A Heuristic Proof Procedure for First-Order Logic

Keehang Kwon

Abstract
Inspired by the efficient proof procedures discussed in Computability logic [1, 4, 5], we describe a heuristic proof procedure for first-order logic. This is a variant of Gentzen sequent system and has the following features: (a) it views sequents as games between the machine and the environment, and (b) it views proofs as a winning strategy of the machine.

From this game-based viewpoint, a powerful heuristic can be extracted and a fair degree of determinism in proof search can be obtained. This article proposes a new deductive system LKg with respect to first-order logic and proves its soundness and completeness.

Keywords: Proof procedures; Heuristics; Game semantics; Classical logics

1 Introduction

The Gentzen sequent system LK plays a key role in modern theorem proving. Unfortunately, the LK system and its variants such as focused LK (as well as resolution and tableaux (see [6] for discussions)) are typically based on blind search and, therefore, does not provide the best strategy if we want a short proof.

In this paper, inspired by the seminal work of [1], we present a variant of LK, called LKg (g for game), which yields a proof in normal form with the following features:

1. All the quantifier inferences are processed first. This is achieved via deep inference.
2. If there are several quantifiers to resolve in the sequent, we apply to sequents a technique called stability analysis, a powerful heuristic technique which greatly cuts down the search space for finding a proof.

In essence, LKg is a game-viewed proof which captures game-playing nature in proof search. It views

1. sequents as games between the machine and the environment,
2. proofs as a winning strategy of the machine, and
3. $\forall xF$ as the env’s move and $\exists xF$ as the machine’s move.

At each stage, we construct a proof by the following rules:

1. If the sequent is stable, then it means that the machine is the current winner. In this case, it requests the user to make a move.
2. If the sequent is instable, then it means that the environment is the current winner. In this case, the machine makes a move.

In this way, a fair (probably maximum) degree of determinism can be obtained from the LKg proof system.

In this paper we present the proof procedure for first-order classical logic. The remainder of this paper is structured as follows. We describe LKg in the next section. In Section 3, we present some examples of derivations. In Section 4, we prove the soundness and completeness of LKg. Section 5 concludes the paper.
2 The logic LKg

The formulas are the standard first-order classical formulas, with the features that (a) $\top, \bot$ are added, and
(b) $\neg$ is only allowed to be applied to atomic formulas. Thus we assume that formulas are in negation normal
form.

The deductive system LKg below axiomatizes the set of valid formulas. LKg is a one-sided sequent calculus system, where a sequent is a multiset of formulas. Our presentation closely follows the one in [1].

First, we need to define some terminology.

1. A surface occurrence of a subformula is an occurrence that is not in the scope of any quantifiers ($\forall$ and/or $\exists$).

2. A sequent is propositional iff all of its formulas are so.

3. The propositionalization $\|F\|$ of a formula $F$ is the result of replacing in $F$ all $\exists$-subformulas by $\bot$, and all $\forall$-subformulas by $\top$. The propositionalization $\|F_1, \ldots, F_n\|$ of a sequent $F_1, \ldots, F_n$ is the propositional formula $\|F_1\| \lor \ldots \lor \|F_n\|$.

4. A sequent is said to be stable iff its propositionalization is classically valid; otherwise it is unstable.

5. The notation $F[E]$ represents a formula $F$ together with some surface occurrence of a subformula $E$.

THE RULES OF LKg

LKg has the five rules listed below, with the following additional conditions:

1. $X$:stable means that $X$ must meet the condition that it is stable. Similarly for $X$:unstable.

2. $\Gamma$ is a multiset of formulas and $F$ is a formula.

3. In $\exists$-Choose, $t$ is a closed term, and $H(t)$ is the result of replacing by $t$ all free occurrences of $x$ in $H(x)$.

\[
\text{Fail}\\
\frac{\bot}{X:\text{unstable}} (X \text{ has no surface occurrences of } \exists x H(x))
\]

\[
\exists\text{-Choose}\\
\frac{\Gamma, F[H(t)]}{\Gamma, F[\exists x H(x)]:\text{unstable}}
\]

\[
\text{Replicate}\\
\frac{\Gamma, F[\exists x H(x)], F[\exists x H(x)]}{\Gamma, F[\exists x H(x)]:\text{unstable}}
\]

\[
\text{Succ}\\
\frac{\top}{X:\text{stable}} (X \text{ has no surface occurrences of } \forall x H(x))
\]
∀-Choose

\[ \Gamma, F[H(\alpha)] \]

\[ \Gamma, F[\forall x H(x)]: \text{stable} \]

In the above, the “Replicate” rule is an optimized version of what is known as Contraction, where contraction occurs only when there is a surface occurrence of \( \exists x H(x) \).

A \textbf{LKg-proof} of a sequent \( X \) is a sequence \( X_1, \ldots, X_n \) of sequents, with \( X_n = X, X_1 = \top \) such that, each \( X_i \) follows by one of the rules of LKg from \( X_{i-1} \).

3 Examples

Below we describe some examples.

\textbf{Example 3.1} The formula \( \forall x \exists y (p(x) \rightarrow p(y)) \) is provable in LKg as follows:

1. \( p(\alpha) \rightarrow p(\alpha) \) Succ
2. \( \exists y(p(\alpha) \rightarrow p(y)) \) \( \exists \text{-Choose} \)
3. \( \forall x \exists y(p(x) \rightarrow p(y)) \) \( \forall \text{-Choose} \)

\textbf{Example 3.2} The formula \( \exists y \forall x (p(x) \rightarrow p(y)) \) is provable in LKg as follows:

1. \( (p(\alpha_1) \rightarrow p(\alpha)), (p(\alpha_2) \rightarrow p(\alpha_1)) \) Succ
2. \( (p(\alpha_1) \rightarrow p(\alpha)), \forall x(p(x) \rightarrow p(\alpha_1)) \) \( \forall \text{-Choose} \)
3. \( (p(\alpha_1) \rightarrow p(\alpha)), \exists y\forall x(p(x) \rightarrow p(y)) \) \( \exists \text{-Choose} \)
4. \( \forall x(p(x) \rightarrow p(\alpha)), \exists y\forall x(p(x) \rightarrow p(y)) \) \( \forall \text{-Choose} \)
5. \( \exists y\forall x(p(x) \rightarrow p(y)), \exists y\forall x(p(x) \rightarrow p(y)) \) \( \exists \text{-Choose} \)
6. \( \exists y\forall x(p(x) \rightarrow p(y)) \) Replicate

On the other hand, the formula \((\exists x p(x) \rightarrow \forall y p(y))\) which is invalid can be seen to be unprovable. This can be derived only by two \( \forall \text{-Choose} \) rules and then the premise should be of the form \( \neg p(\alpha_1), p(\alpha_2) \) for some new constants \( \alpha_1, \alpha_2 \). The latter is not classically valid.

4 The soundness and completeness of LKg

We now present the soundness and completeness of LKg.

\textbf{Theorem 4.1} 1. If LKg terminates with success for \( X \), then \( X \) is valid.
2. If LKg terminates with failure for \( X \), then \( X \) is invalid.
3. If LKg does not terminate for \( X \), then \( X \) is invalid.

\textbf{Proof.} Consider an arbitrary sequent \( X \).

\textit{Soundness:} Induction on the length of derivations.

\textit{Case 1:} \( X \) is derived from \( Y \) by \( \exists \text{-Choose} \). By the induction hypothesis, \( Y \) is valid, which implies that \( X \) is valid.

\textit{Case 2:} \( X \) is derived from \( Y \) by Replicate. By the induction hypothesis, \( Y \) is valid. Then, it is easy to see that \( X \) is valid.

\textit{Case 3:} \( X \) is derived from \( Y \) by Succ.
In this case, we know that there is no surface occurrences of $\forall x \exists H(x)$ in $X$ and $\|X\|$ is classically valid. It is then easy to see that, reversing the propositionalization of $\|X\|$ (replacing $\bot$ by any formula of the form $F[\exists x H(x)]$) preserves validity. For example, if $X$ is $p(a) \rightarrow p(a), \exists q(x)$, then $\|X\|$ is valid and $X$ is valid as well.

Case 4: $X$ is derived from $Y$ by $\forall$-Choose.

Thus, there is an occurrence of $\forall x H(x)$ in $X$. The machine makes a move by picking up some fresh constant $c$ not occurring in $X$. Then, by the induction hypothesis, the premise is valid. Now consider any interpretation $I$ that makes the premise true. Then it is easy to see that the conclusion is true in $I$. It is commonly known as “generalization on constants”.

Completeness: Assume LKg terminates with failure.

We proceed by induction on the length of derivations.

If $X$ is stable, then there should be a LKg-unprovable sequent $Y$ with the following condition.

Case 1: $\forall$-Choose: $X$ has the form $\Gamma, F[\forall x G(x)]$, and $Y$ is $\Gamma, F[G(\alpha)]$, where $\alpha$ is a new constant not occurring in $X$. In this case, $Y$ is a LKg-unprovable sequent, for otherwise $X$ is LKg-provable. By the induction hypothesis, $Y$ is not true in some interpretation $I$. Then it is easy to see that $X$ is not true in $I$. Therefore $X$ is not valid.

Next, we consider the cases when $X$ is not stable. Then there are three cases to consider.

Case 2.1: Fail: In this case, there is no surface occurrence of $\exists x G(x)$ and the algorithm terminates with failure. As $X$ is not stable, $\|X\|$ is not classically valid. If we reverse the propositionalization of $\|X\|$ by replacing $\top$ by any formula with some surface occurrence of $\forall G(x)$, we observe that invalidity is preserved. Therefore, $X$ is not valid.

Case 2.2: $\exists$-Choose: In this case, $X$ has the form $\Gamma, F[\exists x G(x)]$, and $Y(t)$ is $\Gamma, F[G(t)]$, where $t$ is a closed term. In this case, $Y(t)$ is a LKg-unprovable sequent for any $t$, for otherwise $X$ is LKg-provable. By the induction hypothesis, none of $Y(t)$ is valid and thus none of $Y(t)$ is not true in some interpretation $I$. Then it is easy to see that $X$ is not true in $I$. Therefore $X$ is not valid.

Case 2.3: Replicate: In this case, $X$ has the form $\Gamma, F[\exists x G(x)]$, and $Y$ is $\Gamma, F[\exists x G(x)], F[\exists x G(x)]$. In this case, $Y$ is a LKg-unprovable sequent, for otherwise $X$ is LKg-provable. By the induction hypothesis, $Y$ is not valid and is not true in some interpretation $I$. Then it is easy to see that $X$ is not true in $I$. Therefore $X$ is not valid.

Now assume LKg is not terminating, because Replicate occurs infinitely many times. We prove this by contradiction.

Assume that $X$ is valid but unprovable. Let $Z$ be an infinite multiset of propositional formulas obtained by applying infinite numbers of Replicate, together with $\exists$-Choose and $\forall$-Choose rules. Then it is easy to see that $Z$ remains still valid but unprovable. By the compactness theorem on propositional logic, there is a finite subset $Z'$ of $Z$, which is a valid sequent. Then there must be a step $t$ in the procedure such that, after $t$, $Z'$ is derived. Then it is easy to see that $Z'$ remains LKg-unprovable. However, as $Z'$ is valid, it must be provable by Succ. This is a contradiction and, therefore, $X$ is not valid.

5 Some Optimizations

Although LKg performs well for valid sequents, it performs poorly for invalid sequents. For example, it does not even terminate for the invalid sequent $p(a), p(b) \land \exists x q(x)$.

For this reason, what we need is a good heuristic for determining, in a simple yet effective way, whether a sequent is invalid. In this section, we employ a simple heuristic called maximum propositionalization which replaces in a sequent $X$ all $\exists$-subformulas by $\top$. If $X'$ is obtained from $X$ by maximum propositionalization, then it is easy to observe that if $X'$ is invalid, then $X$ is invalid as well.

The deductive system LKg' uses this heuristic. First, we need to define some terminology.

1. The max-propositionalization $\|F\|_{\text{max}}$ of a formula $F$ is the result of replacing in $F$ all $\exists$-subformulas by $\top$, and all $\forall$-subformulas by $\top$. This process naturally extends to sequents.

4
2. The min-propositionalization $\|F\|_{\text{min}}$ of a formula $F$ is the result of replacing in $F$ all $\exists$-subformulas by $\bot$, and all $\forall$-subformulas by $\bot$. This process naturally extends to sequents.

3. A sequent is said to be max-p-invalid iff its max-propositionalization is classically invalid. A sequent is said to be min-p-valid iff its min-propositionalization is classically valid.

THE RULES OF LKg′

Below, $X$:stable means that $X$ is stable but not min-p-valid. stable. Similarly $X$:unstable means that $X$ is unstable but not min-p-valid.

$\text{Fail}$

$\bot$

$X$: max-p-invalid

$\exists$-Choose

$\Gamma, F[H(t)]$

$\Gamma, F[\exists x H(x)]:$unstable

Replicate

$\Gamma, F[\exists x H(x)], F[\exists x H(x)]$

$\Gamma, F[\exists x H(x)]:$unstable

Succ

$\top$

$X$: min-p-valid

$\forall$-Choose

$\Gamma, F[H(\alpha)]$

$\Gamma, F[\forall x H(x)]:$ stable (\(\alpha\) is a new constant)

The heuristic employed in LKg′ is quite simple and needs to be improved. For example, it does not apply well to the invalid sequent $p(a), \exists x p(x)$. It would be nice to improve our heuristic so that it can apply to a wider class of invalid sequents.
