ABSTRACT. In this paper, we study the model-checking and parameter synthesis problems of the logic TCTL over discrete-timed automata where parameters are allowed both in the model (timed automaton) and in the property (temporal formula). Our results are as follows. On the negative side, we show that the model-checking problem of TCTL extended with parameters is undecidable over discrete-timed automata with only one parametric clock. The undecidability result needs equality in the logic. On the positive side, we show that the model-checking and the parameter synthesis problems become decidable for a fragment of the logic where equality is not allowed. Our method is based on automata theoretic principles and an extension of our method to express durations of runs in timed automata using Presburger arithmetic.

1. INTRODUCTION

In this paper, we further investigate the model-checking problem of real-time formalisms with parameters. In recent works, parametric real-time model-checking problems have been studied by several authors.

Alur et al study in [2] the analysis of discrete- and dense-timed automata where clocks are compared to parameters. For this class of parametric timed automata, they focus on the emptiness problem: are there concrete values for the parameters so that the automaton has an accepting run? They show that when only one clock is compared to parameters, the emptiness problem is decidable. But this problem becomes undecidable when three clocks are compared to parameters. Hune et al study in [9] a subclass of parametric dense-timed

2000 ACM Subject Classification: F.1.1.

Key words and phrases: Real-time, timed automata, timed temporal logics, parameters, decidability.

The authors mention the case of two clocks as an open problem.
automata (L/U automata) such that each parameter occurs either as a lower bound or as an upper bound.

Wang in [12, 13], Emerson et al in [8], Alur et al in [3] and the authors of this paper in [5] study the introduction of parameters in temporal logics. The model-checking problem for TCTL extended with parameters over discrete- and dense-timed automata (without parameters) is decidable. On the other hand, only a fragment of LTL extended with parameters is decidable.

Unfortunately, in all those previous works, the parameters are only in the model (expressed as a timed automaton) or only in the property (expressed as a temporal logic formula). Nevertheless, when expressing a temporal property of a parametric system, it is natural to refer in the temporal formula to the parameters used in the system.

In this paper, we study the model-checking problem of the logic TCTL extended with parameters over the runs of a discrete-timed automaton with one parametric clock. To the best of our knowledge, this is the first work that studies the model-checking and parameter synthesis problems with parameters both in the model and in the property. We restrict to one parametric clock since the emptiness problem for discrete-time automata with three parametric clocks is already undecidable (see above, [2]). The case of dense-timed automata with one parametric clock is not investigated in this paper.

Let us illustrate the kind of properties that we can express with a parametric temporal logic over a parametric timed automaton. The automaton $A$ of Figure 1 is a discrete-timed automaton with one clock $x$ and two parameters $\theta_1$ and $\theta_2$. Here we explicitly model the elapse of time by transitions labeled by 0 or 1. State $q_0$ is labeled with atomic proposition $\sigma$ and in all other states this proposition is false. The possible runs of this automaton starting at $q_0$ are as follows. The control instantaneously leaves $q_0$ and goes through $q_1, q_2, q_3$ to come back in $q_0$, the time spent in this cycle is constrained by the parameters $\theta_1$ and $\theta_2$. In fact, the control has to leave $q_1$ at most $\theta_1$ time units after entering it and the control has to stay exactly $\theta_2$ time units in state $q_2$. To express properties of those behaviors, we use TCTL logic augmented with parameters. Let us consider the next three formulae for configuration $(q_0, 0)$, i.e. the control is in state $q_0$ and clock $x$ has value 0:

(i) $\forall \Box (\sigma \rightarrow \forall \diamond x \leq \theta_2 \sigma)$

(ii) $\forall \theta_1 \forall \theta_2 \cdot (\theta_2 \leq \theta_1 \rightarrow \forall \Box (\sigma \rightarrow \forall \diamond x \leq 2\theta_1 + 2 \sigma))$

![Figure 1: A parametric timed automaton](image)
The parameter synthesis problem associated to formula (i), asks for which values of $\theta_1, \theta_2$, and $\theta_3$, the formula is true at configuration $(q_0, 0)$. By observing the model and the formula, we can deduce the following constraint on the parameters: $\theta_3 \geq \theta_1 + \theta_2 + 2$. This means that any cycle through the four states has duration bounded by $\theta_1 + \theta_2 + 2$. Formula (ii) formalizes the next question “In all the cases where the value assigned to parameter $\theta_1$ is greater than the value assigned to parameter $\theta_2$, is it true that any cycle has a duration bounded by $2\theta_1 + 2$”. As there is no free parameter in the question, the question has a YES-NO answer. This is a model-checking problem. For formula (ii), the answer is YES in configuration $(q_0, 0)$. Finally, formula (iii) lets parameter $\theta_2$ free and formalizes the question “What are the possible values that can be given to $\theta_2$ such that for any value of $\theta_1 \geq 5$, a cycle through the four states lasts at most $2\theta_1 + 1$ time units”. This is again a parameter synthesis problem and the answer is $\theta_2 \leq 4$.

In this paper, we study the algorithmic treatment of such problems. Our results are as follows. On the negative side, we show that the model-checking problem of TCTL extended with parameters is undecidable over timed automata with only one parametric clock. The undecidability result needs equality in the logic. On the positive side, we show that the model-checking problem becomes decidable and the parameter synthesis problem is solvable for a fragment of the logic where the equality is not allowed. Our algorithm is based on automata theoretic principles and an extension of our method (see [5]) to express durations of runs in a timed automaton using Presburger arithmetic. As a corollary, we obtain the decidability of the emptiness problem for discrete-timed automata with one parametric clock proved by Alur et al in [2]. All the formulae given in the example above are in the decidable fragment.

The paper is organized as follows. In Section 2, we introduce the model of one parametric clock discrete-timed automaton and the parametric extension of TCTL that we consider. In Section 3, we establish the undecidability of the model-checking problem if equality can be used in the logic and we show how to solve the problem algorithmically for a fragment of the logic where equality is not allowed. Proofs of two important propositions introduced in Section 3 are postponed to Section 4. We finish the paper in Section 5 by drawing some conclusions.

2. Parameters Everywhere

In this section, we introduce parameters in the automaton used to model the system as well as in the logic used to specify properties of the system. The automata are parametric timed automata as defined in [2] with a discrete time domain and one parametric clock. The logic is Parametric Timed CTL Logic as defined in [5]. We introduce the problems that we want to solve and we conclude the section with an example.

Notation 2.1. Let $\Theta$ be a fixed finite set of parameters $\theta$ that are shared by the automaton and the logical formulae. A parameter valuation for $\Theta$ is a function $v : \Theta \to \mathbb{N}$ which assigns a natural number to each parameter $\theta \in \Theta$. In the sequel, $\alpha, \beta, \ldots$ mean any linear term $\sum \in I c_i \theta_i + c$, with $c_i, c \in \mathbb{N}$ and $\{\theta_i|i \in I\} \subseteq \Theta$. A parameter valuation $v$ is naturally extended to linear terms by defining $v(c) = c$ for any $c \in \mathbb{N}$. We denote by $x$ the unique parametric clock. The same notation $x$ is used for both the clock and a value of the clock. A guard $g$ is any conjunction of $x \sim \alpha$ with $\sim \in \{=, <, \leq, >, \geq\}$. 

(iii) $\forall \theta_1 \cdot (\theta_1 \geq 5 \rightarrow \forall \Box (\sigma \rightarrow \forall \Diamond < 2\theta_1 + 2\sigma))$
We denote by $G$ the set of guards. Notation $x \models_v g$ means that $x$ satisfies $g$ under valuation $v$. We use notation $\Sigma$ for the set of atomic propositions.

2.1. Parametric Timed Automata. We recall the definition of one parametric clock discrete-timed automata as introduced in [2].

We make the hypothesis that non-parametric clocks have all been suppressed by a technique related to the region construction, see [2] for details.

**Definition 2.2.** A parametric timed automaton $A$ is a tuple $(Q, E, L, l)$, where $Q$ is a finite set of states, $E \subseteq Q \times \{0,1\} \times G \times 2^{(x)} \times Q$ is a finite set of edges, $L : Q \rightarrow 2^{E}$ is a labeling function and $l : Q \rightarrow G$ assigns an invariant $l(q) \in G$ to each state $q$. A configuration of $A$ is a pair $(q, x)$, where $q$ is a state and $x$ is a clock value.

Whenever a parameter valuation $v$ is given, $A$ becomes a usual one-clock timed automaton denoted by $A_v$. We recall the next definitions of transition and run in $A_v$.

**Definition 2.3.** Let $v$ be a parameter valuation. A transition $(q, x) \xrightarrow{\tau} (q', x')$ between two configurations $(q, x)$ and $(q', x')$, with time increment $\tau \in \{0,1\}$, is allowed in $A_v$ if (1) $x \models_v l(q)$ and $x' \models_v l(q')$, (2) there exists an edge $(q, \tau, g, r, q') \in E$ such that $x + \tau \models_v g$ and $x' = 0$ if $r = \{x\}$, $x' = x + \tau$ if $r = \emptyset$.2

A run $\rho = (q_i, x_i)_{i \geq 0}$ of $A_v$ is an infinite sequence of transitions $(q_i, x_i) \xrightarrow{\tau_i} (q_{i+1}, x_{i+1})$ such that $\Sigma \geq 0 \tau_i = \infty$.3 The duration $t = D_\rho(q_i, x_i)$ at configuration $(q_i, x_i)$ of $\rho$ is equal to $t = \Sigma_{0 \leq j < i} \tau_j$. A finite run $\rho$ is a finite sequence of transitions. It is shortly denoted by $(q, x) \leadsto (q', x')$ such that $(q, x)$ (resp. $(q', x')$) is its first (resp. last) configuration. Its duration $D_\rho$ is equal to $D_\rho(q', x')$.

2.2. Parametric Timed CTL Logic. Formulae of Parametric Timed CTL logic, PTCTL for short, are formed by a block of quantifiers over some parameters followed by a quantifier-free temporal formula. They are defined as follows. Notation $\sigma$ means any atomic proposition $\sigma \in \Sigma$ and $\alpha, \beta$ are linear terms as before.

**Definition 2.4.** A PTCTL formula $f$ is of the form

$$f = Q_1 \theta_1 \cdots Q_k \theta_k \varphi$$

such that $k \geq 0$, $\{\theta_1, \ldots, \theta_k\} \subseteq \Theta$, $Q_j \in \{\exists, \forall\}$ for each $j$, $1 \leq j \leq k$, and $\varphi$ is given by the following grammar

$$\varphi ::= \sigma \mid \alpha \sim \beta \mid \neg \varphi \mid \varphi \lor \varphi \mid \exists \varphi \mid \varphi \exists \varphi \mid \varphi \forall \varphi \mid \varphi \forall \varphi \mid \varphi \exists \varphi$$

Note that usual operators $\exists U$ and $\forall U$ are obtained as $\exists U_{\geq 0}$ and $\forall U_{\geq 0}$. We also use the following abbreviations: $\exists \forall_{\sim a} \varphi$ for $\exists U_{\sim a} \varphi$, $\forall \forall_{\sim a} \varphi$ for $\forall U_{\sim a} \varphi$, $\exists \exists_{\sim a} \varphi$ for $\neg \exists \forall_{\neg a} \neg \varphi$, and $\forall \forall_{\neg a} \varphi$ for $\neg \exists \forall_{\sim a} \neg \varphi$.

We use notation QF-PTCTL for the set of quantifier-free formulae $\varphi$ of PTCTL. The set of parameters of $\Theta$ that are free in $f$, that is, not under the scope of a quantifier, is denoted by $\Theta_f$. Thus, for a QF-PTCTL formula $\varphi$, we have $\Theta_\varphi = \Theta$ (recall that $\Theta$ is the set of parameters that appear in the formula and in the automaton).

---

2Note that time increment $\tau$ is first added to $x$, guard $g$ is then tested, and finally $x$ is reset according to $r$.

3Non Zenoness property.
We now give the semantics of PTCTL.

**Definition 2.5.** Let $A$ be a parametric timed automaton and $(q, x)$ be a configuration of $A$. Let $f = Q_1 \theta_1 \cdots Q_k \theta_k$ be a PTCTL formula. Given a parameter valuation $v$ on $\Theta_f$, the satisfaction relation $(q, x) \models_v f$ is defined inductively as follows. If $f = \varphi$, then $(q, x) \models_v \varphi$ according to the following rules:

- $(q, x) \models_v \varphi$ iff there exists a run $\rho = (q_i, x_i)_{i \geq 0}$ in $A^v$ with $(q, x) = (q_0, x_0)$ and $\sigma \in L(q)$.
- $(q, x) \models_v \alpha \sim \beta$ iff there exists a run $\rho = (q_i, x_i)_{i \geq 0}$ in $A^v$ with $(q, x) = (q_0, x_0)$ and $v(\alpha) \sim v(\beta)$.
- $(q, x) \models_v \neg \varphi$ iff $(q, x) \not\models_v \varphi$.
- $(q, x) \models_v \varphi \lor \psi$ iff $(q, x) \models_v \varphi$ or $(q, x) \models_v \psi$.
- $(q, x) \models_v \exists \varphi$ iff there exists a run $\rho = (q_i, x_i)_{i \geq 0}$ in $A^v$ with $(q, x) = (q_0, x_0)$ and $(q_1, x_1) \models_v \varphi$.
- $(q, x) \models_v \varphi \cup \psi$ iff there exists a run $\rho = (q_i, x_i)_{i \geq 0}$ in $A^v$ with $(q, x) = (q_0, x_0)$, there exists $i \geq 0$ such that $D_\rho(q_i, x_i) \sim v(\alpha)$, $(q_i, x_i) \models_v \psi$ and $(q_j, x_j) \models_v \varphi$ for all $j < i$.
- $(q, x) \models_v \varphi \cup \psi$ iff there exists a run $\rho = (q_i, x_i)_{i \geq 0}$ in $A^v$ with $(q, x) = (q_0, x_0)$, there exists $i \geq 0$ such that $D_\rho(q_i, x_i) \sim v(\alpha)$, $(q_i, x_i) \models_v \psi$ and $(q_j, x_j) \models_v \varphi$ for all $j < i$.

If $f = \exists \theta f'$, then $(q, x) \models_v f$ iff there exists $c \in \mathbb{N}$ such that $(q, x) \models_v f'$ where $v'$ is defined on $\Theta_f$ by $v' = v$ on $\Theta_f$ and $v'(\theta) = c$. If $f = \forall \theta f'$, then $(q, x) \models_v f$ iff for all $c \in \mathbb{N}$, $(q, x) \models_v f'$ where $v'$ is defined on $\Theta_f$ by $v' = v$ on $\Theta_f$ and $v'(\theta) = c$.

**2.3. Problems.** The problems that we want to solve in this paper are the following ones. The first problem is the model-checking problem for PTCTL formulae $f$ with no free parameters. In this case, we omit the index by $v$ in the satisfaction relation $(q, x) \models f$ since no parameter (neither in the automaton nor in the formula) has to receive a valuation.

**Problem 2.6.** The model-checking problem is the following. Given a parametric timed automaton $A$ and a PTCTL formula $f$ such that $\Theta_f = \emptyset$, given a configuration $(q, x)$ of $A$, does $(q, x) \models f$ hold?

The second problem is the more general problem of parameter synthesis for PTCTL formulae $f$ such that $\Theta_f$ is any subset of $\Theta$.

**Problem 2.7.** The parameter synthesis problem is the following. Given a parametric timed automaton $A$ and a configuration $(q, x)$ of $A$, given a PTCTL formula $f$, compute a symbolic representation of the set of parameter valuations $v$ on $\Theta_f$ such that $(q, x) \models v f$.

**Example** We consider the example given in the introduction with the parametric timed automaton $A$ of Figure 1 and the two PTCTL formulae respectively equal to

$$f : \forall \theta_1 \forall \theta_2 \cdot (\theta_2 \leq \theta_1 \rightarrow \forall \Box (\sigma \rightarrow \forall \Diamond \leq 2\theta_1 + 2 \sigma))$$

and

$$g : \forall \theta_1 \cdot (\theta_1 \geq 5 \rightarrow \forall \Box (\sigma \rightarrow \forall \Diamond < 2\theta_1 + 2 \sigma)).$$

We verify the existence of a run starting in $(q, x)$ to ensure that time can progress in $A^v$ from that configuration.

For instance this representation could be given in a decidable logical formalism.
Then $\Theta = \{\theta_1, \theta_2\}$, $\Theta_f = \emptyset$ and $\Theta_g = \{\theta_2\}$. The model-checking problem “does $(q_0, 0) \models f$ hold” has a yes answer. The parameter synthesis problem “for which parameter valuations $v$ on $\Theta_g$ does $(q_0, 0) \models v$ $g$ hold” receives the answer $\theta_2 \leq 4$.

2.4. Comments. We end Section 2 by some comments on the definitions and the problems presented above.

(1) We consider timed automata with only one parametric clock for the following reason. In [2], the authors investigate the following emptiness problem, which is a particular case of Problem 2.6: are there concrete values for the parameters so that a parametric timed automaton has an accepting run? They show that the emptiness problem is decidable when there is one parametric clock, that this problem is open for two parametric clocks, and that it becomes undecidable for three parametric clocks. They illustrate the hardness of the two-clock emptiness problem by presenting connections with difficult open problems in logic and automata theory.

Both discrete time and dense time are considered in [2] (see [11] for further results), whereas we only deal with discrete time in this paper.

(2) To solve Problem 2.6 we use the same approach as in our paper [5] where we propose a simple proof of the model-checking problem for PTCTL over timed-automata without parameters. We prove in [5] that the durations of runs starting from a region and ending in another region can be defined by a formula of Presburger arithmetic. It follows that the model-checking problem can be reduced to checking whether some sentence of Presburger arithmetic is true or false.

This approach is different from the one used in [1] when there is no parameter at all. We recall that in [1], an extra clock is added to the timed automaton and the model-checking is solved thanks to a labeling (like for CTL) of the region graph of the augmented automaton. We have not investigated this kind of approach here, because the additional clock would be parametric, leading to two parametric clocks inside the automaton.

(3) Linear terms $\alpha$ are present in the definition of parametric timed automata (inside the guards and the invariants) as well as in the definition given for PTCTL. More generally full Presburger arithmetic is present in PTCTL. Alternative restricted definitions could be

- for parametric timed automata: guards and invariants are restricted to conjunctions of $x \sim \theta$, $x \sim c$ (instead of any conjunction of $x \sim \alpha$);
- for PTCTL: the restricted grammar

$$\varphi ::= \sigma \mid \neg \varphi \mid \varphi \lor \varphi \mid \exists U \varphi \mid \varphi \exists U c \varphi \mid \varphi \forall U \sim \theta \varphi \mid \varphi \forall U \sim c \varphi$$

is used instead of the grammar proposed in Definition 2.4.

In this way, the constraints over the parameters are restricted to comparisons with a parameter or with a constant, instead of comparisons with a linear term over parameters.

However we observe in Remark 3.5 below that the undecidability result about the model-checking problem is the same when using Definitions 2.2 and 2.4 or with the above restricted definitions.
3. Decision Problems

In this section, we prove that the model-checking problem is undecidable. The undecidability comes from the use of equality in the operators $\exists U_{=\alpha}$ and $\forall U_{=\alpha}$. Then for a fragment $F$-PTCTL of PTCTL where equality is forbidden, we prove that the model-checking problem becomes decidable. This is the case, where we also positively solve the parameter synthesis problem. Our proofs use Presburger arithmetic and its extension with integer divisibility.

Let us introduce the precise definition of the fragment $F$-PTCTL.

**Definition 3.1.** Notation $F$-PTCTL is used to denote the fragment of PTCTL where equality is forbidden in the operators $\exists U_{=\alpha}$ and $\forall U_{=\alpha}$ and the inequalities $>,\geq$ are forbidden in $\forall U_{=\alpha}$. More precisely, a $F$-PTCTL formula $f$ is of the form $f = Q_1\theta_1 \cdots Q_k\theta_k \varphi$ such that $\varphi$ is given by the grammar

$$\varphi ::= \sigma | \alpha \beta | \neg \varphi | \varphi \lor \varphi | \exists \varphi \exists \varphi | \varphi \exists \varphi_{\geq} \varphi | \varphi \exists \varphi_{>\alpha} \varphi | \varphi \exists \varphi_{>\alpha} \varphi | \varphi \forall U_{<\alpha} \varphi | \varphi \exists U_{<\alpha} \varphi | \varphi \forall U_{<\alpha} \varphi | \varphi \forall U_{=\alpha} \varphi$$

3.1. Undecidability for PTCTL. We prove here that Problem \[2.6\] is undecidable for PTCTL. The proof relies on the undecidability of Presburger arithmetic with divisibility.

*Presburger arithmetic with divisibility* is an extension of Presburger arithmetic with integer divisibility relation. The additional divisibility relation is denoted by $z|z'$ and means “$z$ divides $z'$”. Every formula of Presburger arithmetic with divisibility can be put into normal form:

$$Qz_1Q_2 \cdots Qz_n (-)\phi_1 \star (-)\phi_2 \star \cdots \star (-)\phi_m \quad (3.1)$$

where $\star$ belongs to \{\lor, \land\}, $(\neg)$ means that negation is optional and each $\phi_i$ is one of the following atomic formulae: (i) $z = \alpha$, (ii) $z > \alpha$, (iii) $z|z'$ such that $\alpha$ is a linear term and $z' > 0$. While Presburger arithmetic has a decidable theory, Presburger arithmetic with divisibility is undecidable \[4\].

**Theorem 3.2.** For any sentence $\Phi$ of Presburger arithmetic with divisibility, we can construct a parametric timed automaton $A$, a configuration $(q, x_0)$ and a PTCTL formula $f$ such that $\Phi$ is true iff the answer to the model-checking problem $(q, x_0) \models f$ for $A$ is yes.

Proof. Let us make the assumption that the sentence $\Phi$ is in normal form \(3.1\). We are going to construct a PTCTL formula $f$ and a parametric timed automaton $A$. The set $\Theta$ of parameters is equal to the set of all the variables used in $\Phi$.

For each subformula $\phi_i$ of the form $z = \alpha$ or $z > \alpha$, we define the PTCTL formula $\hat{\phi}_i$ equal to $\phi_i$. For each subformula $\phi_i$ of the form $z|z'$, we construct the next parametric timed automaton $A_{\phi_i}$ and PTCTL formula $\hat{\phi}_i$. The automaton $A_{\phi_i}$ is given in Figure\[2\]. We label the unique initial state $i_1$ of this automaton by $\sigma_1^1$ and the unique final state $f_1$ by $\sigma_2^1$. It is easy to see that there is a run $\rho$ from the initial configuration $(i_1, 0)$ to the final configuration $(f_1, z)$ with duration $D_\rho$ iff $z|D_\rho$. For formula $\hat{\phi}_i$, we take $\sigma_1^1 \land \exists Q_{z = \sigma_2^1}$.

\[6\]In the preliminary version \[6\] of this paper, we considered a fragment of PTCTL that is larger than F-PTCTL. The grammar of the proposed fragment was equal to the grammar proposed in Definition \[3.1\] extended with $\varphi \forall U_{>\alpha} \varphi$ and $\varphi \forall U_{>\alpha} \varphi$. We have found a mistake in the proof of the decidability of the model-checking for this fragment.
Figure 2: Automaton for $z | z'$

Now we construct formula $f$ as follows

$$f : Qz_1 Qz_2 \cdots Qz_n (\neg) \hat{\phi}_1 * (\neg) \hat{\phi}_2 \cdots * (\neg) \hat{\phi}_m.$$  

We construct the automaton $A$ by first taking the union of all the previous automata $A_{\hat{\phi}_l}$ (introduced for the divisibility subformulae). We then merge their initial states into a unique state of $A$ that we call $q$. The label $L(q)$ of $q$ is the union of the labels $\sigma^1_l$. Finally, we add a new state $q'$ to $A$ and an edge $(f_l, 0, \top, \emptyset, q')$ from any final state $f_l$ of $A_{\hat{\phi}_l}$ to state $q'$ labeled with $\tau = 0$ and without any guard and reset. To complete the construction, we add a self-loop $(q', 1, \top, \emptyset, q')$ on $q'$ that allows time to progress.

It is easy to see that given $A$, we have $(q, 0) \models f \Phi$ iff $\Phi$ is true.

As a direct consequence of Theorem 3.2, we have:

**Corollary 3.3.** The model-checking problem for PTCTL is undecidable.

**Remark 3.4.** In the previous proof, all the proposed PTCTL formulae $\hat{\phi}_l$ only use the subscript $=$ in the operators $\exists U \sim \theta$ and $\forall U \sim \theta$. It follows that the model-checking problem is already undecidable with the grammar

$$\varphi ::= \sigma | \alpha \sim \beta | \neg \varphi | \varphi \lor \varphi | \exists U \varphi | \varphi \exists U = \alpha \varphi | \varphi \forall U = \alpha \varphi$$

instead of the grammar given in Definition 2.3.

**Remark 3.5.** Given a sentence $\Phi$ of Presburger arithmetic with divisibility, we have shown in the proof of Theorem 3.2 how to construct a parametric timed automaton $A$, a configuration $(q, x_0)$ and a PTCTL formula $f$ such that $\Phi$ is true iff the answer to the model-checking problem $(q, x_0) \models f$ for $A$ is yes.

As mentioned in Section 2.4 (see Comment 3), we could consider alternative restricted definitions for parametric timed automata and PTCTL. We say that a parametric timed automaton is **restricted** and that a formula of PTCTL is **restricted** if they respect the restricted definitions given in Comment 3 of Section 2.4.

Let us show that given a sentence $\Phi$ of Presburger arithmetic with divisibility, we can construct a restricted parametric timed automaton $A$, a configuration $(q, x_0)$ and a restricted formula $f$ of PTCTL such that $\Phi$ is true iff the answer to the model-checking problem $(q, x_0) \models f$ for $A$ is yes. The proof is in the same vein as the previous one. The sentence $\Phi$ is supposed to be in normal form like in (3.1) with each subformula $\phi_l$ of the form $z = \alpha$, $z > \alpha$, or $z | z'$. We first treat the case $z = \alpha$ (with hints on the construction with $\alpha = 2\theta + 2$). Instead of defining $\hat{\phi}_l$ equal to $\phi_l$ as in the previous proof, we consider the restricted parametric timed automaton of Figure 3 and the restricted formula $\hat{\phi}_l$ equal
to $\sigma_1^2 \land \exists \phi = \sigma_2^2$. The case $z > \alpha$ is treated similarly: for the example of $z > 2\theta + 1$, the automaton is the one of Figure 3 with an additional loop with label 1 on the rightmost location, and the formula is again equal to $\sigma_1^2 \land \exists \phi = \sigma_2^2$. Finally the case $z | z'$ is treated as in the previous proof since the automaton and the formula that we proposed are both restricted.

It follows that the model-checking problem with the restricted definitions of parametric timed automata and logic PTCTL is still undecidable. Notice that again all the proposed restricted formulae $\phi_t$ only use the equality in the operators $\exists U_{< \theta}$ and $\forall U_{< \theta}$.

3.2. Decidability for F-PTCTL. In this section, we provide solutions to the model-checking problem and the parameter synthesis problem for F-PTCTL. Our approach is as follows. Given a state $q$ and a formula $\varphi$ of QF-F-PTCTL, we construct a Presburger formula $\Delta_{q,\varphi}(x, \Theta)$ with $x$ and all $\theta \in \Theta$ as free variables such that

$$(q, x_0) \models f \varphi \iff \Delta_{q,\varphi}(x_0, \nu(\Theta)) \text{ is true}$$

for any valuation $\nu$ on $\Theta$ and any value $x_0$ of the clock (see Theorem 3.8). Solutions to Problems 2.6 and 2.7 will be obtained as a corollary (see Corollaries 3.11 and 3.12). For instance, the decidability of the model-checking problem will derive from the decidability of Presburger arithmetic. Indeed, if we denote by $Q(\Theta) \varphi$ a F-PTCTL formula $f$ with no free parameters, then to test if $(q, x_0) \models f$ is equivalent to test if the sentence $Q(\Theta)\Delta_{q,\varphi}(x_0, \Theta)$ is true.

**Example** Consider the parametric timed automaton of Figure 1 and the QF-F-PTCTL formula $\varphi$ equal to $\forall \Box (\sigma \rightarrow \forall \Box_{\leq \theta_3} \sigma)$. Then $\Theta = \{\theta_1, \theta_2, \theta_3\}$. Presburger formula $\Delta_{q_0,\varphi}(x, \Theta)$ is here equal to $\theta_1 + \theta_2 + 2 \leq \theta_3$ with no reference to $x$ since it is reset along the edge from $q_0$ to $q_1$. Thus $(q, x_0) \models \varphi$ for any clock value $x_0$ and any valuation $\nu$ such that $\nu(\theta_1) + \nu(\theta_2) + 2 \leq \nu(\theta_3)$. The model-checking problem $(q, x_0) \models \forall \theta_1 \forall \theta_2 \exists \theta_3 \varphi$ has a YES answer for any $x_0$ because the sentence $\forall \theta_1 \forall \theta_2 \exists \theta_3 (\theta_1 + \theta_2 + 2 \leq \theta_3)$ is true in Presburger arithmetic. If clock $x$ was not reset along the edge from $q_0$ to $q_1$, then the formula $\Delta_{q_0,\varphi}(x, \Theta)$ would be equal to $(\theta_1 + \theta_2 + 2 \leq \theta_3) \land (x \leq \theta_1)$ and the above model-checking problem would have a YES answer if $\forall \theta_1 \forall \theta_2 \exists \theta_3 (\theta_1 + \theta_2 + 2 \leq \theta_3) \land (x_0 \leq \theta_1)$, that is $x_0 = 0$.

As indicated by this example, the Presburger formula $\Delta_{q,\varphi}(x, \Theta)$ constructed from the QF-F-PTCTL formula $\varphi$ is a boolean combination of terms of the form $\theta \sim \alpha$ or $x \sim \alpha$ where $\theta$ is a parameter, $x$ is the clock and $\alpha$ is a linear term over parameters. Formula $\Delta_{q,\varphi}(x, \Theta)$ must be seen as a syntactic translation of formula $\varphi$ into Presburger arithmetic. The question “does $(q, x_0) \models f$ hold” with $f = Q(\Theta) \varphi$ is translated into the question “is the

---

Notation QF- has been introduced after Definition 2.4 to mention that $\varphi$ is a quantifier free formula.
Presburger sentence $Q \Theta \Delta_{q,\varphi}(x_0, \Theta)$ true”. At this point only, semantic inconsistencies inside $Q \Theta \Delta_{q,\varphi}(x_0, \Theta)$ are looked for to check if this sentence is true or not.

Our proofs require to work with a set $G$ of guards that is more general than in Notation 2.1.

**Notation 3.6.** Linear terms $\alpha, \beta, \ldots$ are any $\Sigma_i c_i \theta_i + c$, with $c_i, c \in \mathbb{Z}$ (instead of $\mathbb{N}$). Comparison symbol $\sim$ used in expressions like $x \sim \alpha$ and $\alpha \sim \beta$ belongs to the extended set $\{=, <, \leq, >, \geq, \equiv_{a, \leq}, \equiv_{a, \geq}\}$. For any constant $a \in \mathbb{N}^+$, notation $z \equiv_{a, \leq} z'$ means $z \equiv z' \mod a$ and $z \leq z'$. Equivalently, this means that there exists $y \in \mathbb{N}$ such that $z + ay = z'$. Notation $z \equiv_{a, \geq} z'$ means $z \equiv z' \mod a$ and $z \geq z'$.

Any $x \sim \alpha$ is called an $x$-atom, any $\alpha \sim \beta$ is called a $\theta$-atom. An $x$-conjunction is any conjunction of $x$-atoms, and a $\theta$-conjunction is any conjunction of $\theta$-atoms. We denote by $B_{x, \Theta}$ the set of boolean combinations of $x$-atoms and $\theta$-atoms. A *guard* is any element of $B_{x, \Theta}$. Thus the set $G$ of Notation 2.1 is now equal to the set $B_{x, \Theta}$.

From now on, it is supposed that the guards and the invariants appearing in parametric timed automata belong to the generalized set $G = B_{x, \Theta}$. It should be noted that the extension of $\sim$ to $\{=, <, \leq, >, \geq, \equiv_{a, \leq}, \equiv_{a, \geq}\}$ is only valid inside automata, and not inside PTCTL formulae. We shortly call *automaton* any parametric timed automaton $A$.

The next lemma states that any $B_{x, \Theta}$ formula is a Presburger formula. It also states that this formula can be rewritten in a particular form that will be useful later.

**Lemma 3.7.** Any $B_{x, \Theta}$ formula is a Presburger formula. It can be rewritten as a disjunction of conjunctions of $x$-atoms and $\theta$-atoms with $\sim$ limited to $\{=, \leq, \geq, \equiv_{a, \leq}, \equiv_{a, \geq}\}$.

**Proof.** Operators $\equiv_{a, \leq}$ and $\equiv_{a, \geq}$ are easily rewritten in Presburger arithmetic. Even if linear terms $\alpha, \beta, \ldots$ contain constants in $\mathbb{Z}$, any $x \sim \alpha$ and $\alpha \sim \beta$ can also be rewritten in Presburger arithmetic. This shows that any $B_{x, \Theta}$ formula is a Presburger formula.

To rewrite a $B_{x, \Theta}$ formula as described in the lemma, it is first put into disjunctive normal form. Second negation is suppressed in any $\neg(z \sim z')$ as follows. This is done easily for $\sim \in \{<, \leq, >, \geq\}$. Negation $\neg(z = z')$ is replaced by $z < z' \lor z > z'$. Negation $\neg(z \equiv_{a, \leq} z')$ is equivalent to $(z > z') \lor (\bigvee_{0 < b \leq a} z + b \equiv_{a, \leq} z')$. Similarly for $\neg(z \equiv_{a, \geq} z')$. Third all inequalities $z < z'$ and $z > z'$ are replaced respectively by $z \leq z' - 1$ and $z \geq z' + 1$.

Finally this formula is put into disjunctive normal form.

Let us now state our main result.

**Theorem 3.8.** Let $A$ be an automaton and $q$ a state of $A$. Let $\varphi$ be a QF-F-PTCTL. Then there exists a $B_{x, \Theta}$ formula $\Delta_{q,\varphi}(x, \Theta)$ with $x$ and all $\theta \in \Theta$ as free variables such that $(q, x_0) \models_v \varphi$ iff $\Delta_{q,\varphi}(x_0, v(\Theta))$ is true for any valuation $v$ on $\Theta$ and any clock value $x_0$. The construction of formula $\Delta_{q,\varphi}$ is effective.

The proof of Theorem 3.8 is by induction on the way formula $\varphi$ is constructed. Before detailing its proof, we roughly give the main ideas. First, suppose for instance that along a run $\rho = (q_i, x_i)_{i \geq 0}$ of $A^v$ showing that $(q_0, x_0) \models_v \varphi$, some configuration, say $(q_j, x_j)$, needs to satisfy $(q_j, x_j) \models_v \psi$ with $\psi$ a subformula of $\varphi$. The automaton $A$ is modified into $A'$ such that the invariant $I(q_j)$ is augmented by the $B_{x, \Theta}$ formula $\Delta_{q_j, \psi}$ constructed by induction.

---

8Such kind of invariant is allowed in Notation 3.6.
Along the run \( \rho \) seen in the modified automaton \( A' \), the satisfaction relation \( (q_j, x_j) \models_v \psi \) holds automatically thanks to the augmented invariant of \( q_j \). Second, what we also need is a \( B_{x, \Theta} \) formula that expresses the existence of an infinite run starting at a given configuration (for operator \( \exists \square \) for instance) and another one that expresses the existence of a finite run \( \rho \) starting and ending at given configurations such that \( D_\rho \sim v(\alpha) \) (for operator \( \exists U_{\sim \alpha} \) for instance). This is possible by the next two propositions. Their proofs are postponed till Section 4.

**Proposition 3.9.** Let \( A \) be an automaton and \( q \) be a state. Then there exists a \( B_{x, \Theta} \) formula \( \text{Run}_q(x, \Theta) \) such that for any valuation \( v \) and any clock value \( x_0 \),

\[
\text{Run}_q(x_0, v(\Theta)) \text{ is true iff there exists an infinite run in } A^v \text{ starting with } (q, x_0). \quad \text{The construction of } \text{Run}_q(x, \Theta) \text{ is effective.}
\]

**Proposition 3.10.** Let \( A \) be an automaton and \( q, q' \) be two states. Let \( \sim \in \{<, \leq, >, \geq\} \) and \( \alpha \) be a linear term. Then there exists a \( B_{x, \Theta} \) formula \( \text{Duration}_{q,q'}^{\sim \alpha}(x, \Theta) \) such that for any valuation \( v \) and any clock value \( x_0 \),

\[
\text{Duration}_{q,q'}^{\sim \alpha}(x_0, v(\Theta)) \text{ is true iff there exists a finite run } \rho = (q, x_0) \rightsquigarrow (q', \cdot) \text{ in } A^v \text{ with } D_\rho \sim v(\alpha). \quad \text{The construction of } \text{Duration}_{q,q'}^{\sim \alpha}(x, \Theta) \text{ is effective.}
\]

For the proof of Theorem 3.8 instead of the grammar given in Definition 3.1 we prefer to work with the grammar

\[
\varphi ::= \sigma \mid \alpha \sim \beta \mid \neg \varphi \mid \varphi \lor \varphi \mid \exists \varphi \\
\mid \varphi \exists U_{<\alpha} \varphi \mid \varphi \exists U_{\leq \alpha} \varphi \mid \varphi \exists U_{> \alpha} \varphi \mid \varphi \exists U_{\geq \alpha} \varphi \\
\mid \exists \square_{<\alpha} \varphi \mid \exists \square \varphi
\]

This grammar is equivalent because formula \( \varphi \exists U_{\sim \alpha} \psi \) with \( \sim \in \{<, \leq\} \) can be replaced by \( \neg [(\exists \square_{\leq \alpha} \neg \psi) \lor (\neg \psi \exists U_{\sim \alpha} (\neg \varphi \land \neg \psi))] \), formula \( \varphi \exists U \psi \) by \( \neg [(\exists \square \neg \psi) \lor (\neg \psi \exists U (\neg \varphi \land \neg \psi))] \), and formula \( \exists \square_{<\alpha} \varphi \) by \( \exists \square_{<\alpha+1} \varphi \).

It is not difficult to check that the semantics of the new operator \( \exists \square_{<\alpha} \varphi \) is given by

\[
(q, x) \models_v \exists \square_{<\alpha} \varphi \text{ if there exists a run } \rho = (q_i, x_i)_{i \geq 0} \text{ of } A^v \text{ with } (q, x) = (q_0, x_0), \text{ there exists } j \geq 0 \text{ such that } D_\rho(q_j, x_j) \geq v(\alpha) \text{ and } (q_i, x_i) \models_v \varphi \text{ for all } i < j.
\]

**Proof.** (of Theorem 3.8). The proof is by induction on \( \varphi \).

- If \( \varphi = \sigma \), then \( (q, x_0) \models_v \varphi \) iff there exists an infinite run starting with \( (q, x_0) \) and \( \sigma \in L(q) \). Therefore

\[
\Delta_{q, \varphi}(x, \Theta) = \bot \quad \text{if } \sigma \notin L(q) \\
= \text{Run}_q(x, \Theta) \quad \text{otherwise.}
\]

- Similarly, if \( \varphi = \alpha \sim \beta \) with \( \sim \in \{=, <, \leq, >, \geq\} \), then

\[
\Delta_{q, \varphi}(x, \Theta) = (\alpha \sim \beta) \land \text{Run}_q(x, \Theta).
\]

- If \( \varphi = \psi \lor \phi \), then \( \Delta_{q, \varphi} = \Delta_{q, \psi} \lor \Delta_{q, \phi} \).

- If \( \varphi = \neg \psi \), then \( \Delta_{q, \varphi} = \neg \Delta_{q, \psi} \).
Let us treat $\varphi = \exists \bigcirc \psi$. Recall that $(q, x_0) \models_v \exists \bigcirc \psi$ iff there exists a transition $(q, x_0) \xrightarrow{r} (q', x'_0)$ such that $(q', x'_0) \models_v \psi$ and $(q', x'_0)$ is the first configuration of an infinite run $\rho \,^\prime$. Let $(q, q, g, r, q')$ be the edge of $E$ that has lead to the transition $(q, x_0) \xrightarrow{r} (q', x'_0)$. Then (see Definition 2.3), $x'_0 = 0$ if $r = \{x\}$, and $x'_0 = x_0 + \tau$ if $r = \emptyset$. By induction hypothesis, $\Delta_{q', \psi}(x'_0, v(\Theta))$ is true iff $(q', x'_0) \models_v \psi$. The automaton $A$ is modified into an automaton $\overline{A}$ as follows. A copy $\overline{q}$ of $q$ is added to $Q$ such that $L(\overline{q}) = L(q')$, $l(\overline{q}) = l(q') \land \Delta_{q', \psi}(x, \Theta)$. A copy $(\overline{q}, q', r', p)$ is also added for each edge $(q', r', r', g', p)$ leaving $q'$. By Proposition 3.9 applied to $\overline{A}$ and $\tau$, we get a $B_{x, \theta}$ formula Run$_\tau$ such that Run$_\tau(x'_0, v(\Theta))$ is true iff there exists an infinite run in $\overline{A}^v$ starting with $(\overline{q}, x'_0)$. By construction of $\tau$, equivalently there exists an infinite run in $A^v$ starting with $(q, x_0)$ and such that $(q', x'_0) \models_v \psi$. Hence, the expected formula $\Delta_{q, \varphi}(x, \Theta)$ is equal to

$$\Delta_{q, \varphi}(x, \Theta) = \bigvee_{(q, r, g, \{x\} \in E} (l(q) \land \text{Run}_{\tau}(0, \Theta)) \lor \bigvee_{(q, r, g, \{x\} \in E} (l(q) \land \text{Run}_{\tau}(x + r, \Theta)).$$

- The construction of formula $\Delta_{q, \varphi}$ for $\varphi = \exists \bigcirc \psi$ is in the same vein as the previous one. Recall that $(q, x_0) \models_v \varphi$ iff there is an infinite run in $A^v$ with first configuration $(q, x_0)$ such that all its configurations satisfy $\psi$. The automaton $A$ is here modified into $\overline{A}$ as follows. For any state $p \in Q$, $l(p)$ is replaced by $l(p) \land \Delta_{p, \psi}(x, \Theta)$. By Proposition 3.9 applied to $\overline{A}$, we get a formula $\text{Run}_q$ such that $\text{Run}_q(x_0, v(\Theta))$ is true iff there exists an infinite run in $A^v$ starting with $(q, x_0)$ and such that all its configurations satisfy $\psi$. Therefore formula $\Delta_{q, \varphi}(x, \Theta)$ is equal to $\text{Run}_q(x, \Theta)$.

- Let us turn to formula $\varphi = \psi \exists U_{\sim_\alpha} \phi$ with $\sim \in \{<, \leq, >, \geq\}$. We have $(q, x_0) \models_v \varphi$ iff either (1) $(q, x_0) \models_v \phi$, $0 \sim v(\alpha)$ and $(q, x_0)$ is the first configuration of an infinite run, or (2) there exists a finite run $\rho = (q, x_0) \sim (q', x'_0)$ such that $D_\rho \sim v(\alpha)$, $\psi$ is satisfied at every configuration of $\rho$ distinct from $(q', x'_0)$, $\phi$ is satisfied at $(q', x'_0)$ and $(q', x'_0)$ is the first configuration of an infinite run. For any state $p \in Q$, formulae $\Delta_{p, \psi}$ and $\Delta_{p, \phi}$ have been constructed by induction hypothesis. So, in case (1), with the same construction of $\overline{A}$ as done before for operator $\bigcirc$ (with $q, \phi$ instead of $q', \psi$), we have the next formula

$$\text{Run}_q(x, \Theta).$$

Case (2) is more involved. The automaton $A$ is first modified into $\overline{A}$ as for operator $\bigcirc$ (with $q', \phi$ instead of $q', \psi$) to get formula $\text{Run}_{\overline{\tau}}$ such that $\text{Run}_{\overline{\tau}}(x'_0, v(\Theta))$ is true iff there exists an infinite run in $\overline{A}^v$ starting with $(q', x'_0)$ and such that $(q', x'_0) \models_v \phi$. The automaton $A$ is then modified in another automaton $\overline{A}$ in the following way. A copy $q'$ of $q'$ is added to $Q$ as well as a copy of each edge of $E$ entering $q'$ as entering $q'$; we define $L(q') = L(q')$ and $l(q') = l(q') \land \Delta_{p, \psi}(x, \Theta)$. Thanks to Proposition 3.10 applied to $\overline{A}$, we obtain a formula $\text{Duration}_{\sim_\alpha}(x, \Theta)$ expressing the following: $\text{Duration}_{\sim_\alpha}(x_0, v(\Theta))$ is true iff there exists in $\overline{A}^v$ a finite run $\rho = (q, x_0) \sim (q', x'_0)$ with $D_\rho \sim v(\alpha)$. Equivalently there exists in $A^v$ a finite run $\rho = (q, x_0) \sim (q', x'_0)$ with $D_\rho \sim v(\alpha)$ such that $\psi$ is satisfied at every
configuration of \( \rho \) distinct from \((q', x'_0)\), \( \phi \) is satisfied at \((q', x'_0)\) and \((q', x'_0)\) is the first configuration of an infinite run. For case (2), the expected formula is thus the disjunction
\[
\bigvee_{q' \in Q} \text{Duration}^{\sim \alpha}_{q', q}(x, \Theta).
\]
Therefore, putting together cases (1) and (2), formula \( \Delta_{q, \varphi} \) is the disjunction
\[
((0 \sim \alpha) \land \text{Run}_{q}(x, \Theta)) \lor \bigvee_{q' \in Q} \text{Duration}^{\sim \alpha}_{q', q}(x, \Theta).
\]

Finally, let \( \varphi \) be \( \exists \Box <\alpha \psi \). Then \((q, x_0) \models \varphi \) iff there exists a finite run \( \rho = (q, x_0) \sim (q', x') \) such that \( D' \geq v(\alpha) \), \((p, x) \models \psi\) for each configuration \((p, x)\) of \( \rho \) distinct from \((q', x')\) and \((q', x')\) is the first configuration of an infinite run. As done just before in case (2), \( A \) is modified into \( \overline{A} \) except that we use \( \overline{\text{Run}}_{q'} \) instead of \( \text{Run}_{q} \) in the definition of \( I(\overline{q'}) \). By Proposition 3.10, formula \( \Delta_{q, \varphi} \) is equal to
\[
\bigvee_{q' \in Q} \text{Duration}^{\sim \alpha}_{q', q}(x, \Theta).
\]

The proof is completed since all the proposed formulae belong to \( B_{x, \Theta} \) and their construction is effective. \( \square \)

Solutions to the model-checking problem and the parameter synthesis problem are obtained as a corollary of Theorem 3.8.

**Corollary 3.11.** The model-checking problem for F-PTCTL is decidable.

**Proof.** Let \( Q\Theta \varphi \) be a F-PTCTL formula \( f \) with no free parameters. By Theorem 3.8,
\[(q, x_0) \models f \iff Q\Theta \Delta_{q, \varphi}(x_0, \Theta) \text{ is true.} \]
By Lemma 3.7, formula \( Q\Theta \Delta_{q, \varphi}(x_0, \Theta) \) is a Presburger formula. As Presburger arithmetic has a decidable theory and \( Q\Theta \Delta_{q, \varphi}(x_0, \Theta) \) is a Presburger sentence, the model-checking problem is decidable. \( \square \)

The next corollary is straightforward. It states that the parameter synthesis problem is solvable.

**Corollary 3.12.** Let \( A \) be an automaton and \((q, x_0)\) a configuration of \( A \). Let \( \{\theta_1, \ldots, \theta_k\} \subseteq \Theta \) with \( k \geq 0 \) and let \( f = Q_1\theta_1 \cdots Q_k\theta_k \varphi \) be a F-PTCTL formula. Then the Presburger formula \( Q_1\theta_1 \cdots Q_k\theta_k \Delta_{q, \varphi}(x_0, \Theta) \) with free variables in \( \Theta_f \) is an effective characterization of the set of valuations \( v \) on \( \Theta_f \) such that \((q, x_0) \models_v f. \) \( \square \)

Corollary 3.12 has important consequences that we want to detail now. Let us denote by \( V(A, f, q, x_0) \) the set of valuations \( v \) on \( \Theta_f \) such that \((q, x_0) \models_v f \). Let \( \Theta_f \) be equal to \( \{\theta'_1, \ldots, \theta'_l\} \). Presburger arithmetic has an effective quantifier elimination, by adding to the operations \( + \) and \( \leq \) all the congruences \( \equiv \text{mod} a \), \( a \in \mathbb{N}^+ \). It follows the characterization of \( V(A, f, q, x_0) \) given above in Corollary 3.12 by
\[Q_1\theta_1 \cdots Q_k\theta_k \Delta_{q, \varphi}(x, \Theta)\]
can be effectively rewritten without any quantifier. On the other hand, since Presburger arithmetic has a decidable theory, any question formulated in this logic about \( V(A, f, q, x_0) \)
is decidable. For instance, the question “Is the set $V(A, f, q, x_0)$ non empty” is decidable as it is formulated in Presburger arithmetic by
$$\exists \theta'_1 \cdots \exists \theta'_l Q_1 \theta_1 \cdots Q_k \theta_k \Delta_{q,\varphi}(x, \Theta).$$

The question “Does the set $V(A, f, q, x_0)$ contain all the valuations on $\Theta_f$” is also decidable as it can be formulated as
$$\forall \theta'_1 \cdots \forall \theta'_l Q_1 \theta_1 \cdots Q_k \theta_k \Delta_{q,\varphi}(x, \Theta).$$

The question “Is the set $V(A, f, q, x_0)$ finite” is translated into
$$\exists z \forall \theta'_1 \cdots \forall \theta'_l Q_1 \theta_1 \cdots Q_k \theta_k (\Delta_{q,\varphi}(x, \Theta) \Rightarrow \land_i \theta'_i \leq z).$$

And so on.

4. Durations

The aim of this section is to prove Propositions 3.9 and 3.10. This is achieved thanks to a precise description of the possible durations of finite runs in an automaton. Several steps are necessary for this purpose.

In the first subsection, we show that we can work with automata put in some normal form. This normalization allows a simplified presentation of the proofs of the next subsections.

In Subsections 4.2 and 4.3, we restrict to reset-free normalized automata, that is automata in which there is no reset of the clock. For this family of automata, we study the runs of the form $(i, x_0) \leadsto (f, \cdot)$ such that $i \in I, f \in F$ with $I, F$ being two fixed subsets of states, and $x_0$ is a fixed clock value. In Subsection 4.2, a sequence of transformations is performed on the automata such that the $x$-atoms used in the automata are limited to equalities $x = \alpha$. These simplifications lead in Subsection 4.3 to the description by a Presburger formula of the durations $D_{\rho}$ of runs $\rho = (i, x_0) \leadsto (f, \cdot), i \in I, f \in F$.

In the last subsection, we remove the reset-free restriction imposed to the automata and we study in details the durations $D_{\rho}$ of runs $\rho = (q, x_0) \leadsto (q', \cdot)$ between two fixed states $q$ and $q'$. Any such run $\rho$ can be decomposed into a sequence of runs $\rho_j, 1 \leq j \leq k$, according to the reset of the clock, that is the clock is reset at the beginning and the end of $\rho_j$ but not inside of $\rho_j$. The duration $D_{\rho}$ of $\rho$ is thus the sum of the durations $D_{\rho_j}, 1 \leq j \leq k$.

Any $D_{\rho_j}$ falls into durations being studied in Section 4.3. Thanks to this description of any duration $D_{\rho}$ in terms of durations in reset-free automata, we are finally able to prove Propositions 3.9 and 3.10.

In Subsections 4.1, 4.2 and 4.3, we are going to perform a sequence of transformations on the automata $A$ that will preserve the set of runs in $A^v$ for any valuation $v$, in the following sense. During a transformation, state $q$ will possibly be split into several copies $\overline{q}_j$. Runs before and after the splitting can be supposed identical up to a renaming of any $\overline{q}_j$ into $q$.

\footnote{Such an identification of runs is already present in the proof of Theorem 3.8.}
4.1. Normalized Automata. In this subsection, the automata are put in some normal form. The aim of this normalization is a simplified presentation of the proofs in the rest of the paper.

**Definition 4.1.** An automaton $A$ is normalized if

- The guards labeling the edges and used in the invariants are limited to conjunctions of $x$-atoms and $\theta$-atoms with $\sim \in \{=, \leq, \geq, \equiv_{a, \leq}, \equiv_{a, \geq}\}$,
- for any state $q \in Q$, the edges $(p, \tau, g, r, q)$ entering $q$ are all labeled by the same $g$ and the same $r$ (however $\tau$ can vary).

**Proposition 4.2.** Any automaton $A$ can be effectively normalized such that the set of runs in $A^v$ is preserved for any valuation $v$.

**Proof.** Let $g \in B_{x,\theta}$ be a guard. By Lemma 3.7, it can be rewritten as a disjunction of $k$ formulae $\delta_j$, $1 \leq j \leq k$, where each $\delta_j$ is a conjunction of $x$-atoms and $\theta$-atoms with $\sim \in \{=, \leq, \geq, \equiv_{a, \leq}, \equiv_{a, \geq}\}$. If $g$ labels the edge $(q, \tau, g, r, q')$ of $A$, then we modify $A$ by splitting this edge into $k$ edges $(q, \tau, \delta_j, r, q')$, $1 \leq j \leq k$. If $g = l(q)$ for some state $q$, we modify $A$ by splitting $q$ into $k$ states $q_j$, $1 \leq j \leq k$, such that $L(q_j) = L(q)$, $l(q_j) = \delta_j$ and we accordingly split any edge that enters or leaves state $q$. The first condition of Definition 4.1 is therefore satisfied.

For the second condition, the construction is similar. Suppose that there are several edges $(p, \tau, g, r, q)$ entering state $q$ with distinct couples $(g, r)$. Then $q$ is split into several copies (one copy for one couple $(g, r)$) and all the edges entering $q$ are redirected to each copy, according to the couples $(g, r)$. The copies of $q$ have the same $L(q)$ and $l(q)$ as $q$. \qed

4.2. Transformations of Reset-free Automata. In all this subsection, we assume the next hypothesis.

**Hypothesis (\ast)** We assume that $A = (Q, I, F, E, L, l)$ is a reset-free normalized automaton with a set $I \subseteq Q$ of initial states and a set $F \subseteq Q$ of final states. We also assume such that $I \cap F = \emptyset$, no edge enters $i \in I$ and no edge leaves $f \in F$.

**Remark** As $A$ is normalized and reset-free, given a state $q$, all edges $(p, \tau, g, r, q)$ entering $q$ have the same guard $g$ and satisfy $r = \emptyset$. It follows that we can move guard $g$ from these edges to the invariant $l(q)$ of $q$. Indeed $g$ is simply erased from all the edges entering $q$ and added as a conjunction to $l(q)$. By this construction, the set $E$ of edges of $A$ can be rewritten as a subset of $Q \times \{0, 1\} \times Q$, instead of $Q \times \{0, 1\} \times G \times 2^{|x|} \times Q$ (see Definitions 2.2 and 2.3).

On the other hand, as $A$ is normalized, the invariant $l(q)$ of any state $q$ is a conjunction of $x$-atoms and $\theta$-atoms. We can view $l(q)$ as a set of $x$-atoms and $\theta$-atoms (instead of a conjunction) and we will often say that an $x$-atom or a $\theta$-atom belongs to $q$ (instead of $l(q)$) or appears in $q$.

Given a valuation $v$ and a clock value $x_0$, we denote by

$$R(A^v, x_0)$$

the set of runs of $A^v$ of the form $(i, x_0) \leadsto (f, \cdot)$ for some $i \in I$ and $f \in F$. We are going to perform a sequence of transformations on $A$ that will preserve $R(A^v, x_0)$. The aim of these transformations is to simplify the form of the invariants used in the automaton. The invariant $l(q)$ of any state $q \in Q \setminus (I \cup F)$ will be a conjunction of at most one $x$-atom (of
the form \( x = \alpha \) and one \( \theta \)-conjunction. This simplification will be possible mainly because the automaton is reset-free (see Proposition 4.4).

**Definition 4.3.** A reset-free normalized automaton \( A \) is simplified if
- for all \( q \in Q \), the invariant \( I(q) \) is equal to
  \[ I_x(q) \land I_{\theta}(q) \]
such that \( I_x(q) \) is an \( x \)-conjunction and \( I_{\theta}(q) \) is a \( \theta \)-conjunction. Among the \( x \)-atoms \( x \sim \alpha \) of \( I_x(q) \), at most one is an equality \( x = \alpha \). Moreover, if \( q \notin I \cup F \), then \( I_x(q) \) contains no other \( x \)-atom \( x \sim \beta \) with \( \sim \in \{\leq, \geq, \equiv_{a, \leq}, \equiv_{a, \geq}\} \), and if \( q \in I \) (resp. \( q \in F \)), then the other \( x \)-atoms of \( I_x(q) \) are of the form \( x \geq \beta \) (resp. \( x \leq \beta \)).
- for any run \( \rho \in R(A^v, x_0) \), for any \( x \)-atom \( x = \alpha \), there exists at most one configuration \((q', x') \) of \( \rho \) such that \( I_x(q') \) contains \( x = \alpha \).

This definition is illustrated by the next very simple example.

**Example** Consider the simplified automaton \( A \) of Figure 4 with one initial state \( i \) and one final state \( f \). The invariant of state \( p \) has no component \( I_x(p) \) and its \( \theta \)-conjunction \( I_{\theta}(p) \) is limited to the \( \theta \)-atom \( \theta_1 > \theta_2 \). The other states of the automaton has no \( \theta \)-conjunction. They can have at most one \( x \)-atom which is an equality, like state \( q \) containing the equality \( x = \theta_1 \). The initial state \( i \) can have \( x \)-atoms of the form \( x \geq \alpha \) but it has no such \( x \)-atom in this example. The final state \( f \) has the \( x \)-atom \( x \leq \theta_2 \).

**Proposition 4.4.** Any reset-free normalized automaton \( A \) can be effectively simplified such that the set \( R(A^v, x_0) \) is preserved for any valuation \( v \) and any clock value \( x_0 \).

**Proof.** The proof of Proposition 4.4 needs several steps. The transformations described in the proof are based on standard constructions of automata theory. Each of them will preserve \( R(A^v, x_0) \) for any valuation \( v \) and any clock value \( x_0 \). After each transformation, the resulting automaton will be again denoted by \( A \).

In the first step, we are going to suppress in each \( I_x(q) \), for \( q \in Q \), all \( x \)-atoms of the form \( x \equiv_{a, \leq} \alpha \).

First step. \( x \)-atoms \( x \equiv_{a, \leq} \alpha \).

Let us show that any \( x \)-atom \( x \equiv_{a, \leq} \alpha \) belonging to some state \( q \) can be suppressed at the cost of a new \( x \)-atom \( x \leq \alpha \). The idea is the following. If \( \alpha \equiv b \mod a \) for a certain \( b \in \{0, 1, \ldots, a - 1\} \), then \( x \equiv_{a, \leq} \alpha \) if \( x \equiv b \mod a \) and \( x \leq \alpha \).

---

12 As \( \alpha \) is a linear term over the parameters, the value \( b \) such that \( \alpha \equiv b \mod a \) is not known whenever the parameter valuation \( v \) is not fixed.
The automaton is transformed in a way to compute modulo \( a \). New states are of the form \((q, c)\) with \( q \in Q \) and \( c \in \{0, \ldots, a - 1\}\) expressing that \( x \equiv c \mod a \). Formally we construct \( A_b = (Q', I', F', L', \ell')\) where \( Q' = Q \times \{0, \ldots, a - 1\} \), \( I' = I \times \{0, \ldots, a - 1\} \), \( F' = F \times \{0, \ldots, a - 1\} \), \( L'(q, c) = L(q) \) and \((q, c), \tau, (q', c')\) \( \in E' \) iff \( (q, \tau, q') \in E \) and \( c' \equiv c + \tau \mod a \). Function \( I' \) is defined as follows. For any \((q, c) \in Q'\), let \( I'(q, c) = I(q) \). If \((q, c)\) contains \( x \equiv a < c\), suppress this state if \( c \neq b\), replace \( x \equiv a < c\) by \( x \leq c\) if \( c = b\). If \((q, c) \in I'\), add the \( x\)-atom \( x \equiv a, c\) and the \( \theta\)-atom \( x \equiv a, b\) to recall that \( x \equiv b \mod a\) and \( x \equiv c \mod a\) initially. As \( \alpha\) depends on the parameter valuation, value \( b\) such that \( x \equiv b \mod a\) is not known in advance. Therefore the final automaton is the disjoint union of the automata \( A_b\), with \( b \in \{0, \ldots, a - 1\}\).

The suppression of \( x\)-atoms \( x \equiv a, \alpha\) in each \( l_x(q)\) is performed similarly. In the next step, we are going to suppress \( x\)-atoms \( x \geq \alpha\). This will be possible everywhere except inside states \( q \in I\).

**Second step.** \( x\)-atoms \( x \geq \alpha\).

Let us consider a fixed \( x\)-atom \( x \geq \alpha\). Recall that the automaton is reset-free. Along a run \( \rho \in R(A^n, x_0)\), as soon as \( x \geq \alpha\) is satisfied at some configuration of \( \rho\), the next occurrences of \( x \geq \alpha\) are automatically satisfied and can be thus suppressed. The automaton is transformed in a way to count occurrences of \( x \geq \alpha\) thanks to a counter \( c\) equal to 0 (1 or 2 resp.) in case of 0 (1 or 2 and more resp.) occurrence(s) of \( x \equiv c \mod a\) is (are) encountered\(^{13}\).

Formally we construct \( A' = (Q', I', F', L', \ell')\) where \( Q' = Q \times \{0, 1, 2\}\), \( F' = F \times \{0, 1, 2\}\), \( L'(q, c) = L(q) \) and \( \ell'(q, c) = I(q)\) for all \( q \in Q\) and \( c \in \{0, 1, 2\}\). Sets \( I'\) and \( E'\) are defined as follows. For any \( q \in I\), state \((q, c)\) belongs to \( I'\) with \( c = 1\) if \( x \geq \alpha\) belongs to \( q\), and \( c = 0\) otherwise. For any \((q, \tau, q') \in E\), edge \(((q, c), \tau, (q', c'))\) belongs to \( E'\) with \( c' = c + 1\) if \( q'\) contains \( x \geq \alpha\), and \( c' = c\) otherwise. Finally, we suppress \( x \geq \alpha\) in any state \((q, 2)\) containing it.

Now, consider a run \( \rho' \in R(A^n, x_0)\) equal to \((q_i, c_i, x_i)_{0 \leq i \leq n}\) such that some state \((q_k, c_k)\) contains \( x \geq \alpha\). Necessarily, \( c_k = 1\) and \( c_i = 0\) for \( 0 \leq i < k\) by construction of \( A'\). So \( x\)-atom \( x \geq \alpha\) is satisfied at configuration \((q_k, c_k, x_k)\) iff

- \((i)\) either \( x \geq \alpha\) is satisfied at configuration \((q_0, c_0, x_0)\),
- \((ii)\) or \( x = \alpha\) is satisfied at some configuration \((q_i, c_i, x_i)\) of \( \rho'\) such that \( 0 < i \leq k\).

Therefore, \( x\)-atom \( x \geq \alpha\) can be suppressed at the cost of a new \( x\)-atom \( x = \alpha\) (see \((ii)\)), except inside the initial state \((q_0, c_0)\) (see \((i)\)). This can be achieved by modifying \( A'\) into an automaton \( A''\) thanks to a construction which is not difficult but tedious, this will be not fully detailed. The automaton \( A''\) has three parts:

- a first part of \( A''\) has to deal with paths of \( A'\) that only contain states \((q, c)\) with \( c = 0\),
- a second part has to deal with paths of \( A'\) starting with \((q, c)\) such that \( q \in I\), \( c = 1\),
- and a third part has to deal with paths of \( A'\) containing some state \((q, c)\) such that \( q \notin I\), \( c = 1\); such paths are call special.

The first part of \( A''\) is obtained from \( A'\) by erasing all states \((q, c)\) with \( c = 0\). The second part is obtained from \( A'\) by erasing all states \((q, c)\) such that \( q \notin I\), \( c = 1\) and all states \((q, c)\) such that \( q \in I\), \( c = 0\). We now discuss the third part of \( A''\). The special paths of \( A'\) must be modified into two kinds of paths: either the \( x\)-atom \( x \geq \alpha\) is added to the initial state of the path (see \((i)\)), or the \( x\)-atom \( x = \alpha\) is added to some intermediate state of the path, which is situated between the initial state (not included) and state \((q, c)\) (included).

\(^{13}\)Thus when the counter \( c\) has value 2, any incrementation \( c + 1\) lets it at value 2.
(see (ii)). In both cases, the $x$-atom $x \geq \alpha$ must be deleted from $(q, c)$. The third part of $A''$, first case, is obtained from $A'$ by adding the $x$-atom $x \geq \alpha$ to any state $(q, c)$ such that $q \in I$, $c = 0$ and by deleting the $x$-atom $x \geq \alpha$ from any state $(q, c)$ such that $q \notin I$, $c = 1$; it is also necessary to use a marker to verify that each accepting path of $A''$ corresponds to a special path of $A'$. The third part of $A''$, second case, is obtained from $A'$ as follows: the $x$-atom $x \geq \alpha$ is deleted from any state $(q, c)$ such that $q \notin I$, $c = 1$, all states $(q, c)$ with $q \notin I$, $c = 0$ are duplicated (together with the edges entering and leaving $(q, c)$) such that the $x$-atom $x = \alpha$ is added to one of the two copies of $(q, c)$; it is also necessary to use a marker to verify that each accepting path of $A''$ corresponds to a special path of $A'$ and passes through exactly one state containing the $x$-atom $x = \alpha$.

The suppression of $x$-atoms $x \leq \alpha$ can be performed in a similar way. Note that here, as soon as the last (instead of the first) occurrence of $x \leq \alpha$ is satisfied along a run $\rho \in R(A'', x_0)$, then the previous occurrences of $x \leq \alpha$ are automatically satisfied. It follows that $x$-atoms $x \leq \alpha$ can be suppressed everywhere except inside states $q \in F$.

At this point of the proof, for each state $q$, (1) if $q \notin I \cup F$, then the $x$-atoms contained in $q$ are of the form $x = \alpha$, (2) if $q \in I$, then they are of the form $x = \alpha$ or $x \geq \alpha$, and (3) if $q \in F$, then they are of the form $x = \alpha$ or $x \leq \alpha$. It remains to prove two facts about $x$-atoms which are equalities. First for all $q \in Q$, among the $x$-atoms contained in $q$, at most one is an equality $x = \alpha$. Second, for any run $\rho \in R(A'', x_0)$, for any $x$-atom $x = \alpha$, there exists at most one configuration $(q', x')$ of $\rho$ such that $I_x(q')$ contains $x = \alpha$.

### Third step. $x$-atoms $x = \alpha$.

The first fact can be easily proved. Suppose that $I_x(q) = \bigwedge_{\alpha \in A} (x = \alpha)$ for some set $A$ of linear terms. Let $\alpha' \in A$. Then $I_x(q)$ is equivalent to

$$(x = \alpha') \land \bigwedge_{\alpha \in A} (\alpha' = \alpha).$$

Thus $I_x(q)$ can be replaced by $x = \alpha'$ and $l_y(q)$ by $l_y(q) \land \bigwedge_{\alpha \in A} (\alpha' = \alpha)$.

Let us prove the second fact. Let $\rho$ be a run in $R(A'', x_0)$. Assume that there are in $\rho$ several configurations $(q_j, x_j)$, $1 \leq j \leq k$ such that $q_j$ contains a given $x$-atom $x = \alpha$. It follows that time does not progress from $(q_1, x_1)$ to $(q_k, x_k)$, that is, $x_j = x_1$ for all $j$. Only the first occurrence of $x = \alpha$ at state $q_1$ is useful, the next ones can be forgotten. Therefore, $A$ is transformed in a way to count occurrences of $x = \alpha$ and to remember any progress of time. As done before, a counter $c$ has value 0 (1 or 2 resp.) in case of 0 (1 or 2 and more resp.) occurrences of $x = \alpha$. Moreover, values 1 and 2 are indexed by $+$ if time has progressed since the first occurrence of $x = \alpha$. Formally we construct $A' = (Q', I', F', E', L', l')$ where $Q' = Q \times \{0, 1, 1_{++}, 2, 2_{++}\}$, $F' = F \times \{0, 1, 1_{++}, 2, 2_{++}\}$, $L'(q, c) = L(q)$ and $l'(q, c) = l(q)$ for all $q \in Q$ and $c \in \{0, 1, 1_{++}, 2, 2_{++}\}$. For any $q \in I$, state $(q, c)$ belongs to $I'$ with $c = 1$ if $x = \alpha$ belongs to $q$, and $c = 0$ otherwise. For any $(q, \tau, q') \in E$, edge $((q, c), \tau, (q', c'))$ belongs to $E'$ where $c'$ is computed according Table 1. Finally, for any state $(q, c)$ containing $x = \alpha$,

| \tau \backslash c | 0 | 1 | 1_{++} | 2 | 2_{++} |
|-------------------|---|----|--------|---|-------|
| 0                 | 1 | 2  | 2_{++} | 2 | 2_{++} |
| 1                 | 1 | 2  | 2_{++} | 2 | 2_{++} |

Table 1: Computation of $c'$
we suppress this state if \( c = 2_+ \), we suppress \( x = \alpha \) from this state if \( c = 2 \). Indeed recall that counter 2 indicates that it is at least the second occurrence of \( x = \alpha \), and the presence of index + means a progress of time since the first occurrence of \( x = \alpha \).

4.3. Durations in Reset-free Automata. In this subsection, we again make Hypothesis (*) . By Proposition 4.3, we know that the reset-free normalized automaton \( A \) can be supposed simplified. Thanks to this property of \( A \), we are going to construct a Presburger formula describing all the possible durations of runs in \( R(A^v, x_0) \) in terms of the parameters. We need the next notation.

**Notation 4.5.** Let \( t \) be a variable used to denote a duration and \( x \) be a variable for a clock value. We call \( t \)-atom any \( t \sim \alpha \) or \( t \sim \alpha - x \), with \( \alpha \) a linear term. A \( t \)-atom is of first type if it is of the form \( t = \alpha, t \equiv \alpha \geq \alpha, t = \alpha - x, t \equiv \alpha \geq \alpha - x \). It is of second type if it is of the form \( t \leq \alpha - x \).

A \( t \)-conjunction is a conjunction of \( t \)-atoms of second type.

**Proposition 4.6.** Let \( A \) be a reset-free normalized automaton. There exists a Presburger formula \( \lambda(t, x, \Theta) \) such that for any valuation \( v \) and any clock value \( x_0 \), there exists a run in \( R(A^v, x_0) \) with duration \( t_0 \) iff 

\[
\lambda(t_0, x_0, v(\Theta)) \text{ is TRUE.}
\]

This formula is a disjunction of formulae of the form 

\[
\lambda_t \land \lambda_\leq \land \lambda_x \land \lambda_{\theta},
\]

where \( \lambda_t \) is a first type \( t \)-atom, \( \lambda_\leq \) is a \( t \)-conjunction, \( \lambda_x \) is an \( x \)-conjunction and \( \lambda_{\theta} \) is a \( \theta \)-conjunction. Its construction is effective.

Let us explain this proposition on the next example.

**Example** Consider the simplified automaton \( A \) of Figure 4. We denote by \( t_0 \) the duration of any run \( (i, x_0) \leadsto (f, \cdot) \) in \( R(A^v, x_0) \), where \( v \) is a fixed parameter valuation. Every run has to pass through state \( q \) which contains the \( x \)-atom \( x = \theta_1 \). Let us study the possible durations \( t_1 \) of runs \( \rho_1 = (i, x_0) \leadsto (q, \cdot) \). Each duration \( t_1 \) must be equal to \( v(\theta_1) - x_0 \). For runs \( \rho_1 \) using the cycle, constraint \( v(\theta_1) > v(\theta_2) \) holds and \( t_1 \) has the form \( m + 3, m \geq 0 \). The unique run \( \rho_1 \) not using the cycle is not constrained and its duration equals \( t_1 = 2 \). Now any duration \( t_0 \) can be decomposed as \( t_0 = t_1 + 2n + 1 = v(\theta_1) - x_0 + 2n + 1, n \geq 0 \). Due to the \( x \)-atom \( x \leq \theta_2 \) of state \( f \), we get another constraint \( x_0 + t_0 \leq v(\theta_2) \). In summary, we have

\[
[(v(\theta_1) - x_0 \equiv_{1, \geq} 2) \land (v(\theta_1) > v(\theta_2)) \land (v(\theta_1) - x_0 = 2)]
\]

\[
[t_0 \equiv_{2, \geq} v(\theta_1) - x_0 + 1]
\]

\[
[x_0 + t_0 \leq v(\theta_2)]
\]
We get the next Presburger formula \( \lambda(t,x,\Theta) \)
\[
[(x \equiv_{1,\leq} \theta_1 - 3 \land \theta_1 > \theta_2) \lor x = \theta_1 - 2] \\
\land [t \equiv_{2,\geq} \theta_1 + 1 - x] \\
\land [t \leq \theta_2 - x]
\]
such that there exists a run in \( R(A^v,x_0) \) with duration \( t_0 \) iff \( \lambda(t_0,x_0,v(\Theta)) \) is true. This formula is in the form of Proposition 4.6 when it is rewritten as a disjunction of conjunctions of \( t \)-atoms, \( x \)-atoms and \( \theta \)-atoms\(^{14}\).

Thanks to the previous example, we can give some ideas of the proof of Proposition 4.6. Except for the initial and final states, the states of a simplified automaton contain at most one \( x \)-atom which is of the form \( x = \alpha \). The proof will be by induction on these \( x \)-atoms. Given an \( x \)-atom \( x = \alpha \) contained in some state \( q \), any run \( \rho \) in \( R(A^v,x_0) \) passing through this state \( q \) can be decomposed as \((i,x_0) \sim (q,x_1)\) and \((q,x_1) \sim (f,x_2)\), for some \( i \in I \) and \( f \in F \). Its duration \( t_0 \) can also be decomposed as \( t_1 + t_2 \) with the constraint that the clock value \( x_0 + t_1 \) must satisfy \( x = \alpha \). It follows that \( t_0 = v(\alpha) - x_0 + t_2 \). The durations \( t_1 \) and \( t_2 \) and the related constraints will be computed by induction. When there is no \( x \)-atom in the automaton (base case), only \( \theta \)-atoms can appear in states. Runs will therefore be partitioned according to the set of \( \theta \)-atoms that constrain them. Their durations will be described as fixed values or arithmetic progressions.

**Proof.** (of Proposition 4.6). By Proposition 4.4, the reset-free normalized \( A = (Q,I,F,E,L,l) \) is assumed to be simplified.

1. We can suppose that \( I \) is reduced to one initial state \( i \) and \( F \) to one final state \( f \). At the end of the proof, it will remain to take a disjunction over \( i \in I \) and \( f \in F \) of the constructed formulae. From now on, we suppose that \( I = \{i\} \) and \( F = \{f\} \).
2. **Assumption.** We make the assumption that \( i \) contains no \( x \)-atom and \( f \) contains no \( x \)-atom \( x \leq \alpha \). As \( A \) is simplified, this means that for any state \( q \in Q \), either \( l_x(q) = \top \) or \( l_x(q) \) equals some \( x = \alpha \). The proof is done by induction on the \( x \)-atoms \( x = \alpha \) that appear as \( l_x(q) \) with \( q \in Q \). The formula \( \lambda(t,x,\Theta) \) that we will construct will have no \( t \)-conjunction, that is \( \lambda(t,x,\Theta) \) will be a disjunction of formulae of the form \( \lambda_I \land \lambda_x \land \lambda_\theta \).

**Base case.** Suppose that \( l_x(q) = \top \) for all \( q \in Q \), that is \( l(q) = l_\theta(q) \). Durations of runs in \( R(A^v,x_0) \) are thus independent on the clock values. They are simply equal to the number of edges labeled by \( \tau = 1 \) along runs from \( i \) to \( f \). And each of these runs is associated a constraint which is the conjunction of the \( \theta \)-atoms contained in the states of the run.

The proof is based on the classical Kleene theorem\(^{10}\) using the particular alphabet
\[
B = \{(\tau,\varsigma) \mid \tau \in \{0,1\}, \varsigma \in \{l_\theta(q), q \in Q\}\}.
\]
To any edge \((q,\varsigma,q')\) of \( A \) corresponds the letter \((\tau,l_\theta(q'))\) of \( B \). The concatenation \( \cdot \) of two letters \((\tau_1,\varsigma_1)\) and \((\tau_2,\varsigma_2)\) is defined as \((\tau_1 + \tau_2, \varsigma_1 \land \varsigma_2)\). Thus a word over \( B \) is equal to \((t,\varsigma)\) where \( t \) is a positive integer (a duration) and \( \varsigma \) is a \( \theta \)-conjunction (a constraint on the parameters). In particular, the empty word is equal to \((0,\top)\). The star operation \(*\) is defined as usual and the plus operation \( + \) is defined by \( L^+ = L^* \setminus \{(0,\top)\} \).

We denote by \( \text{Rat}_B(\cdot,\cdot) \) the smallest family of languages containing \( B \) and closed

\(^{14}\lambda_I \) is equal to \( t \equiv_{2,\geq} \theta_1 + 1 - x \) and \( \lambda_\leq \) is equal to \( t \leq \theta_2 - x \).

\(^{15}\)This notation should not be confused with the one used for the union operation.
under $\cdot$ and $\dot{+}$. The elements of a set $L \in \text{Rat}_B(\cdot, \dot{+})$ have a simple form. The second components of these elements are all identical because operation $\wedge$ is idempotent. The first components constitute a set which is the union of a finite set and a finite number of arithmetic progressions $[2]$. In other words $L$ is described by a disjunction of formulae of the form $\lambda_t \wedge \lambda_\theta$ such that $\lambda_\theta$ equals a fixed $\theta$-conjunction $\varsigma$ and $\lambda_t$ equals either $t = \alpha$ or $t \equiv_{a, \geq} \alpha$ with $\alpha \in \mathbb{N}$.

Now by Kleene’s theorem applied to $A$, we get a rational language over $B$ whose first components describe the durations of all runs of $\mathcal{R}(A^v, x_0)$ and the second components describe the related constraints. It is not difficult to prove that this rational language can be rewritten as a finite union of languages in $\text{Rat}_B(\cdot, \dot{+})$. We thus get the required formula $\lambda(t, x, \Theta)$ as a disjunction of formulae $\lambda_t \wedge \lambda_\theta$ where $\lambda_t$ is a first-type $t$-atom and $\lambda_\theta$ is a $\theta$-conjunction.

**General case.** Now consider a particular $x$-atom $x = \alpha$. Let us denote by $P$ the set of states $p$ such that $l_x(p)$ is equal to $x = \alpha$. As $A$ is simplified, any run $\rho$ of $\mathcal{R}(A^v, x_0)$ contains 0 or 1 state of $P$ (see the second part of Definition 4.3). We are going to prove that the expected formula $\lambda(t, x, \Theta)$ is equal to

$$\lambda^{Q/P}(t, x, \Theta) \lor \bigvee_{p \in P} \lambda^p(t, x, \Theta)$$

where $\lambda^{Q/P}$ describes durations of runs containing no state of $P$, and $\lambda^p$ describes durations of runs containing one occurrence of the state $p$ of $P$.

All runs containing no state of $P$ constitute the set $\mathcal{R}(A^v, x_0)$ of an automaton $A'$ obtained from $A$ by erasing states in $P$. As $A'$ has one $x$-atom less, $\lambda^{Q/P}(t, x, \Theta)$ can be constructed by induction hypothesis.

Let us now fix $p \in P$ and a run $\rho \in \mathcal{R}(A^v, x_0)$ that contains it. This run is decomposed into a run $\rho_1 = (i, x_0) \sim (p, x_1)$ with duration $t_1$, and a run $\rho_2 = (p, x_1) \sim (f, x_2)$ with duration $t_2$. Duration $t_0$ of $\rho$ is equal to $t_1 + t_2$ such that $x_1 = x_0 + t_1$, $x_2 = x_1 + t_2$ and $x_1$ satisfies $x = \alpha$. Durations $t_1$ and $t_2$ can be computed by induction in the following way.

Let us begin with $t_1$. The automaton $A$ is modified into $A^{p,1}$ by erasing states of $P \setminus \{p\}$ and edges leaving $p$. Invariant $l_x(p)$ is replaced by $\top$. The new unique final state is $p$. The new automaton has one $x$-atom less, so $\lambda^{p,1}(t, x, \Theta)$ can be constructed by induction hypothesis such that $\lambda^{p,1}(t_1, x_0, v(\Theta))$ is TRUE. Formula $\lambda^{p,1}$ is a disjunction of formulae $\lambda^1_t \wedge \lambda^1_x \wedge \lambda^1_\theta$ where $\lambda^1_t$ is a first type $t$-atom, $\lambda^1_x$ is an $x$-conjunction and $\lambda^1_\theta$ is a $\theta$-conjunction. Suppose that $\lambda^1_t$ is one among

\[ t = \alpha_1, \quad t \equiv_{a, \geq} \alpha_1, \quad t = \alpha_1 - x, \quad t \equiv_{a, \geq} \alpha_1 - x. \]  

As $x_1$ satisfies $x = \alpha$ and $x_1 = x_0 + t_1$, then

\[ x_1 = v(\alpha), \quad t_1 = v(\alpha) - x_0. \]  

So in (4.1), $t$ can be replaced by $\alpha - x$ and (4.1) becomes

\[ \alpha - x = \alpha_1, \quad \alpha - x \equiv_{a, \geq} \alpha_1, \quad \alpha = \alpha_1, \quad \alpha \equiv_{a, \geq} \alpha_1. \]

Thus $\lambda^1_t$ becomes an $x$-atom or a $\theta$-atom. The modified formula $\lambda^1_t \wedge \lambda^1_x \wedge \lambda^1_\theta$ is denoted by

\[ \lambda^1_x \wedge \lambda^1_\theta. \]
Let us now describe $t_2$. We modify $A$ into $A^p,2$ by erasing states of $P \setminus \{p\}$ and edges entering $p$. Formula $l_x(p)$ is replaced by $\top$. The new unique initial state is $p$. By induction hypothesis, $\lambda^{p,2}(t, x, \Theta)$ is constructed as a disjunction of formulae $\lambda^2_x \wedge \lambda^2_x \wedge \lambda^2_\theta$ where $\lambda^2_\theta$ is one among

$$
t = \alpha_2, \quad t \equiv_{a, \geq} \alpha_2, \quad t = \alpha_2 - x, \quad t \equiv_{a, \geq} \alpha_2 - x.
$$

(4.4)

Recall that $\lambda^{p,2}(t, x, \Theta)$ describes the duration $t_2$ of runs $\rho_2 = (p, x_1) \leadsto (f, x_2)$ for which $x_1$ satisfies $x = \alpha$. Thus in (4.4), $x$ can be replaced by $\alpha$ and (4.4) becomes

$$
t = \alpha_2, \quad t \equiv_{a, \geq} \alpha_2, \quad t = \alpha_2 - \alpha, \quad t \equiv_{a, \geq} \alpha_2 - \alpha.
$$

This shows that $\lambda^2_\theta$ is now of the form

$$
t = \beta \quad \text{or} \quad t \equiv_{a, \geq} \beta.
$$

(5.5)

Moreover $\lambda^2_x$ becomes a $\theta$-conjunction when $x$ is replaced by $\alpha$. The modified formula $\lambda^2_x \wedge \lambda^2_\theta$ is denoted by

$$
\lambda^2_\beta.
$$

(6.6)

Finally, we can describe $t_0 = t_1 + t_2$. By (4.2) and (4.5), it has the form

$$
t_0 = v(\alpha) - x_0 + v(\beta) \quad \text{or} \quad t_0 \equiv_{a, \geq} v(\alpha) - x_0 + v(\beta).
$$

(7.7)

Hence formula $\lambda^p(t, x, \Theta)$ for $t_0$ is a disjunction of formulae $\lambda_t \wedge \lambda_x \wedge \lambda_\theta$ such that $\lambda_t$ has the form (see (4.7)) $t = \alpha - x + \beta$ or $t \equiv_{a, \geq} \alpha - x + \beta$ and $\lambda_x \wedge \lambda_\theta$ has the form (see (4.3) and (4.6)) $\lambda^1_x \wedge \lambda^1_\theta \wedge \lambda^2_\theta$.

(3) Under the assumption that $i$ contains no $x$-atoms and $f$ contains no $x$-atom $x \leq \alpha$, we have constructed a formula $\lambda(t, x, \Theta)$ with no $t$-conjunction. So we have to take into account the $x$-conjunction $l_x(i)$ and the $x$-atoms $x \leq \alpha$ appearing in $f$. Thus $x_0$ must satisfy $l_x(i)$ and $x_0 + t_0$ must satisfy all $x \leq \alpha$ in $f$. It follows that the final formula is equal to

$$
\lambda(t, x, \Theta) \wedge l_x(i)(x, \Theta) \wedge \bigwedge_{x \leq \alpha \in f} t \leq \alpha - x.
$$

(8.8)

Remark 4.7. Suppose that $A$ is an automaton such that $l(i)$ equals $x = 0$ for each initial state $i \in I$. Then formula $\lambda(t, x, \Theta)$ of Proposition (4.6) contains the $x$-atom $x = 0$ (see (4.8)). Hence, if $\lambda(t_0, x_0, v(\Theta))$ is true, then necessarily $x_0 = 0$, which can been interpreted as a reset of the clock. This remark will be used in the next subsection.

4.4. Durations in General. This subsection is devoted to the proofs of Propositions 3.9 and 3.10. Here there is no longer the restriction on the automaton given by Hypothesis (*): it is any automaton as in Definition 2.2. This automaton is supposed to be normalized by Proposition 2.2. Thus, given a state $q$, the edges $(p, r, g, r, q)$ entering $q$ all have the same $r$. We call $q$ a reset-state in case $r = \{x\}$. The set of reset-states of $A$ is denoted by $Q_R$.

Let $A = (Q, E, L, l)$ be an automaton. Let us fix two states $q, q'$, a parameter valuation $v$, a clock value $x_0$. We denote by

$$
R_{q,q'}(A^v, x_0)
$$

the set of runs $\rho = (q, x_0) \leadsto (q', \cdot)$ in $A^v$. Let us study this set.
A run \( \rho \) in \( R_{q,q'}(A^v, x_0) \) possibly contains some reset-states. It thus decomposes as a sequence of \( k \geq 1 \) runs \( \rho_j \), \( 1 \leq j \leq k \), such that for any \( j \), \( \rho_j \) contains no reset-state, except possibly for the first and the last configurations of \( \rho_j \). The duration \( D_{\rho_j} \) of each \( \rho_j \) can be computed thanks to Proposition 4.6. For any \( j \), \( 1 \leq j \leq k \), let us denote by \( \lambda_j(t,x,\Theta) \) the Presburger formula corresponding to \( D_{\rho_j} \) which is a disjunction of formulae \( \lambda_t \land \lambda_\le \land \lambda_x \land \lambda_\Theta \). So the total duration \( D_{\rho} \) of runs \( \rho \) in \( R_{q,q'}(A^v, x_0) \) is equal to the sum \( \Sigma_{1 \leq j \leq k} D_{\rho_j} \). We will see that the durations \( D_{\rho} \) of runs \( \rho \) in \( R_{q,q'}(A^v, x_0) \) can be symbolically represented thanks to rational expressions on an alphabet whose letters are the formulae \( \lambda_t \land \lambda_\le \land \lambda_x \land \lambda_\Theta \) that appear in the \( \lambda_j(t,x,\Theta) \)'s. Thanks to this symbolic description and because our logic is the fragment F-PTCTL, we will be able to prove Propositions 3.9 and 3.10. It should be noted that the durations \( D_{\rho} \) of runs \( \rho \) in \( R_{q,q'}(A^v, x_0) \) cannot be described by a Presburger formula as in Proposition 4.6; otherwise the model-checking problem for PTCTL would be decidable (see Corollary 3.3).

Let us now explain in details all these ideas.

In a first step, we construct from \( A \) several reset-free normalized automata as in Hypothesis (*). The construction is a standard one in automata theory. Runs \( \rho_j \) mentioned before will be runs in these automata and their durations will be described thanks to Proposition 4.6.

First construction. For each couple \((p, p')\) of states of \( A \) such that \( p \in \{ q \} \cup Q_R \) and \( p' \in \{ q' \} \cup Q_R \), we construct from \( A \) the following reset-free automaton \( A_{p,p'} = (Q', I', E', F') \). The set \( Q' \) of states is \((Q \setminus Q_R) \cup \{ \overline{p}, \overline{p}' \} \) where \( \overline{p}, \overline{p}' \) are copies of \( p, p' \). The unique initial state is \( \overline{p} \) and the unique final state is \( \overline{p}' \). Let \( L'(\overline{p}) = L(p) \) and \( L'(\overline{p}') = L(p') \). Let \( l'(\overline{p}) \) be equal to \( l(p) \) if \( p = q \) and to \( (l(p) \land x = 0) \) if \( p \neq q \). Let \( l'(\overline{p}') \) be equal to \( l(p') \) if \( p' \notin Q_R \) and to \( (l(p') \land x = 0) \) if \( p' \in Q_R \). The set \( E' \) of edges is the union of \( E \) restricted to \( Q \setminus Q_R \) with the next set of new edges\(^{11}\):

\[
\begin{align*}
(p_1, \tau, g, r, p_1) & \quad \text{if } (p, \tau, g, r, p_1) \in E \\
(p_1, \tau, g, r, p_1') & \quad \text{if } (p_1, \tau, g, r, p_1') \in E \\
(\overline{p}, \tau, g, \emptyset, \overline{p}') & \quad \text{if } (\overline{p}, \tau, g, \emptyset, \overline{p}') \in E.
\end{align*}
\]

In this way, automaton \( A_{p,p'} \) satisfies Hypothesis (*).

Let \( p \in \{ q \} \cup Q_R \) and \( p' \in \{ q' \} \cup Q_R \). We define \( x_1 \) to be equal to \( x_0 \) if \( p = q \), and to 0 if \( p \neq q \). The runs of \( R(A_{p,p'}, x_1) \) are exactly the non-empty runs \((p, x_1) \rightsquigarrow (p', \cdot)\) of \( A^v \) that pass through no reset-state (except possibly the first and the last states of the run). The durations of runs in \( R(A_{p,p'}, x_1) \) are described by formula \( \lambda^{p,p'}(t, x, \Theta) \) of Proposition 4.6. This formula is a disjunction \( \bigvee_j \lambda^{p,p'j} \) of formulae

\[
\lambda^{p,p'j} = \lambda^{p,p'j}_t \land \lambda^{p,p'j}_\le \land \lambda^{p,p'j}_x \land \lambda^{p,p'j}_\Theta.
\] (4.9)

For each couple \((p, p')\) and each \( j \), we associate a distinct letter \( b_{p,p'j} \) to each formula \( \lambda^{p,p'j} \). The set of all these letters is denoted by \( B \). We say that letter \( b_{p,p'j} \) is a reset-letter if \( p \) is a reset-state. The set of reset-letters is denoted \( B_R \).

In a second step, we construct another automaton from \( A \) in a way so to show how a run of \( R_{q,q'}(A^v, x_0) \) is decomposed into a sequence of runs \( \rho_j \) according to reset-states of \( A \). This automaton will be a classical automaton\(^\dagger\).

\(^{11}\)The \( x \)-atom \( x = 0 \) imposes a reset of the clock at state \( p \) (see Remark 4.7).

\(^\dagger\)As \( A_{p,p'} \) must satisfy Hypothesis (*), no reset can appears on the edges.
Second construction. We construct an automaton $B$ over the alphabet $B$ as follows. The set of states equals $Q_R \cup \{q,q'\}$ and the set of edges equals $\{(p,b,p') \mid b = b_{p,p'}j \text{ for some } j\}$. The unique initial (resp. final) state is $q$ (resp. $q'$).

So, any run $\rho$ of $R_{q,q'}(A^v, x_0)$ is map into a path in $B$ from $q$ to $q'$ which indicates how $\rho$ is decomposed according to reset-states of $A$. The duration of $\rho$ is symbolically represented by the word that labels the corresponding path in $B$. Hence the set of durations of runs of $R_{q,q'}(A^v, x_0)$ is symbolically represented by the rational subset accepted by $B$. We denote by

$$L_{q,q'}$$

this subset of $B^*$. Any word of $L_{q,q'}$ has at most one letter that is non reset (the first letter of the word).

We now study in details rational expressions over the alphabet $B$ and in particular the rational expression defining $L_{q,q'}$.

Rational expressions. Let $L^+$ be denoting $L^* \setminus \{\epsilon\}$ with $\epsilon$ denoting the empty word and $\text{Rat}_B(\cdot,^+)$ be the smallest family closed under $\cdot$ and $+$, and containing $B$. One can prove that any rational language over $B$ can be effectively rewritten as a finite union of languages in $\{\epsilon\} \cup \text{Rat}_B(\cdot,^+)$. Therefore

$$L_{q,q'} = \bigcup_i L_i$$

(4.10)

with

$$L_i = \{\epsilon\} \text{ or } L_i = \{b_i\} \text{ or } L_i = b_i \cdot K_i$$

such that $b_i \in B, K_i \in \text{Rat}_B(\cdot,^+)$. The set $R_{q,q'}(A^v, x_0)$ is decomposed into

$$R_{q,q'}(A^v, x_0) = \bigcup_i R_i$$

(4.11)

according to (4.10).

An non empty word of $L_{q,q'}$ is a sequence $b_1 b_2 \cdots b_n \in B^+$. The first letter $b_1$ describes runs from state $q$ to some reset-state $p_1$, the clock value at $q$ is $x_0$. Each letter $b_i$, $i \geq 2$, is a reset-letter. If $2 \leq i < n$, $b_i$ describes runs from reset-state $p_{i-1}$ to reset-state $p_i$, the clock value at $p_{i-1}$ is 0. If $i = n$, $b_i$ describes runs from reset-state $p_{n-1}$ to state $q'$, the clock value at $p_{n-1}$ is 0. Let

$$\lambda_i^1 \wedge \lambda_i^2 \wedge \lambda_x^i \wedge \lambda_y^i$$

(4.12)

be the formula associated to each letter $b_i$, $i \geq 1$ (see [12]). Whenever $i \geq 2$, $\lambda_x^i$ contains the $x$-atom $x = 0$ by Remark 4.7 and Definition of automaton $A_{p,p'}$. In this case, we prefer to work with the equivalent formula

$$\kappa_i^1 \wedge \kappa_i^2 \wedge \kappa_y^i$$

(4.13)

such that $x$ has been replaced by 0 in (4.12) (in particular, $\lambda_x$ becomes a $\theta$-conjunction).

In this formula $\kappa_i^1$ is a $t$-atom of the form $t = \alpha$ or $\equiv_{a_\geq \alpha}$, $\kappa_i^2$ is a conjunction of $t$-atoms of the form $t \leq \alpha$ and $\kappa_y^i$ is a $\theta$-conjunction.

---

18The sequence $b_1 b_2 \cdots b_n$ symbolically represents certain runs of $R_{q,q'}(A^v, x_0)$. We are only interested in the initial clock value $x_0$ treated by formula $\lambda_x^1$ of $b_1$. 

The unique initial (resp. final) state is $q$ (resp. $q'$).
The concatenation $b_1 \cdot b_2 \cdots \cdot b_n$ is interpreted as follows. It is the sum $t_1 + t_2 + \cdots + t_n$ of the durations $t_1, t_2, \ldots, t_n$ respectively described by $\lambda^1, \kappa^2, \ldots, \kappa^n$. It is the conjunction of the related constraints
\[
(\lambda^1 \land \kappa^2 \land \cdots \land \kappa^n) \land \lambda_x \land (\lambda^1 \land \kappa^2 \land \cdots \land \kappa^n).
\]
Formulae $\lambda^1, \kappa^2, \ldots, \kappa^n$ impose upper bounds on $t_1, t_2, \ldots, t_n$. The $x$-conjunction imposes constraints on the clock value $x_0$. The $\theta$-conjunction $(\lambda^1 \land \kappa^2 \land \cdots \land \kappa^n)$ impose constraints on the parameters.

In the next lemmas, we show that certain properties of runs in $R_i$ can be expressed in Presburger arithmetics thanks to the symbolic representation $L_i$ of $R_i$ (see (4.10) and (4.11)). After these lemmas, we will be fully equipped to prove Propositions 3.9 and 3.10. Note that Proposition 3.10 can only be proved with $\sim$ limited to $\{<, \leq, >, \geq\}$, otherwise the model-checking problem for PTCTL would be decidable.

**Lemma 4.8.** One can construct a $B_{x, \theta}$ formula $\text{NonEmpty}_{L_i}(x, \theta)$ such that for any valuation $v$ and any clock value $x_0$, $\text{NonEmpty}_{L_i}(x_0, v(\theta))$ is TRUE iff $R_i$ is non empty.

**Proof.** Runs of $R_i$ have durations that are symbolically represented by the words of $L_i$. Let us construct formula $\text{NonEmpty}_{L_i}$ by induction on the rational expression defining $L_i$ (see (4.10)). This formula will be equal to $\eta_x \land \eta_{\theta}$ with $\eta_x$ an $x$-conjunction imposing constraints on the clock and $\eta_{\theta}$ a $\theta$-conjunction imposing constraints on the parameters.

Suppose $L_i = \{\epsilon\}$, then $\text{NonEmpty}_{L_i}(x, \theta)$ equals $x = 0$ if $q$ is a reset-state and $l(q)(x, \Theta)$ otherwise. Indeed, under these constraints, $R_i$ is non empty since it contains the empty run with the null duration. Suppose that $L_i = \{b_i\}$ with $b_i \in B$ and associated formula $\lambda^1 \land \lambda^2 \land \lambda_x \land \lambda_{\theta}$. Recall that $\lambda^1$ is one among the $t$-atoms $t = \alpha, t = \alpha - x, t \equiv_{a, \geq} \alpha$ or $t \equiv_{a, \geq} \alpha - x$ and that $\lambda_x^1$ is of the form $\bigwedge_{\beta} t \leq \beta - x$. It follows that the non emptiness of $R_i$ can be expressed thanks to the minimum duration $t = \alpha$ ($t = \alpha - x$ resp.) of runs in $R_i$. Then

\[
\text{NonEmpty}_{L_i}(x, \Theta) = (\bigwedge_{\beta} \alpha \leq \beta - x) \land \lambda_x \land \lambda_{\theta}
\]

(4.14)

Suppose now that $L_i = b_i \cdot K_i$ with $b_i \in B$ and $K_i \in \text{Rat}_{B_R}(\cdot, +)$. Let us first prove by induction on the rational expression defining $K_i$ that $\text{NonEmpty}_{K_i}(\Theta)$ equals some $\theta$-conjunction $\eta_{\theta}$. Let $K_i = \{b_i\}$ with $b_i \in B_R$. We obtain a formula similar to (4.14) where $x$ is replaced by 0 (see (4.13)), so

\[
\text{NonEmpty}_{K_i}(\Theta) = (\bigwedge_{\beta} \alpha \leq \beta) \land \kappa_{\theta}.
\]

Suppose that $K_i = K \cdot K'$ and formulae $\text{NonEmpty}_K$, $\text{NonEmpty}_{K'}$, have been constructed by induction. Then $\text{NonEmpty}_{K_i}(\Theta) = \text{NonEmpty}_K(\Theta) \land \text{NonEmpty}_{K'}(\Theta)$ because the non emptiness of $R_i$ requires the non emptiness of both $K$ and $K'$. If $K_i = K^+$, then $\text{NonEmpty}_{K_i}(\Theta) = \text{NonEmpty}_K(\Theta)$ because conjunction in an idempotent operation. Finally for $L_i = b_i \cdot K_i$, we get $\text{NonEmpty}_{L_i}(x, \Theta) = \text{NonEmpty}_{\{b_i\}}(x, \Theta) \land \eta_{\theta}$ where $\text{NonEmpty}_{\{b_i\}}(x, \Theta)$ is formula (4.14) and $\eta_{\theta}$ is the formula just constructed for $K_i$. \[\]
Lemma 4.9. One can construct a $B_{x,\Theta}$ formula $\text{NonNull}_{L_t}(x, \Theta)$ such that for any valuation $v$ and any clock value $x_0$, $\text{NonNull}_{L_t}(x_0, v(\Theta))$ is true iff $R_t$ contains a run with a non null duration.

Proof. The proof is in the same vein as for Lemma 4.8 with a similar form $\eta_x \land \eta_\theta$ for $\text{NonNull}_{L_t}(x, \Theta)$.

If $L_i = \{c\}$, then clearly $\text{NonNull}_{L_{t_i}}(x, \Theta) = \perp$. If $L_i = \{b_i\}$ with $b_i \in B$ and associated formula $\lambda_i^t \land \lambda_i^{x} \land \lambda_i^{\theta}$. Let us study as before formulae $\lambda_i^t$ and $\lambda_i^x$, where $\lambda_i^x = \bigwedge \lambda_i(t \leq \beta - x)$. If $\lambda_i^t$ equals $\alpha$, then $t$ is non null iff $\alpha > 0$. Then $\text{NonNull}_{L_{t_i}}(x, \Theta)$ is the formula $(\alpha > 0) \land (\bigwedge \lambda_i \alpha \leq \beta - x) \land \lambda_i^x \land \lambda_i^\theta$. When $\lambda_i^t$ is $t = \alpha - x$, we have a similar formula with $t$ non null if $\alpha > 0$. If $\lambda_i^t$ equals $t \equiv_{a>0} \alpha$, then a possible formula for $t$ is either $\alpha$ if $\alpha > 0$ or $\alpha$ if $\alpha = 0$. We get formula $\text{NonNull}_{L_{t_i}}(x, \Theta)$ equal to $(\alpha > 0) \land (\bigwedge \lambda_i(a \leq \beta - x)) \land \lambda_i^x \land \lambda_i^\theta$. A similar argument holds if $\lambda_i^t$ equals $t \equiv_{a>0} \alpha - x$.

Let $L_i = b_i \cdot K_i$, with $b_i \in B$ and $K_i \in \text{Rat}_{B_R}(\cdot, \cdot)$. Let us first construct formula $\text{NonNull}_{K_i}(\Theta)$ by induction on $K_i$. This formula will be a $\theta$-conjunction. If $K_i = \{b_i\}$ with $b_i \in B_R$, we get a formula $\text{NonNull}_{K_i}$ as for the case $L_i = \{b_i\}$ such that $x$ is replaced by $0$.

If $K_i = K \cdot K'$, then there exists a non null duration in $K_i$ iff there exists some duration in $K$ and some other in $K'$ and one of them is non null. Thus $\text{NonNull}_{K_i}(\Theta)$ equals $(\text{NonNull}_{K_i}(\Theta) \land \text{NonEmpty}_{K'}(\Theta)) \lor (\text{NonEmpty}_{K}(\Theta) \land \text{NonNull}_{K'}(\Theta))$. If $K_i = K^+$, then $\text{NonNull}_{K_i}(\Theta) = \text{NonNull}_{K}(\Theta)$. Finally, for $L_i = b_i \cdot K_i$, we get the formula $(\text{NonNull}_{b_i}(x, \Theta) \land \text{NonEmpty}_{K_i}(\Theta)) \lor (\text{NonEmpty}_{b_i}(x, \Theta) \land \text{NonNull}_{K_i}(\Theta))$. }

Lemma 4.10. One can construct a $B_{x,\Theta}$ formula $\text{NonZeno}_{L_t}(x, \Theta)$ such that for any valuation $v$ and any clock value $x_0$, $\text{NonZeno}_{L_t}(x_0, v(\Theta))$ is true iff $R_t$ contains runs with arbitrarily large durations.

Proof. The proof is again similar.

Suppose $L_i = \{c\}$, then clearly $\text{NonZeno}_{L_{t_i}}(x, \Theta) = \perp$. Let $L_i = \{b_i\}$ with $b_i \in B$ and associated formula $\lambda_i^t \land \lambda_i^{x} \land \lambda_i^{\theta}$. If $\lambda_i^t$ equals $t = \alpha$ or $t = \alpha - x$, then $\text{NonZeno}_{L_{t_i}}(x, \Theta) = \perp$. If $\lambda_i^t$ equals $t \equiv_{a>0} \alpha$, then $t$ is arbitrarily large iff $\lambda_i^t = \top$. In this case, $\text{NonZeno}_{L_t}(x, \Theta) = \lambda_i^x \land \lambda_i^\theta$, otherwise $\text{NonZeno}_{L_t}(x, \Theta) = \perp$.

Suppose now that $L_i = b_i \cdot K_i$. We begin to construct a $\theta$-conjunction $\text{NonZeno}_{K_i}(\Theta)$ by induction on $K_i$. If $K_i = \{b_i\}$ with $b_i \in B_R$, then the formula is as in the case $L_i = \{b_i\}$ with $x$ replaced by $0$. If $K_i = K \cdot K'$, then $\text{NonZeno}_{K_i}(\Theta)$ equals $(\text{NonZeno}_{K}(\Theta) \land \text{NonEmpty}_{K'}(\Theta)) \lor (\text{NonEmpty}_{K}(\Theta) \land \text{NonZeno}_{K'}(\Theta))$. If $K_i = K^+$, then $K_i$ has arbitrarily large durations iff $K$ contains a non null duration, that is $\text{NonZeno}_{K_i}(\Theta) = \text{NonNull}_{K_i}(\Theta)$. Thus we get for $L_i = b_i \cdot K_i$ the formula

$$(\text{NonZeno}_{b_i}(x, \Theta) \land \text{NonEmpty}_{K_i}(\Theta)) \lor (\text{NonEmpty}_{b_i}(x, \Theta) \land \text{NonZeno}_{K_i}(\Theta)).$$

Lemma 4.11. One can construct a Presburger formula $\text{Min}_{L_t}(t, x, \theta)$ such that for any valuation $v$ and any clock value $x_0$, $\text{Min}_{L_t}(t_0, x_0, v(\Theta))$ is true iff $t_0$ is the minimum duration of runs of $R_t$. This formula is equal to $\mu_t \land \mu_x \land \mu_\theta$ such that $\mu_t$ is of the form $t = \alpha$ or $t = \alpha - x$, $\mu_x$ is an $x$-conjunction and $\mu_\theta$ is a $\theta$-conjunction.

Proof. In this proof, we have to describe the minimum duration by the variable $t$ and the constraints on it by $\mu_x$ and $\mu_\theta$. 
Let \( L_i = \{ \epsilon \} \), then \( \text{Min}_{L_i}(t, x, \Theta) \) is equal to \((t = 0) \land (x = 0)\) if \( q \) is a reset-state, and \((t = 0) \land l(q)(x, \Theta)\) otherwise. Let \( L_i = \{ b_i \} \) with \( b_i \in B \). Then looking at the form of \( \lambda_i^t \), the minimum duration equals \( \alpha \) (\( \alpha - x \) resp.) (see (4.14) and the sentence just before). Therefore formula \( \text{Min}_{L_i}(t, x, \Theta) \) is equal to

\[
(t = \alpha) \land \left( \bigwedge_{\beta} \alpha \leq \beta - x \right) \land \lambda_x^i \land \lambda_\theta^i
\]

(4.15)

\[
(\quad (t = \alpha - x) \land \left( \bigwedge_{\beta} \alpha \leq \beta \right) \land \lambda_x^i \land \lambda_\theta^i \quad \text{resp.})
\]

Suppose \( L_i = b_i \cdot K_i \). Let us begin to construct formula \( \text{Min}_{K_i}(t, \Theta) \) the form of which will be \( \mu_t \land \mu_\theta \). If \( K_i = \{ b_i \} \) with \( b_i \in B_R \), then \( \text{Min}_{K_i}(t, \Theta) \) equals \((4.15)\) with \( x \) replaced by 0. If \( K_i = K \cdot K' \), then the minimum duration in \( K_i \) equals the sum of the minimum durations in \( K \) and \( K' \). Hence, if \( \text{Min}_K(t, \Theta) = (t = \alpha) \land \mu_\theta \) and \( \text{Min}_{K'} = (t = \alpha') \land \mu_\theta' \), then \( \text{Min}_{K_i}(t, \Theta) \) is equal to \((t = \alpha + \alpha') \land \mu_\theta \land \mu_\theta' \). If \( K_i = K^+ \), then the minimum duration in \( K_i \) is the minimum duration in \( K \), i.e. \( \text{Min}_{K_i}(t, \Theta) = \text{Min}_K(t, \Theta) \). Let us come back to \( L_i = b_i \cdot K_i \). Let \( \text{Min}_i(t, x, \Theta) \) be equal to \((4.15)\) and \( \text{Min}_{K_i}(t, \Theta) \) be equal to \((t = \alpha') \land \mu_\theta \). Then \( \text{Min}_{L_i}(t, \Theta) \) is equal to \((t = \alpha + \alpha') \land (\bigwedge_{\beta} \alpha \leq \beta - x) \land \lambda_x^i \land \lambda_\theta^i \land \mu_\theta \) (resp. \((t = \alpha + \alpha' - x) \land (\bigwedge_{\beta} \alpha \leq \beta) \land \lambda_x^i \land \lambda_\theta^i \land \mu_\theta \)).

In the next lemma, we are going to construct a formula \( \text{Max}_{L_i}(t, x, \Theta) \) that describes the maximum duration \( t \) in \( L_i \). Note that durations \( t \) in \( L_i \) can be arbitrarily large (see Lemma (4.10)). We will thus denote symbolically by \( t = \infty \) the (non existing) maximum duration.

**Lemma 4.12.** One can construct a formula \( \text{Max}_{L_i}(t, x, \Theta) \) such that for any valuation \( v \) and any clock value \( x_0 \), \( \text{Max}_{L_i}(t_0, x_0, v(\theta)) \) is true iff \( t_0 \) is the maximum duration of runs of \( R_i \). This formula is equal to a disjunction of formulae \( M_t \land M_x \land M_\theta \) such that \( M_t \) is of the form \( t = \alpha \), \( t = \alpha - x \) or \( t = \infty \), \( M_x \) is an \( x \)-conjunction and \( M_\theta \) is a \( \theta \)-conjunction.

**Proof.** If \( L_i = \{ \epsilon \} \), then \( \text{Max}_{L_i} \) is \((t = 0) \land (x = 0)\) if \( q \) is a reset-state, and to \((t = 0) \land l(q)(x, \Theta)\) otherwise. Let \( L_i = \{ b_i \} \) with \( b_i \in B \). Let us study \( \lambda^t_x \) and \( \lambda^t_\theta \) equal to \( \bigwedge_{\beta} (t \leq \beta - x) \). If \( \lambda^t_x = t = \alpha \), then \( \text{Max}_{L_i}(t, x, \Theta) \) equals \( \lambda^t_x \land \bigwedge_{\beta} (\alpha \leq \beta - x) \land \lambda_x^i \land \lambda_\theta^i \). A similar formula holds when \( \lambda^t_x \) equals \( t = \alpha - x \). If \( \lambda^t_x = t \equiv_{a \geq \alpha} \alpha \) with \( \lambda_x^i = \top \), then \( \text{Max}_{L_i}(t, x, \Theta) \) equals \((t = \infty) \land \lambda_x^i \land \lambda_\theta^i \). Suppose that \( \lambda^t_x \) is \( t \equiv_{a \geq \alpha} \alpha \) with \( \lambda_x^i \) being a non empty conjunction \( \bigwedge_{\beta} (t \leq \beta - x) \). Then the maximum duration is the greatest value \( \alpha + ay \), for some \( y \in \mathbb{N} \), which is less than or equal to the smallest among the \( \beta - x \)'s, denoted by \( \beta' - x \). Assume that \( \beta' - x \equiv b \mod a \) and \( \alpha \equiv c \mod a \) for some \( b, c \in \{0, \ldots, a - 1 \} \). If \( b \geq c \), then the maximum duration is given by formula \( M_t \) equal to \( t = \beta' - x - (b - c) \) under the condition \( m_\theta \) equal to \( t \geq \alpha \), i.e. \( \beta' - x - (b - c) \geq \alpha \). If \( b < c \), then \( M_t \) equals \( t = \beta' - x - (a + b - c) \) under the condition \( m_\theta \) equal to \( \beta' - x - (a + b - c) \geq \alpha \). Thus \( \text{Max}_{L_i}(t, x, \Theta) \) is a disjunction over the different possible values of \( \beta' \), \( b \) and \( c \) of formulae

\[
M_t \land m_\theta \land \lambda_\theta \land M_{\beta', x, b, c}
\]

such that \( M_{\beta', b, c} \) is the conjunction

\[
\left( \bigwedge_{\beta} (\beta' \leq \beta) \land (\beta' - x \equiv_{a \geq \alpha} b) \land (\alpha \equiv_{a \geq \alpha} c) \right).
\]

A similar argument can be done when \( \lambda^t_x \) is \((t = \alpha - x) \land (\bigwedge_{\beta} \alpha \leq \beta) \land \lambda_x^i \land \lambda_\theta^i \) resp.\( (t = \alpha + \alpha' - x) \land (\bigwedge_{\beta} \alpha \leq \beta) \land \lambda_x^i \land \lambda_\theta^i \land \mu_\theta \).\]
Let \( L_i = b_i \cdot K_i \). Let us first construct \( \text{Max}_{K_i} \). This formula will contain no \( M_x \). If \( K_i = \{ b_i \} \) with \( b_i \in B_R \), then all the proof done before for \( L_i = \{ b_i \} \) can be repeated with \( x \) replaced by 0. Suppose that \( K_i = K \cdot K' \) and that \( \text{Max}_K(t, \Theta) \) and \( \text{Max}_{K'}(t, \Theta) \) are a disjunction of formulae \( M_t \land M_{\theta} \) and \( M'_t \land M'_{\theta} \) respectively. If \( M_t = (t = \alpha) \) and \( M'_t = (t = \alpha') \), then \( \text{Max}_{K_i}(t, \Theta) \) contains the conjunction \((t = \alpha + \alpha') \land M_{\theta} \land M'_{\theta} \). If \( M_t = (t = \infty) \) or \( M'_t = (t = \infty) \), then \( \text{Max}_{K_i}(t, \Theta) \) contains the conjunction \((t = \infty) \land M_{\theta} \land M'_{\theta} \). Suppose that \( K_i = K^+ \), then the maximum duration equals \( \infty \) if \( L \) contains a non null duration (see Lemma \ref{lem:max-inf}), and 0 otherwise. Thus \( \text{Max}_{K_i}(t, \Theta) \) is the formula \(( (t = \infty) \land \text{NonNull}_K(\Theta) ) \lor ( (t = 0) \land \neg \text{NonNull}_K(\Theta) ) \). Formula \( \text{Max}_{L_i}(t, x, \Theta) \) for \( L_i = b_i \cdot K_i \) can be easily constructed (as done before for \( K \cdot K' \)).

\[ \text{Proof. (of Proposition \ref{prop:main}).} \]

Let \( \gamma \) be a linear term and \( \sim \in \{<,\leq,>,\geq\} \). We have to show that there exists a \( B_{x,\Theta} \) formula \( \text{Duration}_{q,q'}(x, \Theta) \) such that for any valuation \( v \) and any clock value \( x_0 \), \( \text{Run}_q(x, v(\Theta)) \) is TRUE iff there exists an infinite run in \( A^v \) starting with \((q, x_0)\). Such a run exists iff for some \( q' \in Q \), there exist runs in \( R_{q,q'}(A^v, x_0) \) with arbitrarily large durations. As \( R_{q,q'}(A^v, x_0) = \bigcup_i R_i \), this is equivalent to say that some \( R_i \) contains runs with arbitrarily large durations. By Lemma \ref{lem:disj}, it follows that formula \( \text{Run}_q(x, \Theta) \) is equal to \( \bigvee_{q' \in Q} \bigvee_i \text{NonZeno}_L_i(x, \Theta) \).

\[ \text{Proof. (of Proposition \ref{prop:main}).} \]

Let \( \gamma \) be a linear term and \( \sim \in \{<,\leq,>,\geq\} \). We have to show that there exists a \( B_{x,\Theta} \) formula \( \text{Duration}_{q,q'}(x, \Theta) \) such that for any valuation \( v \) and any clock value \( x_0 \), \( \text{Duration}_{q,q'}(x_0, v(\Theta)) \) is TRUE iff there exists a run in \( R_{q,q'}(A^v, x_0) \) with duration \( t \sim v(\gamma) \).

(1) We begin with \( \sim \in \{<,\leq\} \). To test if there exists a run in \( R_{q,q'}(A^v, x_0) \) with duration \( t \sim v(\gamma) \) is equivalent to test that \( t_{\text{min}} \sim v(\gamma) \) with \( t_{\text{min}} \) being the minimum duration of runs in \( R_{q,q'}(A^v, x_0) \). By Lemma \ref{lem:min-simplify} the minimum duration for each \( R_i \) is expressed by formula \( \text{Min}_{L_i}(t, x, \Theta) \). This formula is of the form \( \mu_t \land \mu_x \land \mu_{\theta} \) with \( \mu_t \) equal to \( t = \alpha \) or \( t = \alpha - x \). Therefore \( \text{Duration}_{q,q'}(x, \Theta) \) is equal to \( \bigvee_i \text{Duration}_i \), where each \( \text{Duration}_i \) is obtained by modifying \( \text{Min}_{L_i} \) as follows: any formula \( \mu_t \) equal to \( t = \alpha \) (or \( t = \alpha - x \) resp.) is replaced by formula \( \alpha \sim \gamma \) (or \( \alpha - x \sim \gamma \) resp.).

(2) We now turn to \( \sim \in \{>,\geq\} \). The approach is similar but with the maximum (instead of minimum) duration. By Lemma \ref{lem:max-simplify} the maximum duration for each \( R_i \) is expressed by formula \( \text{Max}_{L_i}(t, x, \Theta) \). This formula is a disjunction of formulae \( M_t \land M_x \land M_{\theta} \) with \( M_t \) equal to \( t = \alpha \), \( t = \alpha - x \) or \( t = \infty \). It follows that \( \text{Duration}_{q,q'}(x, \Theta) \) is equal to \( \bigvee_i \text{Duration}_i \), where each \( \text{Duration}_i \) is obtained by modifying \( \text{Max}_{L_i} \) in the following way. If \( M_t \) equals \( t = \alpha \), \( t = \alpha - x \) or \( t = \infty \), then it is replaced by formula \( \alpha \sim \gamma \) or \( \alpha - x \sim \gamma \) respectively.

\[ \square \]

5. Conclusion

In this paper, we have completely studied the model-checking problem and the parameter synthesis problem of the logic PTCTL, an extension of TCTL with parameters, over one parametric clock discrete-timed automata. On the negative side, we showed that the model-checking problem is undecidable. The undecidability result needs equality in the logic. On the positive side, we showed that for the fragment F-PTCTL where the equality is not allowed, the model-checking problem becomes decidable and the parameter synthesis problem is solvable. Our algorithm is based on automata theoretic principles and an extension of
our method (see [5]) to express durations of runs of a timed automaton using Presburger arithmetic. With this approach, the model-checking problem and the parameter synthesis problem are syntactically translated into Presburger arithmetic which has a decidable theory and an effective quantifier elimination. The model checking problem is translated into a Presburger sentence inside which the Presburger decidability process looks for semantic inconsistencies between the parameters and the parametric clock. The parameter synthesis problem asks for which values of the parameters is a F-PTCTL formula true at a given configuration of the timed automaton. Thanks to Presburger quantifier elimination, this problem is solved by expressing the values of the parameters in terms of the operations +, ≤ and ≡ mod a, a ∈ N+.

To the best of our knowledge, this is the first work that studies the model-checking and parameter synthesis problems with parameters both in the model (timed automaton) and in the property (PTCTL formula). The problems solved in this paper are important as it is very natural to refer in the properties of the system to parameters appearing in the model of the system. We illustrated in the introduction the kind of properties that can be expressed and automatically verified in our framework.

Future works could be the following ones. A first work is to give the precise borderline between decidability and undecidability. Is the model-checking decidable for the logic PTCTL such that equality is forbidden in the operators ∃U¬α and ∀U¬α? No complexities issues are given in this paper and only the discrete time is considered. Presburger theory is decidable with the high 3ExpTime complexity. More efficient algorithms should be designed for particular fragments of F-PTCTL. The extension to dense timed models of the method proposed in this paper should be investigated.
