The archetypal equation and its solutions attaining the global extremum

Mariusz Sudzik

Abstract. Let \((\Omega, \mathcal{F}, \mathbb{P})\) be a probability space and let \(\alpha, \beta : \mathcal{F} \to \mathbb{R}\) be random variables. We provide sufficient conditions under which every bounded continuous solution \(\varphi : \mathbb{R} \to \mathbb{R}\) of the equation \(\varphi(x) = \int_{\Omega} \varphi(\alpha(\omega)(x - \beta(\omega))) \mathbb{P}(d\omega)\) is constant. We also show that any non-constant bounded continuous solution of the above equation has to be oscillating at infinity.

Mathematics Subject Classification. Primary 39B22, Secondary 39B05.

Keywords. Archetypal equation, Linear functional equation, Equation with rescaling, Iterative equation, Bounded continuous function, Global extremum.

1. Introduction

The paper concerns the linear functional equation of infinite order

\[
\varphi(x) = \int \int_{\mathbb{R}^2} \varphi(a(x - b)) \mu(da, db),
\]

where \(\mu\) is a given Borel probability measure on \(\mathbb{R}^2\). We can think about equation (1.1) also in the language of random variables. Given a probability space \((\Omega, \mathcal{F}, \mathbb{P})\) let \((\alpha, \beta) : \Omega \to \mathbb{R}^2\) be a fixed random vector with a distribution \(\mu\). Then the equation

\[
\varphi(x) = \int_{\Omega} \varphi(\alpha(\omega)(x - \beta(\omega))) \mathbb{P}(d\omega)
\]

is equivalent to (1.1).

The study of equation (1.1) was initiated by Derfel [5] in 1989. He considered equation (1.2) under the additional assumption \(\alpha > 0\) a.s. and he noticed...
that the behaviour of solutions of (1.1) crucially depends on the value of the integral
\[ K := \int_{\mathbb{R}^2} \ln |a| \mu(da, db). \] (1.3)

He proved that, under some additional technical assumptions, if \( K \in (-\infty, 0) \) then equation (1.1) has only trivial, i.e. constant, solutions in the class of bounded continuous functions. If \( K \in (0, \infty) \) and \( \alpha > 0 \) a.s., then he constructed a non-trivial bounded continuous solution. The details of this theorem and its proof are included in [4], Theorem 1.1.

Many deep results connected with equation (1.1) were obtained and collected by Bogachev et al. [3] and [4]. In those papers equation (1.1) was named by the authors as the \textit{archetypal equation} since it is a rich source of many famous functional and differential-functional equations. For instance, one can obtain a balanced version of the pantograph equation; details can be found in [4]. It is worth noting that functional equations of a more general form than (1.2) were also considered in the literature; an interested reader, can find them e.g. among papers written by Polish mathematicians from the Silesian University: Baron, Kapica and Morawiec (see, for instance, [2] and [8]). Moreover, a lot of interesting remarks connected with the archetypal equation, its special cases and equations of similar forms can be found in [1] and [6].

Here we can confine ourselves to (1.1) since equations with linearly transformed arguments are of prominent interest in applications. We have to add that the main results obtained in this paper hold under the condition
\[ \mathbb{P}(\alpha < 0) > 0. \] (1.4)

In this case we still do not have extensive knowledge about the existence of non-constant solutions of the archetypal equation in the class of bounded continuous functions. It is worth noting that every absolutely continuous solution of (1.1) whose derivative belongs to \( L^1(\mathbb{R}) \) is constant when (1.4) holds (see Theorem 4.5 from [3]). Furthermore we are able to obtain and describe all bounded continuous solutions of the archetypal equation when (1.4) holds only if \( |\alpha| = 1 \) a.s. (see Theorem 2.3 from [4]). Each of them is uniformly continuous. It was also proved in [4] that if \( |\alpha| \neq 1 \) a.s. and \( K \leq 0 \), then every bounded and uniformly continuous solution of (1.1) is constant. The problem of the existence or non-existence of non-trivial solutions of (1.1) when (1.4) is true and \( K > 0 \) is still open today.

In the present paper we will prove that, under some mild technical assumption imposed on the measure \( \mu \), every bounded continuous solution of (1.1) reaching the global extreme value must be constant. In the proof we make use of the method in [9]. In the third section we prove some results connected with the asymptotical behaviour of bounded continuous solutions of the archetypal equation.
2. Solutions attaining the global extreme value

Let us begin with a simple observation.

Remark 2.1. Note that each constant function is a solution of the archetypal equation since $\mu$ is a probability measure. Furthermore, the linear combination of solutions of (1.1) is still its solution. Hence, studying bounded solutions $\varphi : \mathbb{R} \to \mathbb{R}$ of (1.1) which attain their global extremum we can assume without loss of generality that $\min \varphi(\mathbb{R}) = 0$ and $\sup \varphi(\mathbb{R}) \leq 1$.

By the support of a Borel measure $\mu$ on $\mathbb{R}^n$, where $n \in \mathbb{N}$, we mean the set $\text{supp} \mu$ of all $x \in \mathbb{R}^n$ such that each neighborhood of $x$ is of positive measure $\mu$. Observe that $\text{supp} \mu$ is a closed subset of $\mathbb{R}^n$. In what follows $\mu$ stands for an arbitrary Borel probability measure on $\mathbb{R}^2$.

We prove the following technical lemma which will be our basic tool in the proof of the main theorems.

Lemma 2.2. Let $\varphi : \mathbb{R} \to [0, +\infty)$ be a continuous solution of equation (1.1) and let $x_0 \in \mathbb{R}$ be such that $\varphi(x_0) = 0$. Then

$$
\varphi \left( c_p c_{p-1} \cdots c_1 x_0 - \sum_{i=1}^{p} c_p \cdots c_i d_i \right) = 0
$$

for all $p \in \mathbb{N}$ and $(c_1, d_1), \ldots, (c_p, d_p) \in \text{supp} \mu$.

Proof. Let $p \in \mathbb{N}$ be fixed and assume that $(c_1, d_1), \ldots, (c_p, d_p) \in \text{supp} \mu$. Applying equality (1.1) to $x_0$ we get

$$
0 = \varphi(x_0) = \int_{\mathbb{R}^2} \varphi(a(x_0 - b)) \mu(da, db).
$$

Since $\varphi$ is continuous and nonnegative, we have

$$
\varphi(a(x_0 - b)) = 0 \text{ for all } (a, b) \in \text{supp} \mu.
$$

In particular, we get $\varphi(c_1 x_0 - c_1 d_1) = 0$. If we repeat this reasoning $p - 1$ times to the points $c_j \cdots c_1 x_0 - \sum_{i=1}^{j} c_j \cdots c_i d_i$ and the pairs $(c_{j+1}, d_{j+1})$, $j = 1, \ldots, p - 1$, in turn, we obtain the assertion. \qed

We will also prove a lemma which asserts that some subsets are dense in $\mathbb{R}$. The statement is obvious but it can help to draw attention to the crucial properties of sets which are considered in the proof of Theorem 2.4. We will also present a simple proof of the lemma for the sake of completeness.

Lemma 2.3. Let $t \in \mathbb{R} \setminus \{0\}$, $v \in (1, +\infty)$ and let $(u_n)_{n \in \mathbb{N}}$ be a sequence of real numbers. Then the set $D = \bigcup_{n=1}^{+\infty} D_n$, where

$$
D_n := \left\{ u_n + \frac{st}{v^n} : s \in \mathbb{Z} \right\}
$$

for all $n \in \mathbb{N}$, is dense in $\mathbb{R}$.
Proof. We will consider the case when \( t \) is positive. We fix \( a, b \in \mathbb{R} \) such that \( a < b \) and define the interval \( I = (a, b) \). We have to show that \( I \cap D \) is nonempty. Let \( n_0 \in \mathbb{N} \) be such that

\[
\frac{t}{v^{n_0}} < b - a. \tag{2.1}
\]

Let \( s_0 \) be the greatest number of \( \mathbb{Z} \) for which

\[ u_{n_0} + \frac{s_0 t}{v^{n_0}} \leq a. \]

Hence, by the definition of the number \( s_0 \), we have

\[ u_{n_0} + \frac{s_0 t + t}{v^{n_0}} > a. \]

Moreover, using the definition of \( s_0 \) and inequality (2.1) we get

\[ u_{n_0} + \frac{s_0 t + t}{v^{n_0}} = u_{n_0} + \frac{s_0 t}{v^{n_0}} + \frac{t}{v^{n_0}} \leq a + \frac{t}{v^{n_0}} < b. \]

Therefore \( u_{n_0} + \frac{s_0 t + t}{v^{n_0}} \in I \). It means that \( D \) is dense in \( \mathbb{R} \). If \( t \) is negative then the proof is similar, so we omit it. \( \square \)

**Theorem 2.4.** If \( \mu \left(((-\infty, 0) \setminus \{-1\}) \times \mathbb{R}\right) > 0 \) and there exists \( b \in \mathbb{R} \setminus \{0\} \) such that \((1, b) \in \text{supp} \mu\), then every bounded continuous solution of equation \((1.1)\) attaining its global extremum is constant.

**Remark 2.5.** It is worth mentioning that the assumption of the boundedness of \( \varphi \) in Theorem 2.4 is essential only in the case \( \mu(\mathbb{Z} \times \mathbb{R}) = 1 \).

**Proof.** The pair \((1, b)\) will be denoted by \((a_0, b_0)\) from this point. Take any bounded continuous solution \( \varphi : \mathbb{R} \to \mathbb{R} \) of \((1.1)\) attaining its global extremum. In view of Remark 2.1 we can assume that \( \varphi : \mathbb{R} \to [0, 1] \) and there exists \( x_0 \in \mathbb{R} \) such that \( \varphi(x_0) = 0 \). Since \( \varphi \) is continuous, it is sufficient to show that \( \varphi \) takes value 0 on some dense subset \( D \) of the real line. The proof is split into the three general cases and in each of them we will describe how to obtain the desired dense set. We shall examine each of the following situations:

**I.** \( \text{supp} \mu \cap ((\mathbb{R} \setminus \mathbb{Q}) \times \mathbb{R}) \neq \emptyset \),

**II.** \( \text{supp} \mu \cap ((\mathbb{Q} \setminus \mathbb{Z}) \times \mathbb{R}) \neq \emptyset \),

**III.** \( \text{supp} \mu \subseteq \mathbb{Z} \times \mathbb{R} \).

Furthermore we distinguish two complementary subcases for both case I and case II.

**I.A.** There exist \( a \in (\mathbb{R} \setminus \mathbb{Q}) \cap (-\infty, 0) \) and \( b \in \mathbb{R} \) such that \((a, b) \in \text{supp} \mu\).

**I.B.** If \((a, b) \in \text{supp} \mu \) and \( a \in \mathbb{R} \setminus \mathbb{Q} \), then \( a \) is positive.

**II.A.** There exist \( a \in (\mathbb{Q} \setminus \mathbb{Z}) \cap (-\infty, 0) \) and \( b \in \mathbb{R} \) such that \((a, b) \in \text{supp} \mu\).

**II.B.** If \((a, b) \in \text{supp} \mu \) and \( a \in \mathbb{Q} \setminus \mathbb{Z} \), then \( a \) is positive.
In summary, we obtain the five cases (I.A, I.B, II.A, II.B and III) and note that the measure $\mu$ fulfills at least one of them. We shall prove that in each one the function $\varphi$ is constant.

**I.A.** Assume that there exists $(a, b) \in \text{supp}\mu$ such that $a \in (-\infty, 0) \setminus \mathbb{Q}$. Put $(a_1, b_1) := (a, b)$ and remember that $a_0 = 1$ and $b_0 \neq 0$. Fix also arbitrary $k, l \in \mathbb{N}$. If we apply Lemma 2.2 with $(c_i, d_i) = (a_0, b_0)$, where $i = 1, 2, \ldots, k$, then we obtain the equality $\varphi(x_0 - k b_0) = 0$ since $a_0 = 1$. Applying equality (1.1) for $x_0 - k b_0$ one can deduce that

$$\varphi(a_1(x_0 - b_1) - a_1 k b_0) = 0.$$  

Finally, if we use Lemma 2.2 with $(c_i, d_i) = (a_0, b_0)$, where $i = 1, 2, \ldots, l$, to the point $a_1(x_0 - b_1) - a_1 k b_0$, then we will get

$$\varphi(a_1(x_0 - b_1) - (k a_1 + l) b_0) = 0.$$  

The Kronecker density theorem [7, Chapter XXIII] asserts that the set

$$\{k a_1 + l : k, l \in \mathbb{N}\}$$  

is dense in $\mathbb{R}$. Hence

$$\{a_1(x_0 - b_1) - (k a_1 + l) b_0 : k, l \in \mathbb{N}\}$$  

is also dense as $b_0 \neq 0$. This implies that $\varphi$ is constant and the proof is complete in this subcase.

**I.B.** This case means that if $(a, b) \in \text{supp}\mu$ and $a$ is negative, then $a \in \mathbb{Q}$. Since $\mu((-\infty, 0) \times \mathbb{R}) > 0$ there exists $(a, b) \in \text{supp}\mu$ with $a < 0$. Put $(a_1, b_1) := (a, b)$. Then $a_1 \in \mathbb{Q}$. Take also $(a_2, b_2) \in \text{supp}\mu$ with $a_2 \in \mathbb{R} \setminus \mathbb{Q}$. Then $a_2 > 0$. As before we obtain the equality $\varphi(a_1(x_0 - b_1) - a_1 k b_0) = 0$, where $k \in \mathbb{N}$ is fixed. In the next step, applying equality (1.1) to $a_1(x_0 - b_1) - a_1 k b_0$, we get

$$\varphi(a_1 a_2(x_0 - b_1) - a_2 b_2 - a_1 a_2 k b_0) = 0.$$  

Fix an arbitrary $l \in \mathbb{N}$. Finally, we apply Lemma 2.2 with $(c_i, d_i) = (a_0, b_0)$ for $i = 1, \ldots, l$ to the point $a_1 a_2(x_0 - b_1) - a_2 b_2 - a_1 a_2 k b_0$. As a result we have

$$\varphi(a_1 a_2(x_0 - b_1) - a_2 b_2 - (l + a_1 a_2 k) b_0) = 0.$$  

Note that $a_1 a_2$ is a negative irrational number, so again using the Kronecker density theorem we have constructed a dense subset $D$ of $\mathbb{R}$ while $k, l$ runs through $\mathbb{N}$. The proof is complete in this case.

**II.** Now we assume that $\text{supp}\mu \cap \left((\mathbb{Q} \setminus \mathbb{Z}) \times \mathbb{R}\right) \neq \emptyset$. Since we are done in case I we may assume that $\text{supp}\mu \subseteq \mathbb{Q} \times \mathbb{R}$. Let $A \subseteq \mathbb{Q}$ be the smallest set such that $\text{supp}\mu \subseteq A \times \mathbb{R}$, i.e.

$$A = \{a \in \mathbb{Q} : (a, b) \in \text{supp}\mu \text{ for some real } b\}.$$  

Then there is a set $I \subseteq \mathbb{N} \cup \{0\}$ and an injective sequence $(a_i)_{i \in I}$ such that $A = \{a_i : i \in I\}$. Moreover, we can take $I = \{0, 1, \ldots, n - 1\}$ if $A$ has exactly $n$ elements and $I = \mathbb{N} \cup \{0\}$ when $A$ is infinite. Observe that the condition
supp $\mu \cap ((\mathbb{Q} \setminus \mathbb{Z}) \times \mathbb{R}) \neq \emptyset$, assumed in the present case II, means that $A \setminus \mathbb{Z} \neq \emptyset$. For every $i \in I$ we also define a Borel measure $\mu_i$ by the equality

$$
\mu_i(B) = \mu(\{a_i\} \times B) \text{ for each Borel } B \subseteq \mathbb{R}.
$$

Note that for any $i \in I$ we also define a Borel measure $\mu_i$ by the equality

$$
\mu_i(B) = \mu(\{a_i\} \times B) \text{ for each Borel } B \subseteq \mathbb{R}.
$$

For every $i \in I$ we have $\mu_i(\mathbb{R}) \in (0, 1)$ and $\sum_{i \in I} \mu_i(\mathbb{R}) = 1$. Moreover, equation (1.1) can be rewritten in the form

$$
\varphi(x) = \sum_{i \in I} \int_{\mathbb{R}} \varphi(a_i(x - b)) \mu_i(db).
$$

II.A. In this case there exists $i \in I$ such that $a_i$ is negative and noninteger. First of all remember that $a_0 = 1$ and $b_0 \neq 0$. Without loss of generality we may assume that $i = 1$. In other words $a_1 \in (-\infty, 0) \cap (\mathbb{Q} \setminus \mathbb{Z})$. Then there exist coprimes $q, q_0 \in \mathbb{Z}$ such that $a_1 = q/q_0$ and $q < 0$. The definitions of $q, q_0$ and $a_1$ imply that $q_0 \geq 2$. We fix also any $b_1 \in \mathbb{R}$ for which $(a_1, b_1) \in \text{supp} \mu$. Define the sequence $(D_n)_{n \in \mathbb{N}}$ of sets putting

$$
D_n := \left\{ a_1^n x_0 - \sum_{i=1}^{n} a_i b_1 - \frac{s b_0}{q_0} : s \in \mathbb{Z} \right\}
$$

and let

$$
D := \bigcup_{n=1}^{+\infty} D_n.
$$

Since $b_0 \neq 0$ and $q_0 > 1$, the density of the set $D$ follows from Lemma 2.3.

Our goal is to prove that the function $\varphi$ vanishes on $D$. We shall use mathematical induction with respect to $n$. In the first step we show that $\varphi_{|D_1} = 0$, i.e.

$$
\varphi\left( a_1(x_0 - b_1) - \frac{s b_0}{q_0} \right) = 0 \text{ for all } s \in \mathbb{Z}.
$$

Fix any $k, l \in \mathbb{N} \cup \{0\}$. In the beginning note that we can obtain the equality

$$
0 = \varphi\left( a_1(x_0 - b_1) - a_1 k b_0 \right) = \varphi\left( a_1(x_0 - b_1) - \frac{q k}{q_0} b_0 \right)
$$

in the same way as in point I.A. If we apply Lemma 2.2 with $(c_j, d_j) = (a_0, b_0)$, where $j = 1, 2, \ldots, l$, to the point $a_1(x_0 - b_1) - \frac{q k}{q_0} b_0$, then we will get

$$
\varphi\left( a_1(x_0 - b_1) - \frac{q k}{q_0} b_0 \right) = \varphi\left( a_1(x_0 - b_1) - \frac{q_0 l}{q_0} + \frac{q k}{q_0} b_0 \right) = 0. \quad (2.3)
$$

Note that the expression $q_0 l + q k$ runs through the whole $\mathbb{Z}$, while $k, l \in \mathbb{N} \cup \{0\}$, since $q$ and $q_0$ are coprime and of different signs. Therefore equality (2.3) implies that

$$
\varphi(x) = 0 \text{ for every } x \in D_1.
$$
Let \( n \in \mathbb{N} \) be fixed and assume that \( \varphi |_{D_n} = 0 \). We prove that \( \varphi |_{D_{n+1}} = 0 \).

Take any \( s \in \mathbb{Z} \), put

\[
r = a_1^{n+1}x_0 - \sum_{i=1}^{n+1} a_i^1 b_1 - \frac{sb_0}{q_0^{n+1}}
\]

and observe that \( r \in D_{n+1} \).

Since \( q \) and \( q_0 \) are coprime and of different signs, we can find \( k, l \in \mathbb{N} \cup \{0\} \) such that \( q_0^{n+1}l + qk = s \). If we use the induction hypothesis and equality (2.2), then we will get

\[
0 = \varphi \left( a_1^n x_0 - \sum_{i=1}^{n} a_i^1 b_1 - \frac{kb_0}{q_0^n} - b \right)
= \sum_{j \in I} \int_{\mathbb{R}} \varphi \left( a_j \left( a_1^n x_0 - \sum_{i=1}^{n} a_i^1 b_1 - \frac{kb_0}{q_0^n} - b \right) \right) \mu_j(db),
\]

and thus, as \( \varphi \) is non-negative,

\[
\int_{\mathbb{R}} \varphi \left( a_j \left( a_1^n x_0 - \sum_{i=1}^{n} a_i^1 b_1 - \frac{kb_0}{q_0^n} - b \right) \right) \mu_j(db) = 0 \text{ for all } j \in I.
\]

In particular, for \( j = 1 \) we have

\[
\int_{\mathbb{R}} \varphi \left( a_1 \left( a_1^n x_0 - \sum_{i=1}^{n} a_i^1 b_1 - \frac{kb_0}{q_0^n} - b \right) \right) \mu_1(db) = 0.
\]

The function \( \varphi \) is non-negative and continuous. Hence

\[
\varphi \left( a_1 \left( a_1^n x_0 - \sum_{i=1}^{n} a_i^1 b_1 - \frac{kb_0}{q_0^n} - b \right) \right) = 0 \text{ for every } b \in \text{supp}\mu_1.
\]

Taking \( b = b_1 \) in the above equality we get

\[
\varphi \left( a_1^{n+1} x_0 - \sum_{i=1}^{n+1} a_i^1 b_1 - a_1 b_1 - a_1 \frac{kb_0}{q_0^n} \right) = 0.
\]

Thus, using the representation \( a_1 = q/q_0 \), we come to the equality

\[
\varphi \left( a_1^{n+1} x_0 - \sum_{i=1}^{n+1} a_i^1 b_1 - \frac{qkb_0}{q_0^{n+1}} \right) = 0.
\]

Recall that \( a_0 = 1 \) and the numbers \( k \) and \( l \) were chosen so that the sum \( q_0 l^{n+1} + qk \) is equal to \( s \). If we apply Lemma 2.2 with \( (c_j, d_j) = (a_0, b_0) \), where \( j = 1, 2, \ldots, l \), to the point \( a_1^{n+1} x_0 - \sum_{i=1}^{n+1} a_i^1 b_1 - \frac{qkb_0}{q_0^{n+1}} \), then we will get

\[
\varphi \left( a_1^{n+1} x_0 - \sum_{i=1}^{n+1} a_i^1 b_1 - \frac{qkb_0}{q_0^{n+1}} - b_0 \right) = 0.
\]
Recall that we have \( a \), \( b \) that is \( 512 \). Sudzik
\[ m \in \text{of sets (in this case is analogous to that of the previous subcase. This time a sequence } \phi \]

The above equality means that \( \phi(r) = 0 \). Since \( r \) was an arbitrary element of \( D_{n+1} \), we have proven that
\[ \phi(x) = 0 \text{ for every } x \in D_{n+1}. \]

Consequently, by mathematical induction, we get \( \phi|_D = 0 \) and the proof has been completed in case II.A.

**II.B.** In this case \( A \setminus \mathbb{Z} \neq \emptyset \) and each negative element of \( A \) is an integer. Recall that we have \( a_0 = 1 \) and \( b_0 \neq 0 \). We know that \( \mu((-\infty,0) \times \mathbb{R}) > 0 \). This condition implies that we can choose \( i \in I \) such that \( a_i \in (-\infty,0) \). All such numbers are, in view of the assumptions of case II.B, integers. Without loss of generality we may assume that \( i = 1 \). Then \( a_1 \in \mathbb{Z} \). Take an arbitrary \( b_1 \in \text{supp}_\mu I \). Since \( \emptyset \neq A \setminus \mathbb{Z} \subseteq \mathbb{Q} \setminus \mathbb{Z} \) we may assume that \( a_2 \in \mathbb{Q} \setminus \mathbb{Z} \).

Take any \( b_2 \in \text{supp}_\mu I \). Then \( a_2 \) must be positive. We also define a parameter \( m \in \mathbb{N} \) such that \( a_1 a_2^m \in \mathbb{Q} \setminus \mathbb{Z} \) since it may happen that \( a_1 a_2 \in \mathbb{Z} \). There exist coprimes \( q, q_0 \in \mathbb{Z} \) for which \( a_1 a_2^m = q/q_0 \) and \( q < 0 \). Then \( q_0 \geq 2 \). The proof in this case is analogous to that of the previous subcase. This time a sequence of sets \( (D_n)_{n \in \mathbb{N}} \) will be defined by
\[ D_n := \left\{ (a_1 a_2^m)^n x_0 - \sum_{i=1}^{n} (a_1 a_2^m)^i b_1 - \sum_{i=0}^{m} \sum_{j=1}^{m} a_i^i a_2^{im+j} b_2 - \frac{sb_0}{q_0^n} : s \in \mathbb{Z} \right\} \]

and again we put
\[ D = \bigcup_{n=1}^{+\infty} D_n. \]

We have \( b_0 \neq 0 \) and \( q_0 > 1 \). Define a sequence \( (u_n)_{n \in \mathbb{N}} \) by
\[ u_n = (a_1 a_2^m)^n x_0 - \sum_{i=1}^{n} (a_1 a_2^m)^i b_1 - \sum_{i=0}^{m} \sum_{j=1}^{m} a_i^i a_2^{im+j} b_2. \]

Then, in view of Lemma 2.3, we will get the density of \( D \). Again we shall use mathematical induction to prove that \( \phi \) is constant on \( D \). First of all we are going to show that \( \phi|_{D_1} = 0 \). As previously we start with the equality
\[ \phi(a_1(x_0 - b_1) - a_1 k b_0) = 0, \]
where \( k \in \mathbb{N} \cup \{0\} \) is fixed. If we apply Lemma 2.2 with \( (c_j, d_j) = (a_2, b_2) \), where \( j = 1, 2, \ldots, m \), to the point \( a_1(x_0 - b_1) - a_1 k b_0 \), then we will get
\[ \phi \left( a_1 a_2^m (x_0 - b_1) - \sum_{i=1}^{m} a_i^i b_2 - a_1 a_2^m k b_0 \right) = 0. \]
Since $a_1a_2^m = q/q_0$, we have
\[
\varphi \left( a_1a_2^m(x_0 - b_1) - \sum_{i=1}^{m} a_2^i b_2 - \frac{qk}{q_0} b_0 \right) = 0.
\]

Fix any $l \in \mathbb{N} \cup \{0\}$. If we use Lemma 2.2 with $(c_j, d_j) = (a_0, b_0)$, where $j = 1, \ldots, l$, to the point from the above equality, then we will obtain
\[
\varphi \left( a_1a_2^m(x_0 - b_1) - \sum_{i=1}^{m} a_2^i b_2 - \frac{qk + q_0 l}{q_0} b_0 \right) = 0,
\]
that is
\[
\varphi \left( a_1a_2^m(x_0 - b_1) - \sum_{i=1}^{m} a_2^i b_2 - \frac{qk + q_0 l}{q_0} b_0 \right) = 0.
\]
Note that $q$ and $q_0$ are coprime and they have different signs which implies that the expression $qk + q_0 l$ can take any integer value when $k, l$ run through $\mathbb{N} \cup \{0\}$. Hence
\[
\varphi(x) = 0 \text{ for every } x \in D_1.
\]

Fix $n \in \mathbb{N}$ and assume that $\varphi|_{D_n} = 0$. We will show the equality $\varphi|_{D_{n+1}} = 0$. Take any $s \in \mathbb{Z}$ and put
\[
r := (a_1a_2^m)^{n+1} x_0 - \sum_{i=1}^{n+1} (a_1a_2^m)^i b_1 - \sum_{i=0}^{n} \sum_{j=1}^{m} a_1^i a_2^{im+j} b_2 - \frac{sb_0}{q_0^{n+1}}.
\]
Note that $r$ is a member of the set $D_{n+1}$. We show that $\varphi(r) = 0$. As in the proof of case II.A we fix $k, l \in \mathbb{N} \cup \{0\}$ such that $lq_0^{n+1} + kq = s$. Such a choice is possible since $q$ and $q_0$ are coprime and $q < 0 < q_0$. Moreover, we have
\[
\varphi \left( (a_1a_2^m)^n x_0 - \sum_{i=1}^{n} (a_1a_2^m)^i b_1 - \sum_{i=0}^{n-1} \sum_{j=1}^{m} a_1^i a_2^{im+j} b_2 - \frac{kb_0}{q_0^n} \right) = 0
\]
since the argument from the above equality belongs to $D_n$. Applying equality (2.2) to the point from the last equality, for every $i \in I$ and $b \in \text{supp} \mu_i$ we get
\[
\varphi \left( a_i \left( (a_1a_2^m)^n x_0 - \sum_{i=1}^{n} (a_1a_2^m)^i b_1 - b - \sum_{i=0}^{n-1} \sum_{j=1}^{m} a_1^i a_2^{im+j} b_2 - \frac{kb_0}{q_0^n} \right) \right) = 0.
\]
In particular for $i = 1$ and $b = b_1$, we have
\[
\varphi \left( a_1 (a_1a_2^m)^n x_0 - a_1 \sum_{i=1}^{n} (a_1a_2^m)^i b_1 - a_1 b_1 - \sum_{i=0}^{n-1} \sum_{j=1}^{m} a_1^i a_2^{im+j} b_2 - a_1 \frac{kb_0}{q_0^n} \right) = 0.
\]
If we apply Lemma 2.2 with \((c_j, d_j) = (a_2, b_2)\), where \(j = 1, 2, \ldots, m\), to the argument from the previous equality and use the identities
\[
a_1a_2^m \sum_{i=1}^{n} (a_1a_2^m)^i b_1 + a_1a_2^m b_1 = \sum_{i=1}^{n+1} (a_1a_2^m)^i b_1
\]
and
\[
a_2^m \sum_{i=0}^{n-1} \sum_{j=1}^{m} a_1^{i+1} a_2^{im+j} b_2 + \sum_{j=1}^{m} a_2^j b_2 = \sum_{i=0}^{n} \sum_{j=1}^{m} a_1^{i} a_2^{im+j} b_2,
\]
then we get
\[
\varphi \left( (a_1a_2^m)^{n+1} x_0 - \sum_{i=1}^{n+1} (a_1a_2^m)^i b_1 - \sum_{i=0}^{n} \sum_{j=1}^{m} a_1^i a_2^{im+j} b_2 - a_1a_2^m \frac{kb_0}{q_0^{n+1}} \right) = 0.
\]
Since \(a_1a_2^m = q/q_0\), the last equality can be rewritten as
\[
\varphi \left( (a_1a_2^m)^{n+1} x_0 - \sum_{i=1}^{n+1} (a_1a_2^m)^i b_1 - \sum_{i=0}^{n} \sum_{j=1}^{m} a_1^i a_2^{im+j} b_2 - \frac{qkb_0}{q_0^{n+1}} \right) = 0.
\]
Recall that \(a_0 = 1\). If we use Lemma 2.2 with \((c_j, d_j) = (a_0, b_0)\), where \(j = 1, 2, \ldots, l\), to the number from the above equality, then we will get
\[
0 = \varphi \left( (a_1a_2^m)^{n+1} x_0 - \sum_{i=1}^{n+1} (a_1a_2^m)^i b_1 - \sum_{i=0}^{n} \sum_{j=1}^{m} a_1^i a_2^{im+j} b_2 - \frac{qkb_0}{q_0^{n+1}} - lb_0 \right)
\]
\[
= \varphi \left( (a_1a_2^m)^{n+1} x_0 - \sum_{i=1}^{n+1} (a_1a_2^m)^i b_1 - \sum_{i=0}^{n} \sum_{j=1}^{m} a_1^i a_2^{im+j} b_2 - \frac{lq_0^{n+1} + kq b_0}{q_0^{n+1}} \right).
\]
We have chosen the numbers \(k\) and \(l\) in such a way that \(lq_0^{n+1} + kq = s\). Hence
\[
\varphi \left( (a_1a_2^m)^{n+1} x_0 - \sum_{i=1}^{n+1} (a_1a_2^m)^i b_1 - \sum_{i=0}^{n} \sum_{j=1}^{m} a_1^i a_2^{im+j} b_2 - \frac{sb_0}{q_0^{n+1}} \right) = 0,
\]
i.e. \(\varphi(r) = 0\). This equality implies that \(\varphi|_{D_{n+1}} = 0\) since \(r\) was taken arbitrarily. In view of the mathematical induction we have \(\varphi|_{D} = 0\) and the proof is complete in case II.B.

III. We shall consider the last case when \(\text{supp}\mu \subset \mathbb{Z} \times \mathbb{R}\), that is \(A \subseteq \mathbb{Z}\). Recall that \(a_0 = 1\) and \(b_0 \neq 0\). Since \(\mu(((-\infty, 0) \setminus \{-1\}) \times \mathbb{R}) > 0\) we can choose \(i \in I\) such that \(a_i\) is a negative integer different from \(-1\). Without loss of generality we may assume that \(i = 1\). Fix any \(b_1 \in \text{supp}\mu_1\). We define
a sequence of sets \((D_n)_{n\in \mathbb{N}\cup\{0\}}\) setting
\[
D_n := \left\{ e_p \cdots e_1 x_0 - \sum_{i=1}^{p} e_p \cdots e_i f_i - \frac{sb_0}{a_1^n} : p \in \mathbb{N}, s \in \mathbb{Z}, \right. \\
(e_1, f_1), \ldots, (e_p, f_p) \in \text{supp} \mu \text{ and } \exists_{i_0 \in \{1, 2, \ldots, p\}} e_{i_0} = a_1 \left. \right\},
\]
and let
\[
D := \bigcup_{n=0}^{+\infty} D_n.
\]
Note that \(D_n\) contains as a subset the set
\[
\left\{ a_1(x_0 - b_1) - \frac{sb_0}{a_1^n} : s \in \mathbb{Z} \right\}.
\]
We have \(b_0 \neq 0\) and \(a_1^2 > 1\). Lemma 2.3 asserts that the set
\[
\bigcup_{n=0}^{+\infty} \left\{ a_1(x_0 - b_1) - \frac{sb_0}{a_1^n} : s \in \mathbb{Z} \right\}
\]
is dense in \(\mathbb{R}\). Hence also \(D\) is dense. Moreover, now we will show that the sequence \((D_n)_{n\in \mathbb{N}\cup\{0\}}\) has the following properties:

**P1.** If \(r \in D_n\) for some \(n \in \mathbb{N}\) and \(i \in I \setminus \{1\}\), then
\[
a_i(r - b) \in D_n \text{ for every } b \in \text{supp} \mu_i.
\]

**P2.** If \(r \in D_n\) for some \(n \in \mathbb{N}\), then
\[
a_1(r - b) \in D_{n-1} \text{ for every } b \in \text{supp} \mu_1.
\]

Fix \(n \in \mathbb{N}\) and take any \(r \in D_n\). Let \(p \in \mathbb{N}\) and \((e_1, f_1), \ldots, (e_p, f_p) \in \text{supp} \mu\) be such that \(a_1\) is one of \(e_1, \ldots, e_p\) and
\[
r = e_p \cdots e_1 x_0 - \sum_{i=1}^{p} e_p \cdots e_i f_i - \frac{sb_0}{a_1^n}
\]
with some \(s \in \mathbb{Z}\). Take an arbitrary \(i \in I\) and \(b \in \text{supp} \mu_i\). Then \((a_i, b) \in \text{supp} \mu\) and
\[
a_i(r - b) = a_i e_p \cdots e_1 x_0 - a_i \sum_{i=1}^{p} e_p \cdots e_i f_i - a_i b - \frac{a_i sb_0}{a_1^n},
\]
that is
\[
a_i(r - b) = e_{p+1} e_p \cdots e_1 x_0 - \sum_{i=1}^{p+1} e_{p+1} \cdots e_i f_i - \frac{a_i sb_0}{a_1^n},
\]
where \(e_{p+1} := a_i\) and \(f_{p+1} := b\). Since \(A \subseteq \mathbb{Z}\) we have \(a_i s \in \mathbb{Z}\). Consequently, \(a_i(r - b) \in D_n\). If, in addition, \(i = 1\), then \(a_1(r - b) = a_1(r - b) \in D_{n-1}\.\)
Now we are going to show that the function \( \varphi \) is constant on \( D \). As before we will use mathematical induction and start with showing that \( \varphi |_{D_0} = 0 \). Let us recall that

\[
D_0 = \left\{ e_p e_1 x_0 - \sum_{i=1}^{p} e_p e_i f_i - s b_0 : p \in \mathbb{N}, s \in \mathbb{Z}, (e_1, f_1), \ldots, (e_p, f_p) \in \text{supp} \mu \text{ and } \exists i_0 \in \{1,2,\ldots,p\} e_{i_0} = a_1 \right\}.
\]

Fix any \( p \in \mathbb{N}, s \in \mathbb{Z} \) and \( (e_1, f_1), \ldots, (e_p, f_p) \in \text{supp} \mu \) such that \( e_{i_0} = a_1 \) for some \( i_0 \in \{1,2,\ldots,p\} \). In the first step we show the equality

\[
\varphi \left( e_{i_0} e_1 x_0 - \sum_{i=1}^{i_0} e_{i_0} e_i f_i - s b_0 \right) = 0. \quad (2.4)
\]

Applying Lemma 2.2 with \((c_j, d_j) = (e_j, f_j)\), where \( j = 1, 2, \ldots, i_0 - 1 \), to the point \( x_0 \) we get

\[
\varphi \left( e_{i_0-1} e_1 x_0 - \sum_{i=1}^{i_0-1} e_{i_0-1} e_i f_i \right) = 0.
\]

Fix arbitrary \( k \in \mathbb{N} \cup \{0\} \) and remember that \( a_0 = 1 \). If we use Lemma 2.2 with \((c_j, d_j) = (a_0, b_0)\), where \( j = 1, 2, \ldots, k \), to the point from the above equality, then we obtain

\[
\varphi \left( e_{i_0-1} e_1 x_0 - \sum_{i=1}^{i_0-1} e_{i_0-1} e_i f_i - k b_0 \right) = 0.
\]

Putting \( x = e_{i_0-1} e_1 x_0 - \sum_{i=1}^{i_0-1} e_{i_0-1} e_i f_i - k b_0 \) in equality (2.2) we have

\[
\varphi (a_i (x - b)) = 0 \text{ for every } i \in I \text{ and } b \in \text{supp} \mu_i.
\]

If we put \( a_i = e_{i_0} \) and \( b = f_{i_0} \) in the last equality, then we come to

\[
\varphi \left( e_{i_0} e_1 x_0 - \sum_{i=1}^{i_0} e_{i_0} e_i f_i - e_{i_0} k b_0 \right) = 0.
\]

Let \( l \in \mathbb{N} \cup \{0\} \) be arbitrarily fixed. Using Lemma 2.2 with \((c_j, d_j) = (a_0, b_0)\), where \( j = 1, 2, \ldots, l \), to the point from the previous equality we get

\[
\varphi \left( e_{i_0} e_1 x_0 - \sum_{i=1}^{i_0} e_{i_0} e_i f_i - (l + e_{i_0} k) b_0 \right) = 0.
\]

Since \( e_{i_0} \) is a negative integer and \( k, l \in \mathbb{N} \cup \{0\} \), the expression \( l + e_{i_0} k \) can attain any integer value. In particular, we can find \( k, l \in \mathbb{N} \cup \{0\} \) such that \( l + e_{i_0} k = s \). This means that equality (2.4) holds.
We use equality (2.4) to prove that
\[
\varphi \left( e_p e_1 x_0 - \sum_{i=1}^{p} e_p e_i f_i - s b_0 \right) = 0. \tag{2.5}
\]
First note that in the case \( i_0 = p \) equality (2.4) reduces to (2.5). Therefore we assume that \( i_0 < p \). Since \( e_{i_0+1}, \ldots, e_p \in \mathbb{Z} \), we can find \( s \in \mathbb{Z} \) and \( k \in \mathbb{N} \cup \{0\} \) such that \( s = k + e_p e_{i_0+1} \tilde{s} \). If we use Lemma 2.2 with \((c_j, d_j) = (e_{i_0+j}, f_{i_0+j})\)
where \( j = 1, 2, \ldots, p - i_0 \), to the point \( e_{i_0} e_1 x_0 - \sum_{i=1}^{i_0} e_{i_0} e_1 f_i - \tilde{s} b_0 \), then we will get
\[
\varphi \left( e_p e_1 x_0 - \sum_{i=1}^{p} e_p e_i f_i - e_p e_{i_0+1} \tilde{s} b_0 \right) = 0.
\]
Applying Lemma 2.2 with \((c_j, d_j) = (a_0, b_0)\), where \( j = 1, 2, \ldots, k \), to the point from the last equality we come to
\[
\varphi \left( e_p e_1 x_0 - \sum_{i=1}^{p} e_p e_i f_i - (k + e_p e_{i_0+1} \tilde{s}) b_0 \right) = 0.
\]
Putting \( s = k + e_p e_{i_0+1} \tilde{s} \), we get
\[
\varphi \left( e_p e_1 x_0 - \sum_{i=1}^{p} e_p e_i f_i - s b_0 \right) = 0.
\]
Hence \( \varphi|_{D_0} = 0 \).

Now assume that \( \varphi|_{D_n} = 0 \) for some \( n \in \mathbb{N} \cup \{0\} \). We prove that \( \varphi|_{D_{n+1}} = 0 \).
Let \( r \in D_{n+1} \) be fixed and put \( J := I \setminus \{1\} \). Then property P2 asserts that \( a_1 (r - b) \in D_n \) for every \( b \in \text{supp} \mu_1 \). Hence using equality (2.2) and the inductive hypothesis we get
\[
\varphi(r) = \sum_{i \in J} \int_{\mathbb{R}} \varphi \left( a_i (r - b) \right) \mu_i(db) = \sum_{i \in J} \int_{\mathbb{R}} \varphi \left( a_i (r - b) \right) \mu_i(db) + \int_{\mathbb{R}} \varphi \left( a_1 (r - b) \right) \mu_1(db)
\]
\[
= \sum_{i \in J} \int_{\mathbb{R}} \varphi \left( a_i (r - b) \right) \mu_i(db) + 0 = \sum_{i \in J} \int_{\mathbb{R}} \varphi \left( a_i (r - b) \right) \mu_i(db).
\]
The function \( \varphi \) is bounded above by 1. Therefore
\[
\varphi(r) = \sum_{i \in J} \int_{\mathbb{R}} \varphi \left( a_i (r - b) \right) \mu_i(db) \leq \sum_{i \in J} \int_{\mathbb{R}} \mu_i(db) = \sum_{i \in J} \mu_i(\mathbb{R}) = 1 - \mu_1(\mathbb{R}).
\]
If we use equation (2.2) for every \( i \in J \), then we will get
\[
\int_{\mathbb{R}} \varphi(a_i (r - b_1)) \mu_i(db_1) = \int_{\mathbb{R}} \left[ \sum_{j \in J} \int_{\mathbb{R}} \varphi \left( a_j \left( a_i (r - b_1) - b_2 \right) \right) \mu_j(db_2) \right] \mu_i(db_1).
\]
Property P1 asserts that \( a_i(r - b_1) \in D_{n+1} \) for every \( i \in J \) and \( b_1 \in \text{supp} \mu_i \). Moreover, property P2 implies that \( a_1(a_i(r - b_1) - b_2) \in D_n \) for every \( i \in J \) and \((a_i,b_1),(a_1,b_2) \in \text{supp} \mu \). Since \( \varphi|_{D_n} = 0 \), we have

\[
\varphi(a_1(a_i(r - b_1) - b_2)) = 0 \quad \text{for every} \ i \in J \text{ and } (a_i, b_1), (a_1, b_2) \in \text{supp} \mu.
\]

Hence and from the fact that \( \varphi \) is bounded above by 1 we have for all \( i \in I \) the inequalities

\[
\int_R \varphi(a_i(r - b_1)) \mu_i(db_1) = \int_R \left[ \sum_{j \in J} \int_R \varphi(a_j(a_i(r - b_1) - b_2)) \mu_j(db_2) \right] \mu_i(db_1)
\]

\[
= \int_R \left[ \sum_{j \in J} \int_R \varphi(a_j(a_i(r - b_1) - b_2)) \mu_j(db_2) \right] \mu_i(db_1)
\]

\[
\leq \int_R \left[ \sum_{j \in J} \int_R \mu_j(db_2) \right] \mu_i(db_1)
\]

\[
= \int_R \left[ \sum_{j \in J} \mu_j(R) \right] \mu_i(db_1) = \mu_i(R) \sum_{j \in J} \mu_j(R)
\]

\[
= \mu_i(R)(1 - \mu_1(R)).
\]

If we put the above estimations into the equality

\[
\varphi(r) = \sum_{i \in J} \int_R \varphi(a_i(r - b)) \mu_i(db),
\]

then we will get

\[
\varphi(r) \leq (1 - \mu_1(R)) \sum_{i \in J} \mu_i(R) = (1 - \mu_1(R))^2.
\]

In a similar way, using P1 and P2 several times and taking into account that the function \( \varphi \) vanishes on \( D_n \) and the fact that \( \varphi \) satisfies equation (2.2), one can inductively show that

\[
\varphi(r) = \sum_{i_1,\ldots,i_q \in J} \int_{\mathbb{R}^q} \varphi(a_{i_q}(\ldots(a_{i_1}(r - b_1) - b_2)\ldots - b_{i_q})) \mu^{\otimes(i_1\ldots i_q)}(db_1,\ldots,db_q),
\]

where \( q \in \mathbb{N} \) and \( \mu^{\otimes(i_1\ldots i_q)} \) denotes the product of \( \mu_{i_1},\ldots,\mu_{i_q} \). Therefore, since all values of \( \varphi \) lie in \([0,1]\), we have

\[
\varphi(r) \leq (1 - \mu_1(R))^q \quad \text{for every} \ q \in \mathbb{N},
\]

and thus \( \varphi(r) = 0 \) because of the condition \( \mu_1(R) \in (0,1) \). Consequently, we get \( \varphi(x) = 0 \) for every \( x \in D_{n+1} \). Summarizing we see that \( \varphi \) vanishes on \( D \). \( \square \)
Theorem 2.4 may be reformulated also in the language of random variables because of the equivalence between equations (1.1) and (1.2).

**Theorem 2.6.** If \( P(\alpha \in (-\infty, 0) \setminus \{-1\}) > 0 \) and there exists \( b \in \mathbb{R} \setminus \{0\} \) such that \( P((\alpha, \beta) \in U) > 0 \) for each open neighborhood \( U \) of \((1, b)\), then every bounded continuous solution of equation (1.2) attaining its global extremum is constant.

**Remark 2.7.** The assertion of Theorem 2.4 is false when \( \mu(\{-1, 1\} \times \mathbb{R}) = 1 \). This follows from [4, Theorem 2.3].

The condition \((1, b) \in \text{supp } \mu\), where \( b \neq 0\), is not satisfied for all measures. Thus, we are going to prove the next theorem giving another condition under which every bounded continuous solution of the archetypal equation attaining the global extremum is constant. We start with a very simple fact.

**Lemma 2.8.** Let \( a \in (-1, 1) \setminus \{0\} \) and \( t \in (0, +\infty) \). If \((u_n)_{n \in \mathbb{N} \cup \{0\}} \) is a sequence of negative numbers, then the set

\[ +\infty \bigcup_{n=1}^{+\infty} \{u_n + a^n kt : k \in \mathbb{N} \cup \{0\}\} \]

is dense in the positive half line.

**Proof.** Let \( x, \varepsilon \in (0, +\infty) \) be fixed. Choose \( n_0 \in \mathbb{N} \) such that \( a^{2n_0} t < \varepsilon \) and take any \( n \geq n_0 \). Note that \( a^{2n} > 0 \), thus

\[ (0, +\infty) \subset \bigcup_{k=0}^{+\infty} [u_{2n} + a^{2n} kt, u_{2n} + a^{2n} (k+1) t]. \]

We can find \( k_0 \in \mathbb{N} \cup \{0\} \) such that \( x \in [u_{2n} + a^{2n} k_0 t, u_{2n} + a^{2n} (k_0 +1) t] \). In the end, observe that the length of this interval is less than \( \varepsilon \). \( \square \)

**Theorem 2.9.** If \( \mu((-\infty, 0) \times \mathbb{R}) > 0 \) and there exist \((a_1, b_1), \ldots, (a_s, b_s)\) from \( \text{supp } \mu \) such that \( \min\{|a_1|, \ldots, |a_s|\} < 1 \), \( a_1 \cdot \ldots \cdot a_s = -1 \) and

\[ \sum_{i=1}^{2s} a_{\sigma(2s)} \cdot \ldots \cdot a_{\sigma(i)} b_{\sigma(i)} \neq 0, \]  

for some integer \( s \geq 2 \) and \( \sigma : \{1, 2, \ldots, 2s\} \rightarrow \{1, 2, \ldots, s\} \) which takes each value exactly twice, then every continuous solution \( \varphi : \mathbb{R} \rightarrow \mathbb{R} \) of equation (1.1) attaining the global extremum is constant.

**Proof.** We may assume without loss of generality that \( \inf \varphi(\mathbb{R}) = 0 \) and there exists \( x_0 \in \mathbb{R} \) such that \( \varphi(x_0) = 0 \). Observe that the assumptions imposed on \( a_1, \ldots, a_s \) and \( \sigma \) give

\[ a_{\sigma(1)} \cdot \ldots \cdot a_{\sigma(2s)} = (a_1 \cdot \ldots \cdot a_s)^2 = (-1)^2 = 1. \]
If we apply Lemma 2.2 with \((c_i, d_i) = (a_{\sigma(i)}, b_{\sigma(i)})\) for \(i = 1, \ldots, 2s\) to the point \(x_0\), we will get
\[
\varphi \left( a_{\sigma(1)} \cdot \ldots \cdot a_{\sigma(2s)} x_0 - \sum_{i=1}^{2s} a_{\sigma(2s)} \cdot \ldots \cdot a_{\sigma(i)} b_{\sigma(i)} \right) = \varphi \left( x_0 - \sum_{i=1}^{2s} a_{\sigma(2s)} \cdot \ldots \cdot a_{\sigma(i)} b_{\sigma(i)} \right) = 0.
\]
Denote \(-\sum_{i=1}^{2s} a_{\sigma(2s)} \cdot \ldots \cdot a_{\sigma(i)} b_{\sigma(i)}\) by \(t\) for simplicity. Then the last equality can be rewritten as
\[
\varphi(x_0 + t) = 0.
\]
If we again use Lemma 2.2 with \((c_i, d_i) = (a_{\sigma(i)}, b_{\sigma(i)})\) for \(i = 1, \ldots, 2s\) to the point \(x_0 + t\), then we will get \(\varphi(x_0 + 2t) = 0\). By the induction one can prove that
\[
\varphi(x_0 + kt) = 0 \quad \text{for every} \quad k \in \mathbb{N} \cup \{0\}. \tag{2.7}
\]
Now fix any \(k \in \mathbb{N} \cup \{0\}\). Using Lemma 2.2 with \((c_i, d_i) = (a_i, b_i)\) for every \(i = 1, 2, \ldots, s\) to the point \(x_0 + kt\), we come to
\[
\varphi \left( a_s \cdot \ldots \cdot a_1 (x_0 + kt) - \sum_{j=1}^{s} a_j \cdot \ldots \cdot a_1 b_1 \right) = \varphi \left( -x_0 - kt - \sum_{j=1}^{s} a_j \cdot \ldots \cdot a_1 b_1 \right) = 0
\]
since \(a_1 \cdot \ldots \cdot a_s = -1\). Therefore we have
\[
\varphi(y_0 - kt) = 0 \quad \text{for all} \quad k \in \mathbb{N} \cup \{0\}, \tag{2.8}
\]
where \(y_0 := -x_0 - \sum_{j=1}^{s} a_s \ldots a_1 b_1\).

Without loss of generality we may assume that \(|a_1| < 1\). Let \(k \in \mathbb{N} \cup \{0\}\) and \(n \in \mathbb{N}\) be taken arbitrarily. If we use Lemma 2.2 with \((c_i, d_i) = (a_1, b_1)\) for every \(i = 1, 2, \ldots, n\) to the points \(x_0 + kt\) and \(y_0 - kt\), then we obtain the equalities
\[
\varphi \left( a_1^n x_0 - \sum_{j=1}^{n} a_1^j b_1 + a_1^n kt \right) = 0 \tag{2.9}
\]
and
\[
\varphi \left( a_1^n y_0 - \sum_{j=1}^{n} a_1^j b_1 - a_1^n kt \right) = 0, \tag{2.10}
\]
respectively.

We know that \(t \neq 0\), that is either positive, or negative. We consider the first case. Conditions (2.7) and (2.8) imply that the set of zeros of the function \(\varphi\) is unbounded both from above and from below. Therefore for every \(n \in \mathbb{N}\) we can choose a zero \(u_n \in \mathbb{R}\) of the function \(\varphi\) such that
\[
a_1^n u_n - \sum_{j=1}^{n} a_1^j b_1 < 0.
\]
We define also a sequence \((v_n)_{n\in\mathbb{N}}\) of zeros of the function \(\varphi\) fulfilling the opposite inequalities

\[
a_1^n \left( -v_n - \sum_{i=1}^{s} a_s \ldots a_i b_i \right) - \sum_{j=1}^{n} a_j b_1 > 0 \text{ for every } n \in \mathbb{N}.
\]

Equalities (2.9) and (2.10) imply that for every \(n \in \mathbb{N}\) and \(k \in \mathbb{N} \cup \{0\}\) we have

\[
\varphi \left( a_1^n u_n - \sum_{j=1}^{n} a_j b_1 + a_1^n k t \right) = 0
\]

and

\[
\varphi \left( a_1^n \left( -v_n - \sum_{i=1}^{s} a_s \ldots a_i b_i \right) - \sum_{j=1}^{n} a_j b_1 - a_1^n k t \right) = 0.
\]

Put

\[
E := \bigcup_{n=1}^{+\infty} \left\{ a_1^n u_n - \sum_{j=1}^{n} a_j b_1 + a_1^n k t : k \in \mathbb{N} \cup \{0\} \right\}
\]

and

\[
F := \bigcup_{n=1}^{+\infty} \left\{ a_1^n \left( -v_n - \sum_{i=1}^{s} a_s \ldots a_i b_i \right) - \sum_{j=1}^{n} a_j b_1 - a_1^n k t : k \in \mathbb{N} \cup \{0\} \right\}.
\]

Then \(\varphi|_{E \cup F} = 0\). Lemma 2.8 asserts that \(E\) and \(F\) are dense in \((0, +\infty)\). Hence \(E \cup F\) is dense in \(\mathbb{R}\), and thus \(\varphi\) is constant. If \(t\) is negative, the proof is similar and we omit it. \(\square\)

If \(s = 2\) condition (2.6) reduces to a simpler form which is easy to check.

**Corollary 2.10.** Assume that \(\mu \left( (-\infty, 0) \times \mathbb{R} \right) > 0\) and there exist \((a_1, b_1), (a_2, b_2)\) from \(\text{supp} \mu\) such that \(|a_1| \neq 1, a_1 a_2 = -1\) and

\[
b_2 \neq \frac{a_1^2 + a_1}{a_1 - 1} b_1.
\]

Then every continuous solution \(\varphi : \mathbb{R} \to \mathbb{R}\) of equation (1.1) attaining the global extremum is constant.

**Proof.** We shall check that all assumptions of Theorem 2.9 are satisfied. Obviously conditions \(|a_1| \neq 1\) and \(a_1 a_2 = -1\) imply that either \(|a_1| < 1\) or \(|a_2| < 1\). It remains to check (2.6). We can treat \(\sigma\) as a sequence \((\sigma(1), \sigma(2), \sigma(3), \sigma(4))\)
of digits 1 and 2, each of which appears twice. We will see that condition (2.6) holds if \( \sigma = (1, 1, 2, 2) \). Putting equality \( a_2 = -\frac{1}{a_1} \) into the sum

\[
\sum_{i=1}^{2s} a_{\sigma(2s)} \cdot \ldots \cdot a_{\sigma(i)} b_{\sigma(i)},
\]

we get

\[
a_1^2 a_2 b_1 + a_1 a_2^2 b_1 + a_2^2 b_2 + a_2 b_2 = b_1 + \frac{1}{a_1} b_1 + \frac{1}{a_2} b_2 - \frac{1}{a_1} b_2.
\]

The above expression takes value 0 if and only if

\[
\left(1 + \frac{1}{a_1}\right) b_1 = \left(\frac{1}{a_1} - \frac{1}{a_2}\right) b_2,
\]

that is

\[
b_2 = \frac{a_2^2 + a_1}{a_1 - 1} b_1.
\]

Since we assumed that \( b_2 \neq \frac{a_2^2 + a_1}{a_1 - 1} b_1 \), condition (2.6) is satisfied. \( \square \)

Unfortunately the class of measures from Theorems 2.4 and 2.9 still do not cover all possibilities. Consider the following

Example. Let \( \mu \) be a probability measure on the plane \( \mathbb{R}^2 \) such that \( \text{supp} \mu = \{(-2, 1), (2, 2)\} \). Then we cannot use Theorem 2.4 since there is no point of the form \((1, b)\) with some \( b \neq 0 \) in \( \text{supp} \mu \). We cannot use Theorem 2.9 either as \( \text{supp} \mu \) does not contain a point of the form \((a, b) \in \mathbb{R}^2 \) with \(|a| < 1\).

3. The asymptotics of solutions

In this part we study the asymptotic behaviour of bounded continuous solutions of (1.1) which do not necessarily attain the global extremes.

Theorem 3.1. Assume that \( \mu \left(\left(\left[(-\infty, 0) \setminus \{-1\}\right) \times \mathbb{R}\right) > 0 \right. \) and there exists \( b \in \mathbb{R} \setminus \{0\} \) such that \((1, b) \in \text{supp} \mu \). Let \( \varphi : \mathbb{R} \rightarrow \mathbb{R} \) be a bounded continuous solution of (1.1). Then

\[
\liminf_{x \to -\infty} \varphi(x) = \liminf_{x \to +\infty} \varphi(x) = \inf \varphi(\mathbb{R})
\]

and

\[
\limsup_{x \to -\infty} \varphi(x) = \limsup_{x \to +\infty} \varphi(x) = \sup \varphi(\mathbb{R}).
\]
Proof. We will show equalities (3.1) only. Choose a sequence \((x_n)_{n \in \mathbb{N}}\) of reals such that
\[
\varphi(x_n) \to \inf \varphi(\mathbb{R}).
\]
If it is bounded, then one can find its subsequence \((y_n)_{n \in \mathbb{N}}\) which is convergent to some \(x_0 \in \mathbb{R}\). Then, by the continuity of \(\varphi\), we have \(\varphi(x_0) = \inf \varphi(\mathbb{R})\). Hence, by Theorem 2.4, we know that \(\varphi\) is constant and equalities (3.1) hold. So we may assume that \((x_n)_{n \in \mathbb{N}}\) is unbounded. Then we can choose a subsequence \((y_n)_{n \in \mathbb{N}}\) such that either \(y_n \to -\infty\), or \(y_n \to +\infty\). Consider, for instance, the first possibility. Then
\[
\lim_{n \to +\infty} \varphi(y_n) = \inf \varphi(\mathbb{R}),
\]
and thus
\[
\lim_{x \to -\infty} \varphi(x) = \inf \varphi(\mathbb{R}).
\]
Since, in view of Theorem 4.2 from [3], we have
\[
\lim_{x \to -\infty} \varphi(x) = \lim_{x \to +\infty} \varphi(x),
\]
we come to (3.1).

From this theorem the following result can be immediately deduced.

Corollary 3.2. Assume that \(\mu(((-\infty, 0) \setminus \{-1\}) \times \mathbb{R}) > 0\) and there exists \(b \in \mathbb{R} \setminus \{0\}\) such that \((1, b) \in \text{supp} \mu\). Let \(\varphi : \mathbb{R} \to \mathbb{R}\) be a bounded continuous solution of (1.1). If at least one of the limits \(\lim_{x \to -\infty} \varphi(x)\) and \(\lim_{x \to +\infty} \varphi(x)\) exists, then \(\varphi\) is constant.

We also have the analogous results generated by Theorem 2.9.

Theorem 3.3. Assume that \(\mu(((-\infty, 0) \times \mathbb{R}) > 0\) and the set \(\text{supp} \mu\) contains \((a_1, b_1), \ldots, (a_s, b_s)\) such that \(\min\{|a_1|, \ldots, |a_s|\} < 1, a_1 \cdots a_s = -1\) and condition (2.6) is satisfied for some integer \(s \geq 2\) and \(\sigma : \{1, 2, \ldots, 2s\} \to \{1, 2, \ldots, s\}\) which takes value exactly twice. Let \(\varphi : \mathbb{R} \to \mathbb{R}\) be a bounded continuous solution of (1.1). Then
\[
\lim_{x \to -\infty} \inf \varphi(x) = \lim_{x \to +\infty} \inf \varphi(x) = \inf \varphi(\mathbb{R})
\]
and
\[
\lim_{x \to -\infty} \sup \varphi(x) = \lim_{x \to +\infty} \sup \varphi(x) = \sup \varphi(\mathbb{R}).
\]

Corollary 3.4. Assume that \(\mu(((-\infty, 0) \times \mathbb{R}) > 0\) and the set \(\text{supp} \mu\) contains \((a_1, b_1), \ldots, (a_s, b_s)\) such that \(\min\{|a_1|, \ldots, |a_s|\} < 1, a_1 \cdots a_s = -1\) and condition (2.6) is satisfied for some integer \(s \geq 2\) and \(\sigma : \{1, 2, \ldots, 2s\} \to \{1, 2, \ldots, s\}\) which takes value exactly twice. Let \(\varphi : \mathbb{R} \to \mathbb{R}\) be a bounded continuous solution of (1.1). If at least one of the limits \(\lim_{x \to -\infty} \varphi(x)\) and \(\lim_{x \to +\infty} \varphi(x)\) exists, then \(\varphi\) is constant.
The above corollaries can be compared with a similar theorem by Bogachev, Derfel and Molchanov (see [3, Theorem 4.3]).

**Theorem BDM** Assume that the measure $\mu$ fulfills the conditions: $\mu((−∞,0)×\mathbb{R}) > 0$, $\mu(\{0\}×\mathbb{R}) = 0$, $\mu(\{(a,b)\in\mathbb{R}^2 : a(c-b) = c\}) < 1$ for all $c \in \mathbb{R}$ and $\mu(\{-1,1\}×\mathbb{R}) < 1$. Assume that $K \in (0, +\infty)$ and $\int_{\mathbb{R}^2} \ln(\max(|b|, 1))\mu(da, db) < +\infty$. Let $\varphi : \mathbb{R} \to \mathbb{R}$ be a bounded solution of equation (1.1). If at least one of the limits $\lim_{x \to -\infty} \varphi(x)$ and $\lim_{x \to +\infty} \varphi(x)$ exists, then $\varphi$ is constant.

The below examples show that the above results are not comparable: none of them implies the other.

**Example.** Assume that $\mu(\{(1,1)\}) = 1/2$ and

$$\mu\left(\{(−e^{n},0)\}\right) = \frac{1}{2^n} \text{ for } n = 2, 3, \ldots$$

Note that

$$K = \frac{1}{2} \ln |1| + \sum_{n=2}^{+\infty} \frac{1}{2^n} \ln |−e^{2^n}| = \sum_{n=2}^{+\infty} 1 = +\infty.$$ 

Moreover $\mu((−∞,−1)∪(−1,0)×\mathbb{R}) = 1/2$. In this case Theorem BDM cannot be used since $K = +\infty$ but Corollary 3.2 can be applied because of the inequalities $\mu((−∞,−1)∪(−1,0)×\mathbb{R}) > 0$ and $\mu(\{(1,1)\}) > 0$; the second inequality is sufficient since the measure $\mu$ is purely atomic. Thus each bounded continuous solution $\varphi : \mathbb{R} \to \mathbb{R}$ of the equation

$$\varphi(x) = \frac{1}{2}\varphi(x-1) + \sum_{n=2}^{+\infty} \frac{1}{2^n}\varphi(−e^{2^n}x)$$

having at least one of the limits $\lim_{x \to -\infty} \varphi(x)$ and $\lim_{x \to +\infty} \varphi(x)$ is constant.

If we change the above example only in one place, we can apply neither Corollaries 3.2 and 3.4, nor Theorem BDM.

**Example.** Assume that $\mu(\{(e,1)\}) = 1/2$ and

$$\mu\left(\{(−e^{2^n},0)\}\right) = \frac{1}{2^n} \text{ for } n = 2, 3, \ldots$$

For such a measure $\mu$ we cannot use Corollary 3.2 since there is no (for a measure defined like that) $b \in \mathbb{R} \setminus \{0\}$ such that $\mu(\{(1,b)\}) > 0$. Further, observe that if $\mu(\{(a,b)\}) > 0$, then $|a| > 1$. Therefore we cannot apply Corollary 3.4 in this example. Theorem BDM cannot be used here either for the same reason as in the previous example. We know nothing about non-constant bounded continuous solutions $\varphi : \mathbb{R} \to \mathbb{R}$ of the equation

$$\varphi(x) = \frac{1}{2}\varphi(ex-e) + \sum_{n=2}^{+\infty} \frac{1}{2^n}\varphi(−e^{2^n}x).$$
In the last example Theorem BDM can be applied but Corollaries 3.2 and 3.4 cannot.

**Example.** Assume that $\mu((-1, 1)) = \mu((-e, 0)) = 1/2$. All assumptions from Theorem BDM are satisfied. Indeed

$$K = \frac{1}{2} \ln | -1 | + \frac{1}{2} \ln | -e | = \frac{1}{2} < +\infty$$

and

$$\int\int_{\mathbb{R}^2} \ln(\max(|b|, 1))\mu(da, db)$$

$$= \frac{1}{2} \ln(\max(|1|, 1)) + \frac{1}{2} \ln(\max(|e|, 1)) = \frac{1}{2} < +\infty.$$  

Corollaries 3.2 and 3.4 cannot be used here for the same reasons as in the previous example. Therefore, in view of Theorem BDM, every bounded continuous solution $\varphi : \mathbb{R} \to \mathbb{R}$ of the equation

$$\varphi(x) = \frac{1}{2} \varphi(-x - 1) + \frac{1}{2} \varphi(-ex)$$

which has at least one of the limits $\lim_{x \to -\infty} \varphi(x)$ and $\lim_{x \to +\infty} \varphi(x)$ must be constant.

In conclusion, the presented theorems show that non-constant solutions of the archetypal equation in the case $\mu((-\infty, 0) \times \mathbb{R}) > 0$ have to be oscillating functions. The question of the existence of bounded continuous solutions, which are not constant, is still an open problem.
