} = -0.019 ± 0.088 ± 0.014$ |
| $B^\pm \rightarrow K^\pm\pi^0$ | 1239 ± 52 | 26.8 ± 1.3      | 13.3 ± 0.56 ± 0.64 | $A_{K\pi^0} = 0.016 ± 0.041 ± 0.012$ |

Table 3: Systematic uncertainties in the determination of the $B^0 \rightarrow \pi^0\pi^0$ branching fraction (left) as a percentage change, and the $C_{\pi^0\pi^0}$ asymmetry (right) as an absolute change.

| Source               | $\Delta B(\pi^0\pi^0)$ (%) | Source             | $\Delta (C_{\pi^0\pi^0})$ |
|----------------------|------------------------------|--------------------|----------------------------|

| Total                | 8.2%                         |                    |                            |
Figure 1: The distributions of (a) $m_{ES}$, (b) $\Delta E$, and (c) Fisher discriminant $F$ for $B^0 \rightarrow \pi^0 \pi^0$ candidates that satisfy an optimized requirement on the signal probability, based on all variables except the one being plotted. The projections contain 27%, 30% and 68% of the signal, 20%, 21% and 23% of the $\rho\pi^0$ background, and 2.8%, 0.047% and 4.8% of the continuum background, for $m_{ES}$, $\Delta E$, and $F$, respectively. The PDF projections are shown as a dashed line for $q\bar{q}$ background, a dotted line for $B^\pm \rightarrow \rho^\pm \pi^0$ and $B^0 \rightarrow K^0\pi^0$, and a dashed-dotted line for $B^0 \rightarrow \pi^0\pi^0$ signal. The solid line shows the sum of all PDF projections. The PDF projections are scaled by the expected fraction of events passing the probability-ratio requirement. Also shown (d) is the ratio of the PDF for signal to the PDF for signal plus background comparing data (points) to the components of the PDF model.
Figure 2: The distributions and PDF projections of $m_{ES}$ (top), $\Delta E$ (middle), and Fisher discriminant $F$ (bottom), for $B^\pm \rightarrow \pi^\pm \pi^0$ (left) and $B^\pm \rightarrow K^\pm \pi^0$ (right) candidates. The main plots show the signal data (points) and PDF (line) after event weighting and background subtraction with the method described in [15]; the method uses all variables except the one being plotted. The insets show the corresponding distributions for background.
Table 4: Dominant systematic uncertainties for $B^\pm \to \pi^\pm \pi^0$ and $B^\pm \to K^\pm \pi^0$, as percentage changes in the branching fractions $\mathcal{B}$ (left), and absolute changes in the asymmetries $A_{\pi^\pm \pi^0}, A_{K^\pm \pi^0}$ (right). $\mathcal{A} = (N_{B^0} - N_{\overline{B}^0}) / (N_{B^0} + N_{\overline{B}^0})$.

Figure 3: The background-subtracted distributions of $m_{ES}$ (top), $\Delta E$ (middle), and Fisher discriminant $\mathcal{F}$ (bottom) for signal $B^0 \rightarrow \pi^+\pi^-$ (left) and $B^0 \rightarrow K^+\pi^-$ (right) candidates in the data. The curves represent the PDFs used in the fit.
Figure 4: The signal-subtracted distributions of $m_{ES}$ (left), $\Delta E$ (middle), and Fisher discriminant $F$ (right) for all background $h^+h'^-$ candidates in the data. The curves represent the PDFs used in the fit.

Figure 5: The background-subtracted distribution of $\Delta E$ for signal $K^\pm\pi^\mp$ events, comparing $B^0$ (solid) and $\bar{B}^0$ decays (dashed).

Figure 6: The background-subtracted distributions of $\Delta t$ for signal $\pi^+\pi^-$ (left), $K^\pm\pi^\mp$ (middle), and the signal-subtracted $\Delta t$ distribution for background candidates in the data (right). The curves represent the PDFs used in the fit.
Figure 7: The background-subtracted distributions of $\Delta t$ for signal $\pi^+\pi^-$ events tagged as $B^0$ (top) or $\bar{B}^0$ (middle), and the asymmetry, defined as $A = (N_{B^0} - N_{\bar{B}^0}) / (N_{B^0} + N_{\bar{B}^0})$ (bottom). The curves represent the PDFs used in the fit.
Figure 8: Central value and errors for $S_{\pi\pi}$ and $C_{\pi\pi}$ and confidence-level (C.L.) contours. The measured value is $3.6 \sigma$ from the point of no $CP$ violation ($S_{\pi\pi} = 0$, $C_{\pi\pi} = 0$), converting from the C.L. to the units of “two-sided” Gaussian significance.
Figure 9: Constraint on the angle $\Delta \alpha_{\pi\pi} = \alpha - \alpha_{\text{eff}}$ (top), expressed as one minus the confidence level (C.L.) as a function of $|\Delta \alpha_{\pi\pi}|$. We find an upper bound on $|\Delta \alpha_{\pi\pi}|$ of 41° at the 90% C.L. Constraint on the CKM angle $\alpha$ (bottom) expressed as $1 - \text{C.L.}$ The eight peaks correspond to an eight-fold ambiguity in the extraction of $\alpha$; four solutions are from the value and sign of $\Delta \alpha_{\pi\pi}$, which is doubled due to the trigonometric reflections between $\alpha_{\text{eff}}$ and $\pi/2 - \alpha_{\text{eff}}$. Only the isospin-triangle relations and the expressions in Eqn. 1 are used in this constraint. The solution at exactly $\alpha = 0$ is excluded at $1 - \text{C.L.} = 4.4 \times 10^{-5}$, not shown in the plot, corresponding to the exclusion of $S_{\pi\pi} = 0$, $C_{\pi\pi} = 0$ at 3.6 $\sigma$. Some of the solutions, and the region around $\alpha = 0$, can be disfavored by other physics information.
