Abstract

Rabi and Sherman [RS97] presented novel digital signature and unauthenticated secret-key agreement protocols, developed by themselves and by Rivest and Sherman. These protocols use “strong,” total, commutative (in the case of multi-party secret-key agreement), associative one-way functions as their key building blocks. Though Rabi and Sherman did prove that associative one-way functions exist if P \neq NP, they left as an open question whether any natural complexity-theoretic assumption is sufficient to ensure the existence of “strong,” total, commutative, associative one-way functions. In this paper, we prove that if P \neq NP then “strong,” total, commutative, associative one-way functions exist.

Keywords: complexity-theoretic one-way functions, associativity.

1 Introduction and Preliminaries

Rabi and Sherman [RS97] study associative one-way functions (AOWFs) and show that AOWFs exist exactly if P \neq NP. They also present the notion of strong AOWFs—AOWFs that are hard to invert even when one of their arguments is given. They give protocols due to Rivest and Sherman for two-party secret-key agreement and due to Rabi and Sherman

Work done in part while visiting the University of Rochester.
for digital signatures, that depend on strong, total AOWFs. They also outline a protocol approach for multi-party secret-key agreement that depends on strong, total, commutative AOWFs.

There are two key worries regarding the Rabi-Sherman approach. The first is whether their protocols are secure even if strong, total, commutative AOWFs exist. This worry has two facets. The first facet is that, as they note, like Diffie-Hellman [DH76,DH79], the protocol they describe has no current proof of security (even if the existence of strong, total, commutative AOWFs is given), though Rabi and Sherman give intuitively attractive arguments suggesting the plausibility of security. In particular, they prove that certain direct attacks against their protocols are precluded by the fact that the protocols use strong, total AOWFs as building blocks. The second facet of the first worry is that their definition of strong, total, commutative AOWFs is a worst-case definition, as opposed to the average-case definition one desires for a satisfyingly strong approach to cryptography.

The second worry is that Rabi and Sherman provide no evidence at all that strong, total, commutative AOWFs exist, though they do prove that AOWFs exist if $P \neq NP$. In this paper we completely remove that worry by proving that strong, total, commutative AOWFs exist if $P \neq NP$. (In light of the above-mentioned first worry—and especially its second facet—we note, as did Rabi and Sherman, that the study of AOWFs should be viewed as more of complexity-theoretic interest than of applied cryptographic interest, though it is hoped that AOWFs will in the long term prove, probably in average-case versions, to be of substantial applied cryptographic value.)

Phrasing our work in a slightly different but equivalent way, in this paper we prove that the existence of AOWFs (or, indeed, the existence of any one-way function) implies the existence of strong, total, commutative AOWFs. Furthermore, based on Kleene's [Kle52] distinction between weak and complete equality of partial functions, we give a definition of associativity that, for partial functions, is a more natural analog of the standard total-function definition than that of Rabi and Sherman, and we show that their and our results hold even under this more natural definition.

Fix the alphabet $\Sigma = \{0, 1\}$, and let $\Sigma^*$ denote the set of all strings over $\Sigma$. The length of any string $x \in \Sigma^*$ will be denoted by $|x|$. Throughout this paper, when we use “binary function” we mean “two-argument function.” Unless explicitly stated as being total, all functions may potentially be partial, i.e., “let $\sigma$ be any binary function” does not imply that $\sigma$ will necessarily be total. For any binary function $\sigma$, we will interchangeably use prefix and infix notation, i.e., $\sigma(x, y) = x \sigma y$. As is standard, pairs of strings will sometimes

---

1We mention that, after we sent this paper to them, they (Sherman, personal communication, June 1998) informed us that they had had discussions and proof sketches towards achieving the claim that strong AOWFs exist if $P \neq NP$. 
be encoded as a single string by some standard total, one-to-one, onto, polynomial-time computable pairing function, \( \langle \cdot, \cdot \rangle : \Sigma^* \times \Sigma^* \rightarrow \Sigma^* \), that has polynomial-time computable inverses, and is non-decreasing in each argument when the other argument is fixed. Let \( \text{FP} \) denote the set of all polynomial-time computable (partial) functions. Regarding Part 3 of the following definition, we mention that we use the term “one-way function” in the same way Rabi and Sherman [RS97] do, i.e., in the complexity-theoretic (that is, worst-case) sense, and without requiring that the function necessarily be injective.

**Definition 1.1** Let \( \sigma : \Sigma^* \times \Sigma^* \rightarrow \Sigma^* \) be any binary function.

1. We say \( \sigma \) is honest if and only if there exists some polynomial \( p \) such that for every \( z \in \text{range}(\sigma) \) there exists a pair \( (x, y) \in \text{domain}(\sigma) \) such that \( x\sigma y = z \) and \( |x| + |y| \leq p(|z|) \).

2. We say \( \sigma \) is FP-invertible if and only if there exists a total function \( g \in \text{FP} \) such that for every \( z \in \text{range}(\sigma) \), \( g(z) \) is some element of \( \sigma^{-1}(z) = \{ (x, y) \in \text{domain}(\sigma) \mid x\sigma y = z \} \).

3. We say \( \sigma \) is a one-way function if and only if \( \sigma \) is honest, polynomial-time computable, and not FP-invertible.

Rabi and Sherman [RS97] define a notion of associativity for binary functions as follows:

**Definition 1.2** Let \( \circ : \Sigma^* \times \Sigma^* \rightarrow \Sigma^* \) be any binary function. We say \( \circ \) is weakly associative if and only if \( x \circ (y \circ z) = (x \circ y) \circ z \) holds for all \( x, y, z \in \Sigma^* \) such that each of \( (x, y), (y, z), (x, y \circ z), \) and \( (x \circ y, z) \) is an element of \( \text{domain}(\circ) \).

This type of associativity, however, is not natural for non-total functions, since it does not evaluate as being false “equations” such as “undefined = 1010” (this can occur in \( x \circ (y \circ z) = (x \circ y) \circ z \) in various ways, e.g., if \( (x, y), (x \circ y, z), \) and \( (y, z) \) are in the domain of \( \circ \) but \( (x, y \circ z) \) is not). It would seem more natural for a definition of associativity for binary functions to require that both sides of the above equation stand or fall together. That is, for each triple of strings \( x, y, z \in \Sigma^* \), either both sides should be defined and equal, or each side should be undefined. Drawing on Kleene’s careful discussion of how to define equality between partial functions, our definition of associativity—given in Definition 1.3 below—achieves this natural behavior.

Associativity expresses equality between two functions each of which can be viewed as a 3-ary function that results from a given binary function. The distinction in the two
definitions of associativity can be said to come from two distinct interpretations of “equality” between functions, known in recursive function theory as weak equality and complete equality (see Kleene [Kle52]). Kleene suggests the use of two different equality symbols—we will use “=w” and “=c” and we have modified the following quotation to use these also—and he writes:

We now introduce “ψ(x₁,...,xₙ) =c χ(x₁,...,xₙ)” to express, for particular x₁,...,xₙ, that if either of ψ(x₁,...,xₙ) and χ(x₁,...,xₙ) is defined, so is the other and the values are the same (and hence if either of ψ(x₁,...,xₙ) and χ(x₁,...,xₙ) is undefined, so is the other). The difference in the meaning of (i) “ψ(x₁,...,xₙ) =w χ(x₁,...,xₙ)” and (ii) “ψ(x₁,...,xₙ) =c χ(x₁,...,xₙ)” comes when one of ψ(x₁,...,xₙ) and χ(x₁,...,xₙ) is undefined. Then (i) is undefined, while (ii) is true or false according as the other is or is not undefined. — [Kle52, pp. 327–328]

We feel that complete equality is the more natural of the two notions. Thus, following the notion of complete equality between functions, we propose the following definition of associativity for binary functions. Nonetheless, we will show that the results of Rabi and Sherman [RS97] and of the present paper hold even under this more restrictive definition.

In a similar vein, we also define commutativity for (partial) binary functions.

**Definition 1.3** Let σ : Σ⁺ × Σ⁺ → Σ⁺ be any binary function. Define Γ = Σ⁺ ∪ {⊥} and define an extension ˆσ : Γ × Γ → Γ of σ as follows:

$$\hat{\sigma}(a,b) = \begin{cases} \sigma(a,b) & \text{if } a \neq \perp \text{ and } b \neq \perp \text{ and } (a,b) \in \text{domain}(\sigma) \\ \perp & \text{otherwise.} \end{cases}$$

We say σ is associative if and only if, for every x, y, z ∈ Σ⁺, (x ˆσ y) ˆσ z = x ˆσ (y ˆσ z). We say σ is commutative if and only if, for every x, y ∈ Σ⁺, x ˆσ y = y ˆσ x (i.e., xσy =c yσx).

Clearly, every associative function is weakly associative, since our notion of associativity is more restrictive than weak associativity. The converse, however, is not always true, so these are indeed different notions.

**Proposition 1.4**

1. Every associative binary function is weakly associative.
2. Every total binary function is associative if and only if it is weakly associative.
3. There exists a binary function that is weakly associative, but not associative.
Proof. (1) and (2) are immediate from the definitions. To prove (3), we define the following binary function \( \sigma : \Sigma^* \times \Sigma^* \rightarrow \Sigma^* \):

\[
\sigma(a, b) = \begin{cases} 
111 & \text{if } a = 1 \text{ and } b = 11 \\
0 & \text{if } a = 111 \text{ and } b = 1111 \\
\text{undefined} & \text{otherwise.}
\end{cases}
\]

By “undefined” above we do not mean some new token “undefined,” but rather we simply mean that for cases handled by that line of the definition \((a, b) \notin \text{domain}(\sigma)\).

Let \( \hat{\sigma} \) be the extension of \( \sigma \) defined in Definition 1.3. Note that \( (1\hat{\sigma}11)\hat{\sigma}1111 = 0 \), but \( 1\hat{\sigma}(11\hat{\sigma}1111) = \bot \). Thus, \( \sigma \) is not associative. However, \( \sigma \) is weakly associative, since no three strings in \( \Sigma^* \) satisfy the four domain conditions required in Definition 1.2.

**Definition 1.5**

1. A binary function \( \sigma : \Sigma^* \times \Sigma^* \rightarrow \Sigma^* \) is an AOWF if and only if \( \sigma \) is both associative and a one-way function.

2. [RS97] A binary function \( \sigma : \Sigma^* \times \Sigma^* \rightarrow \Sigma^* \) is an \( A^w \)OWF if and only if \( \sigma \) is both weakly associative and a one-way function.

Rabi and Sherman [RS97] also introduce the notion of strong one-way functions—binary one-way functions that are hard to invert even if one of their arguments is given. Strongness clearly implies one-way-ness. (We note that “strongness” here should not be confused with the property of strong-FP-invertibility of functions introduced by Allender [All86, All85].) To avoid any possibility of ambiguity we henceforward, when using equality signs with partial functions, will make it explicit that by equality we mean \( =_c \).

**Definition 1.6**

A binary function \( \sigma \) is said to be strong if and only if \( \sigma \) is not FP-invertible even if one of its arguments is given. More formally, binary function \( \sigma \) is strong if and only if neither (a) nor (b) holds:

(a) There exists a total function \( g_1 \in \text{FP} \) such that for every \( z \in \text{range}(\sigma) \) and for each \( x \in \Sigma^* \), if \( \sigma(x, y) =_c z \) for some \( y \in \Sigma^* \), then \( \sigma(x, g_1(\langle x, z \rangle)) =_c z \).

(b) There exists a total function \( g_2 \in \text{FP} \) such that for every \( z \in \text{range}(\sigma) \) and for each \( y \in \Sigma^* \), if \( \sigma(x, y) =_c z \) for some \( x \in \Sigma^* \), then \( \sigma(g_2(\langle y, z \rangle), y) =_c z \).

2 Main Result

Rabi and Sherman [RS97] show that \( A^w \)OWFs exist if and only if \( P \neq \text{NP} \). They present no evidence that strong \( A^w \)OWFs exist, and they establish no structural conditions sufficient to imply that any exist. Solving these open questions, we show in Theorem 2.1 below that
there exist strong, total, commutative \( A^w \)OWFs (equivalently, strong, total, commutative AOWFs) if and only if \( P \neq NP \).

**Theorem 2.1** The following are equivalent.

1. \( P \neq NP \).
2. There exist \( A^w \)OWFs.
3. There exist AOWFs.
4. There exist strong, total, commutative \( A^w \)OWFs.
5. There exist strong, total, commutative AOWFs.

**Proof.** By Proposition [1.4.2, (4)](1) and (5) are equivalent. Rabi and Sherman [RS97] have shown the equivalence of (1) and (2), by exploiting the associativity of the closest common ancestor relation for configurations in the computation tree of nondeterministic Turing machines. Since (5) (and, equivalently, (4)) implies (2) and (3), and since each of (2) and (3) implies (1) (by Proposition [1.4.1](1) and by the equivalence of (1) and (2)), it suffices to show that (1) implies (5) to establish the theorem.

Assume \( P \neq NP \), and let \( A \) be a set in \( NP - P \). Let \( M \) be a nondeterministic polynomial-time Turing machine accepting \( A \). By a *witness* for “\( x \in A \)” we mean a string \( w \in \Sigma^* \) that encodes some accepting computation path of \( M \) on input \( x \). Assume, without loss of generality, that for each \( x \in A \), every witness \( w \) certifying that \( x \in A \) satisfies \( |w| = p(|x|) > |x| \) for some strictly increasing polynomial \( p \) depending on \( M \). For each string \( x \), define the set of witnesses for “\( x \in A \)” (with respect to \( M \)) by

\[
W_M(x) = \{w \mid w \text{ is a witness for } “x \in A” \}.
\]

Note that if \( x \not\in A \) then \( W_M(x) = \emptyset \).

For any strings \( u, v, w \in \Sigma^* \), \( \min(u, v) \) will denote the lexicographically smaller of \( u \) and \( v \), and \( \min(u, v, w) \) will denote the lexicographically smallest of \( u, v, \) and \( w \). Define the binary function \( \sigma : \Sigma^* \times \Sigma^* \to \Sigma^* \) by

\[
\sigma(a, b) = \begin{cases} 
\langle x, \min(w, y) \rangle & \text{if } (\exists x \in \Sigma^* \exists w, y \in W_M(x)) \left[ a = \langle x, w \rangle \land b = \langle x, y \rangle \right] \\
\langle x, x \rangle & \text{if } (\exists x \in \Sigma^* \exists w \in W_M(x)) \left[ (a = \langle x, x \rangle \land b = \langle x, w \rangle) \lor (a = \langle x, w \rangle \land b = \langle x, x \rangle) \right] \\
\text{undefined} & \text{otherwise.}
\end{cases}
\]

On our way towards a proof that (1) implies (5), we will first prove that the function \( \sigma \) defined above is a strong, commutative AOWF. Then we will show how to extend \( \sigma \) to a strong, total, commutative AOWF, thus establishing (5).
σ is clearly honest. Also, σ ∈ FP. That is, given (a, b) as the input, it is easy to decide in polynomial time whether (a, b) ∈ domain(σ), and if so, which of ⟨x, x⟩ or ⟨x, w⟩ for suitable x ∈ Σ∗ and w ∈ W_M(x) should be output as the value of σ(a, b).\footnote{Recall our assumption that for each x ∈ A, every witness w for “x ∈ A” satisfies |w| = p(|x|) > |x|. This assumption ensures that there is no ambiguity in determining whether a and b are of the form ⟨x, x⟩ or of the form ⟨x, PotentialWitness⟩, and checking items of the form ⟨x, PotentialWitness⟩ is easy as ∪_{x ∈ Σ∗} W_M(x) is in P.}

Now, we show that σ cannot be inverted in polynomial time, even if one of its arguments is given. Assume, for instance, that there exists a total function g_2 ∈ FP such that given any z in the range of σ and any second argument b for which there is some a ∈ Σ∗ with σ(a, b) =_e z, it holds that σ(g_2(⟨b, z⟩), b) =_e z. Then, contradicting our assumption that A ∉ P, A could be decided in polynomial time as follows. On input x, to decide whether or not x ∈ A, compute g_2(⟨⟨x, x⟩, ⟨x, x⟩⟩), interpret it as a pair ⟨d, e⟩, and accept if and only if d = x and e ∈ W_M(x). An analogous proof works for the case of a fixed first argument. Thus, neither (a) nor (b) of Definition 1.6 holds, so σ is a strong one-way function.

We now prove that σ is associative. Let ˆσ be the extension of σ from Definition 1.8. Fix any strings a = ⟨a_1, a_2⟩, b = ⟨b_1, b_2⟩, and c = ⟨c_1, c_2⟩ in Σ∗. Let k equal how many of a_2, b_2, and c_2 are in W_M(a_1). For example, if a_2 = b_2 = c_2 ∈ W_M(a_1), then k = 3. To show that

\[(2.a) \quad (a ˆσ b) ˆσ c = a ˆσ (b ˆσ c)\]

holds, we distinguish the following cases.

**Case 1:** [a_1 ≠ b_1 ∨ a_1 ≠ c_1 ∨ b_1 ≠ c_1]. In light of the definition of σ, we have

\[(2.b) \quad (a ˆσ b) ˆσ c = ⊥ = a ˆσ (b ˆσ c).\]

**Case 2:** [a_1 = b_1 = c_1 ∧ \{a_2, b_2, c_2\} ⊆ \{a_1\} ∪ W_M(a_1)]. \[(2.1)\] holds here too, in light of the definition of σ.

**Case 3:** [a_1 = b_1 = c_1 ∧ \{a_2, b_2, c_2\} ⊆ \{a_1\} ∪ W_M(a_1)]. In this case, note that ˆσ decreases by one the number of witnesses, in particular preserving the lexicographic minimum if both arguments contain witnesses for “a_1 ∈ A,” outputting ⟨a_1, a_1⟩ if exactly one of its arguments contains a witness for “a_1 ∈ A,” and outputting ⊥ if neither contains a witness for “a_1 ∈ A.” So it is not hard to see that (in the current case) if k ∈ \{0, 1\} then \[(2.b)\] holds, if k = 2 then

\[(a ˆσ b) ˆσ c = ⟨a_1, a_1⟩ = a ˆσ (b ˆσ c)\]

holds, and if k = 3 then

\[(a ˆσ b) ˆσ c = ⟨a_1, \min(a_2, b_2, c_2)⟩ = a ˆσ (b ˆσ c)\]
Note that in each case (2.a) is satisfied. Furthermore, it is easy to see from the definition of $\sigma$ that $\sigma$ is commutative. Thus, $\sigma$ is a strong, commutative AOWF, as claimed earlier.

Finally, to complete the proof, we now show how to extend $\sigma$ to a strong, total, commutative AOWF. The fact that $\sigma$ is an AOWF (rather than merely an $A^\circ$OWF) helps us avoid the key problem in Rabi and Sherman’s extension attempt (see Footnote 5).

Fix any string $x_0 \not\in A$ (one must exist, since $A \not\in P$). Let $a_0$ be the pair $\langle x_0, 1x_0 \rangle$. Note that $a_0$ is neither of the form $\langle x, x \rangle$ for any $x \in \Sigma^*$, nor of the form $\langle x, w \rangle$ for any $x \in \Sigma^*$ and any witness $w \in W_M(x)$ (because $x_0 \not\in A$ and thus does not have any witnesses).

Note that, by the definition of $\sigma$, extending $\tilde{\sigma}$ may not be clear to the reader; to see why this holds, one must look at the Rabi-Sherman technique of extending $\tilde{\sigma}$ to a total AOWF. However, it is far from clear that their construction achieves this. In fact, we show that any proof that their construction is valid would immediately prove that UP = NP. (Note: Valiant’s class UP consists of those languages accepted by nondeterministic polynomial-time Turing machines having the property that on all inputs they have no more than one accepting path [Val76].) In particular, we provide the following counterexample to Rabi and Sherman’s assertion, the proof of which shows that if UP $\neq$ NP then their construction does not always preserve weak associativity.

**Proposition 2.2** If UP $\neq$ NP, then there exists an $A^\circ$OWF $\tilde{\sigma}$, satisfying $(\exists a)((\tilde{\sigma}, \tilde{\sigma}) \not\in \text{domain}(\tilde{\sigma}))$ and having domain in P, such that the construction that Rabi and Sherman claim converts $A^\circ$OWFs into total $A^\circ$OWFs in fact fails on $\tilde{\sigma}$.

We prove the proposition as follows. Fix a set $A' \in \text{NP} - \text{UP}$ and an NP machine $M'$ accepting $A'$. Let the polynomial $p'$ and, for each $x$, let the witness sets $W_{M'}(x)$ be defined analogous to the definitions of $p$ and $W_M(x)$ earlier in the proof of Theorem 2.1. Define the binary function $\tilde{\sigma} : \Sigma^* \times \Sigma^* \rightarrow \Sigma^*$ by

\[
\tilde{\sigma}(a, b) = \begin{cases} 
\langle x, w \rangle & \text{if } (\exists x \in \Sigma^*) (\exists w \in W_{M'}(x)) [a = \langle x, w \rangle = b] \\
\langle x, x \rangle & \text{if } (\exists x \in \Sigma^*) (\exists w \in W_{M'}(x)) [(a = \langle x, x \rangle \wedge b = \langle x, w \rangle) \vee (a = \langle x, w \rangle \wedge b = \langle x, x \rangle)] \\
\text{undefined} & \text{otherwise.}
\end{cases}
\]

It is not hard to verify that $\tilde{\sigma}$ is indeed an $A^\circ$OWF. Let $\tilde{a}$ be a fixed string such that $\langle \tilde{a}, \tilde{a} \rangle \not\in \text{domain}(\tilde{\sigma})$. For the particular function $\tilde{\sigma}$ defined above, such a string $\tilde{a}$ indeed exists (e.g., let $\tilde{a} = \langle x_0, 1x_0 \rangle$ for any particular fixed $x_0 \not\in A'$, see the discussion of $a_0$ in the proof of Theorem 2.1). For UP, $\tilde{\sigma}$ may not in general exist. Now, using the Rabi-Sherman technique, extend $\tilde{\sigma}$ to a total function, $\tilde{\tau}$, the same way we will obtain the total extension $\tau$ of $\sigma$ later in the proof of Theorem 2.1.

Fix some string $\tilde{x} \in A'$ that has two distinct witnesses $w$ and $y$ in $W_{M'}(\tilde{x})$ (such $\tilde{x}$, $w$, and $y$ exist, as $A' \not\in \text{UP}$), and let $a = \langle \tilde{x}, w \rangle$, $b = \langle \tilde{x}, y \rangle$, and $c = \langle \tilde{x}, \tilde{x} \rangle$. Then, we have $(\tilde{a} \tilde{b})\tilde{c} = \tilde{a} \not\neq \langle \tilde{x}, \tilde{x} \rangle = \tilde{a} \tilde{c}$, and thus $\tilde{\tau}$ is not associative (and thus, as it is total, is not weakly associative). (The reason that $(\tilde{a} \tilde{b})\tilde{c} = \tilde{a}$ may not be clear to the reader; to see why this holds, one must look at the Rabi-Sherman technique of extending $\tilde{\sigma}$ to $\tilde{\tau}$, which, very informally, is to use $\tilde{a}$ as a dumping ground.) We mention that, for essentially the same reason, $\tilde{\sigma}$ is not associative (and thus is not an AOWF), since $(\tilde{a} \tilde{b})\tilde{c} = \neq \langle \tilde{x}, \tilde{x} \rangle = \tilde{a} \tilde{b} \tilde{c}$, where $\tilde{\sigma}$ is the extension of $\tilde{\sigma}$ from Definition 1.3.

Even if Rabi and Sherman’s proof were valid, their claim would not be particularly useful to them, as the $A^\circ$OWFs they construct [RS97, proof of Theorem 5] do not in general have domains that are in P. In contrast, our $\sigma$ does have a domain that is in P, and their method (corrected to remove the “c” problem) does preserve associativity (note: we did not say weak associativity), and so is useful to us.
\( \tau(a, b) = \sigma(a, b) \); otherwise, define \( \tau(a, b) = a_0 \).

\( \tau \) is a strong, total, commutative AOWF. In particular, \( \tau \) is honest, since for \( a_0 \), which is the only string in the range of \( \tau \) that is not in the range of \( \sigma \), it holds that \( \tau(a_0, a_0) = a_0 \) and \( |a_0| + |a_0| \leq 2|a_0| \). Also, \( \tau \in \text{FP} \), since \( \sigma \in \text{FP} \) and \( \text{domain}(\sigma) \in \text{P} \). That \( \tau \) is strong follows from the facts that \( \text{range}(\sigma) \subseteq \text{range}(\tau) \) and \( \sigma \) is strong. Finally, to see that \( \tau \) is associative, note that if \( a\hat{\sigma}(b\hat{\sigma}c) = \bot \) then \( a\tau(b\tau c) = a_0 \) and otherwise \( a\tau(b\tau c) = a\hat{\sigma}(b\hat{\sigma}c) \). Similarly, if \( \hat{\sigma}(a\hat{\sigma}b\hat{\sigma}c) = \bot \) then \( (a\tau b)\tau c = a_0 \) and otherwise \( (a\tau b)\tau c = (a\hat{\sigma}b)\hat{\sigma}c \). The associativity of \( \tau \) now follows easily, given that \( \sigma \) is associative. Hence, \( \tau \) is a strong, total, commutative AOWF.

Rabi and Sherman emphasize the importance of explicitly exhibiting strong, total AOWFs [RS97], since the cryptographic protocols given in [RS97] rely on their existence, and they also pose as an open issue the problem of whether a strong, total AOWF can be constructed from any given one-way function [RS93]. The proof of Theorem 2.1 solves these open issues. Indeed, the function \( \tau \) defined in the above proof shows how to construct a strong, total, commutative AOWF (equivalently, a strong, total, commutative AOWF) based on any clocked NP machine accepting a language in \( \text{NP} - \text{P} \). Similarly, the proof of Theorem 2.1 shows how, given any one-way function (along with its polynomial runtime and honesty bounds), one can obtain a clocked NP machine accepting a language in \( \text{NP} - \text{P} \). Thus, as the title of this paper claims, from any given one-way function one can create a strong, total, commutative AOWF (equivalently, a strong, total, commutative AOWF).

Finally, we mention briefly the issue of injective (i.e., one-to-one) AOWFs and AOWFs. Valiant’s class UP (unambiguous polynomial time [Val76], see Footnote 5) has long played a central role in complexity-theoretic cryptography. Rabi and Sherman give no evidence that injective AOWFs might exist. In fact, they prove that no total AOWF can be injective. Thus, in light of Proposition 1.4.2, no total AOWF can be injective. However, as Theorem 2.3 we show that \( \text{P} \neq \text{UP} \) if and only if injective AOWFs (and indeed injective AOWFs) exist.

Is the lack of injectivity for total commutative AOWFs and AOWFs an artifact of commutativity? Consider any commutative function \( \sigma \) such that there exist elements \( a \) and \( b \) with \( a \neq b \) and \( (a, b) \in \text{domain}(\sigma) \). Then \( \sigma(a, b) = \sigma(b, a) \), and so \( \sigma \) is not injective. Now let us generalize the notion of injectivity so as to keep the general intuition of its behavior, yet so as to not to clash so strongly with commutativity. Given any binary function \( \sigma : \Sigma^* \times \Sigma^* \rightarrow \Sigma^* \), we say \( \sigma \) is unordered-injective if and only if for all \( a, b, c, d \in \Sigma^* \), if \( (a, b), (c, d) \in \text{domain}(\sigma) \) and \( \sigma(a, b) = \sigma(c, d) \), then \( \{a, b\} = \{c, d\} \). That is, each element \( x = \sigma(a, b) \) in the range of \( \sigma \) has at most one unordered pair \( \{a, b\} \) (possibly
degenerate, i.e., \( \{a, a\} = \{a\} \) as its preimage. If \( \sigma \) is commutative, then both orderings of this unordered pair, \((a, b)\) and \((b, a)\), will map to \(x\); if not, one cannot know (i.e., \( \sigma(a, b) =_c x \) but \( \sigma(b, a) =_c y \neq x \) is possible).

**Theorem 2.3** The following are equivalent:

1. \( P \neq \text{UP} \).
2. There exist injective \( A^0 \text{OWFs} \).
3. There exist injective \( \text{AOWFs} \).
4. There exist strong, commutative, unordered-injective \( A^0 \text{OWFs} \).
5. There exist strong, commutative, unordered-injective \( \text{AOWFs} \).

### 3 Conclusions

So, in this paper, we have shown that \( P \neq \text{NP} \) is a sufficient condition for strong, total, commutative \( \text{AOWFs} \) (equivalently, for strong, total, commutative \( A^0 \text{OWFs} \)) to exist. Since by standard techniques (namely, the natural binary-function injectivity-not-required analog of a result of Grollmann and Selman [GS88, Sel92], see also [Ko85]), \( P \neq \text{NP} \) is also a necessary condition for the existence of such functions, we obtain a complete characterization. This characterization solves the conjecture of Rabi and Sherman that strong \( A^0 \text{OWFs} \) exist [RS97], insofar as one can solve it without solving the \( P =? \text{NP} \) question. Moreover, our proofs have shown how to construct a strong, total, commutative \( \text{AOWF} \) (equivalently, a strong, total, commutative \( A^0 \text{OWF} \)) from any given one-way function, which resolves an open problem of Rabi and Sherman [RS93].

We mention that most cryptographic applications are in general concerned with average-case complexity and randomized algorithms instead of worst-case complexity and...
deterministic algorithms. However, as Rabi and Sherman stress, the intriguing concept of (weakly) associative one-way functions, particularly when they are total and strong and ideally in an average-case version, may be expected to be useful in many cryptographic applications such as in the key-agreement protocol proposed by Rivest and Sherman in 1984 (see [RS97]), and may eventually offer elegant solutions to a variety of practical cryptographic problems.

Acknowledgments. We thank Alan Selman for sharing with us his knowledge of the history and literature of partial functions, and of Kleene’s work.
