(Dated: February 25, 2022)

In the framework of an extended chromomagnetic model, we systematically study the mass spectrum of the S-wave $qQ\bar{q}Q$ tetraquarks. Their mass spectra are mainly determined by the color interaction. For the $qc\bar{c}c$, $fcb\bar{c}$ and $qb\bar{b}b$ tetraquarks, the color interaction favors the color-sextet $|qQ|^6(\bar{Q}Q)^6$ configuration over the color-triplet $|qQ|^3(\bar{Q}Q)^3$ one. But for the $qc\bar{b}b$ tetraquarks, the color-triplet configuration is favored. We find no stable states which lie below the thresholds of two pseudoscalar mesons. The lowest axial-vector states with the $qQ\bar{b}b$ flavor configuration may be narrow. They lie just above the thresholds of two pseudoscalar mesons, but cannot decay into these channels because of the conservation of the angular momentum and parity.

I. INTRODUCTION

Searching for the exotic states is an important and challenging topic in hadron physics. In the past two decades, we have witnessed tremendous progresses in this area. In 2003, the first charmoniumlike state $X(3872)$ was observed by the Belle Collaboration [1], and later confirmed by the CDF [2], D0 [3], BABAR [4], LHCb [5], CMS [6], and BESIII [7] Collaborations. Its quantum number is $I^GJ^{PC}=0^+1^{++}$ [8]. Since then, lots of charmoniumlike and bottomoniumlike states are found. They are called $XYZ$ states. Many of them do not fit into the conventional charmonium or bottomonium spectrum in the quark model. In particular, the charged charmoniumlike and bottomoniumlike states like $Z_c(3900)$ [9, 10], $Z_c(3885)$ [11, 12], $Z_b(4020)$ [13], $Z_b(4025)$ [14], $Z_{cs}(3985)$ [15], $Z_{cs}(4000)$ and $Z_{cs}(4020)$ [16], $Z_b(10610)$ and $Z_b(10650)$ [17] contain at least four quarks. They are candidates of exotic structures like the compact tetraquark [18–22], the molecule [23–29], the hybrid meson [30, 31], and so on. Interested readers may refer to Refs. [32–41] for more details.

Besides the charmoniumlike and bottomoniumlike states, various open heavy flavor exotic states have been observed recently. In 2016, the D0 Collaboration reported the observation of the $X(3568)$ state in the $B^0D^{\pm}\pi^\mp$ channel [42]. It was very likely a $us\bar{d}b$ or $ds\bar{u}b$ tetraquarks since it lies about 200 MeV below the $BK$ threshold [43]. However, the subsequent search of the LHCb Collaboration did not confirm this state [44]. In 2020, the LHCb Collaboration observed two resonances in the $D^-K^+$ channel with spin-0 and spin-1 [45, 46], whose minimal quark contents are $uds\bar{c}$. Recently, the LHCb Collaboration observed an narrow state in the $D^0D^0\pi^+$ mass spectrum just below the $D^{*+}D^0$ threshold [47, 48]. This is the first doubly charmed tetraquark $T_{cc}^+$ observed in experiment. Moreover, in 2020, the LHCb collaboration observed a narrow structure and a wide structure in the $J/\psi$-pair invariant mass spectrum in the range of 6.2–7.2 GeV, which could be all-charm hadrons [49].

At this stage, it is natural to expect that the triply charmed tetraquark(s) may be observed in the very near future. For the triply charmed system, a molecule configuration requires the exchange of a $D$ meson. The corresponding interaction range is $\sim 0.1$ fm, which is a typical scale of the compact tetraquark. From another point of view, the $D$-meson exchange interaction is highly suppressed in the typical scale of the molecule ($\sim$ fm). In other words, the molecule interpretation is not favored for the triply heavy system. If a $qq\bar{c}\bar{c}$ state is observed in experiment, it is very likely a compact tetraquark state.

However, the theoretical study of this system is relatively scarce [19, 50–58]. In Ref. [52], Chen et al. found that some axial-vector $ccb\bar{q}$ states lie below the $B_sD(s)_s$ thresholds, which are stable against the strong decay. A lattice study performed by Junnarkar et al. [54] gives similar results. They found that the axial-vector $us\bar{d}b$ and $sc\bar{b}b$ lie below their thresholds by $6 \pm 11$ MeV and $8 \pm 3$ MeV respectively. However, a recent study by Lü et al. [58] predicted that the corresponding states are about several hundred MeV higher. More theoretical and experimental studies are needed to have a better understanding of these systems.

For the triply heavy tetraquarks, the interaction is provided by the gluon exchange and string confinement. The resulting interactions include the spin-independent Coulomb-type interaction, linear confinement and spin-dependent chromomagnetic interaction, tensor interaction and spin-orbit interaction. When focusing on the $S$-wave states, the tensor and spin-orbit interactions can be neglected. Furthermore, we can simplify the model by integrating out spatial part of the interaction. Then the interaction becomes

$$-\sum_{i<j} a_{ij} F_i \cdot F_j - \sum_{i<j} v_{ij} S_i \cdot S_j F_i \cdot F_j.$$  (1)

This interaction gives good account of the $S$-wave mesons and baryons [59]. In this work, we use this interaction.
to study the triply heavy tetraquarks. The paper is organized as follows. In Sec. II, we introduce the extended chromomagnetic model and construct the wave function bases for the triply heavy tetraquarks. Then we discuss the numerical results in Sec. III. We conclude in Sec. IV.

II. THE EXTENDED CHROMOMAGNETIC MODEL

For the $S$-wave tetraquark system, we consider the chromomagnetic model. The Hamiltonian reads [59–67]

$$H = \sum_i m_i + H_{CE} + H_{CM}$$

where $m_i$ is the effective mass of $i$th constituent quark which consists of the constituent quark mass, the kinetic energy, and so on, $H_{CE}$ is the colorelectric (CE) interaction which includes the color linear confinement and Coulomb-type interaction [59, 64–67]

$$H_{CE} = -\sum_{i<j} a_{ij} F_i \cdot F_j,$$

and $H_{CM}$ is the chromomagnetic (CM) interaction from the one-gluon-exchange (OGE) [19, 40, 52, 68–71]

$$H_{CM} = -\sum_{i<j} v_{ij} S_i \cdot S_j F_i \cdot F_j.$$

The coupling constants $a_{ij}$ and $v_{ij}$ depend on the spatial wave function and the constituent quark masses. $S_i = \sigma_i/2$ and $F_i = \lambda_i/2$ are the quark spin and color operators. For the antiquark,

$$S_\bar{q} = -S^{*}_q, \quad F_\bar{q} = -F^{*}_q.$$  

Since

$$\sum_{i<j} (m_i + m_j) F_i \cdot F_j = \left( \sum_i m_i F_i \right) \cdot \left( \sum_i F_i \right) - \frac{4}{3} \sum_i m_i,$$

and the total color operator $\sum_i F_i$ nullifies any color-singlet physical state, we introduce the quark pair mass parameter

$$m_{ij} = (m_i + m_j) + \frac{4}{3} a_{ij},$$

to combine the effective quark mass $m_i$ and the color interaction strength $a_{ij}$. Then we can rewrite the model Hamiltonian as [59, 65–67]

$$H = -\frac{3}{4} \sum_{i<j} m_{ij} V^C_{ij} - \sum_{i<j} v_{ij} V^CM_{ij},$$

where

$$V^C_{ij} = F_i \cdot F_j,$$  

and

$$V^CM_{ij} = S_i \cdot S_j F_i \cdot F_j$$

are the color and CM interactions between quarks, respectively. Here, $m_{ij}$ and $v_{ij}$ are unknown parameters. In Ref. [59], we have used the conventional mesons and baryons to fit them. More precisely, we used the pseudoscalar and vector mesons to extract the parameters $m_{q\bar{q}}$ and $v_{q\bar{q}}$, and used the light and singly heavy baryons to fit the $\{m_{q\bar{q}}, v_{q\bar{q}}\}$ with at most one heavy quark, estimated the $m_{QQ}$ and $v_{QQ}$ through a quark model consideration. Their values are listed in Table I. With these parameters, we reproduce the meson and baryon masses with errors mostly within 10 MeV (The only exception is the $\Sigma$ baryon, whose deviation is 15 MeV.). We also obtained the $\Xi_{cc}$ baryon mass very close to the LHCb Collaboration’s measurement ($M_{\Xi_{cc}} = 3633.3 \pm 9.3$ MeV versus $M_{\exp} = 3621.55 \pm 0.23 \pm 0.30$ MeV) [72, 73]. In Ref. [66], we used these parameters to study the fully heavy tetraquark systems. We found that for the ground states, the color sextet component is more important than the color triplet one, which is consistent with the dynamical calculations [74, 75]. We also studied the hidden-charm pentaquark states, and successfully reproduced the four $P_1$ states, $P_1(4312)$, $P_1(4380)$, $P_1(4440)$, and $P_1(4450)$ [76, 77] with these parameters [65]. In this work, we use the same set of parameters to estimate the masses of the $S$-wave $q\bar{q}QQ$ tetraquarks.

A. Wave function

Before calculating the tetraquark masses, we need to construct their wave functions. In principle, the total wave function is a direct product of the orbital, color, spin and flavor wave functions. In this work, we only consider the $S$-wave states, the orbital wave function is always symmetric. In the $qq\bar{q}\bar{q}$ configuration, we can construct the following color-spin wave functions $\{\alpha_i\}$

1. $J^P = 0^+$:

$$\alpha_1 = \left| (q_1 q_2)_1 \bar{q} q_4 \bar{q}_4 \bar{q}_4 \right|_{1/2},$$

$$\alpha_2 = \left| (q_1 q_2)_0 \bar{q}_4 q_4 \bar{q}_4 \bar{q}_4 \right|_{1/2},$$

$$\alpha_3 = \left| (q_1 q_2)_1 \bar{q}_4 q_4 \bar{q}_4 \right|_{1/2},$$

$$\alpha_4 = \left| (q_1 q_2)_0 \bar{q}_4 q_4 \bar{q}_4 \right|_{1/2}.$$

2. $J^P = 1^+$:

$$\alpha_1 = \left| (q_1 q_2)_1 \bar{q} q_4 \bar{q}_4 \bar{q}_4 \right|_{1/1},$$

$$\alpha_2 = \left| (q_1 q_2)_1 \bar{q}_4 q_4 \bar{q}_4 \bar{q}_4 \right|_{1/1},$$

$$\alpha_3 = \left| (q_1 q_2)_1 \bar{q}_4 q_4 \bar{q}_4 \right|_{1/1},$$

$$\alpha_4 = \left| (q_1 q_2)_0 \bar{q}_4 q_4 \bar{q}_4 \right|_{1/1}.$$

\end{align*}
\]

where the superscript 3, 3, 6 or 6 denotes the color, and the subscript 0, 1 or 2 denotes the spin.

Next we consider the flavor wave functions. According to symmetric properties of the two antiquarks, the triply heavy tetraquarks can be divided into two categories. The $qQ\bar{c}\bar{b}$ tetraquarks are not constrained by the Pauli principle, thus all the preceding color-spin wave functions are allowed. On the other hand, the $qQ\bar{c}\bar{c}$ and $qQ\bar{b}\bar{b}$ tetraquarks have symmetric flavor wave functions over the two antiquarks, thus the color-spin wave functions must be asymmetric over the two antiquarks. More precisely, the bases for the $qQ\bar{c}\bar{c}$ and $qQ\bar{b}\bar{b}$ tetraquarks are \{\alpha_2^3, \alpha_4^3\}, \{\alpha_2^4, \alpha_4^4\} and \{\alpha_2^1\}.

Table I lists the masses and eigenvectors of the triply heavy tetraquarks.

III. NUMERICAL RESULTS

A. The $nc\bar{c}\bar{c}$ and $qb\bar{c}\bar{c}$ systems

First we consider the $nc\bar{c}\bar{c}$ and $qb\bar{c}\bar{c}$ tetraquarks. Their masses and eigenvectors are listed in Table II. For simplicity, we will use $T(qQ\bar{Q}Q, m, J^P)$ to denote the $qQ\bar{Q}Q$ tetraquarks in the following. The isospin of the tetraquarks can be easily identified with either $q = u$ or $q = s$. Here we assume that the SU(2) flavor symmetry is exact and $n = \{u, d\}$. We plot their relative position in Fig. 1 along with the corresponding meson-meson thresholds. From the figure, we can easily see that the quantum number of the ground states are $J^P = 0^+$ in both cases. They are $T(nc\bar{c}\bar{c}, 4936.7, 0^+)$ and $T(sc\bar{c}\bar{c}, 5040.1, 0^+)$, respectively. On the other hand, the highest mass states have quantum number $J^P = 2^+$. Comparing to the thresholds, we find that all states are above the meson-meson thresholds and can decay through S-wave. They may all be broad states [68]. The lowest axial-vector states $T(nc\bar{c}\bar{c}, 4908.1, 1^+)$ and $T(sc\bar{c}\bar{c}, 5069.2, 1^+)$ lie just above the $D_{(s)}J/\psi$ threshold. Thus they might be relatively narrow compared to other states.

Besides the masses, the eigenvectors also provide important information of the tetraquarks. The color configurations of the tetraquarks can be of $|(q_1 q_2)^6\bar{c}\bar{c}\bar{c}\bar{c}\bar{c}|$ or $|(q_1 q_2)^3\bar{c}\bar{c}\bar{c}\bar{c}\bar{c}|$. For simplicity, we denote them as $6_{c} \otimes 6_{c}$ and $3_{c} \otimes 3_{c}$. From Table II, we find that the ground states of the $nc\bar{c}\bar{c}$ and $sc\bar{c}\bar{c}$ tetraquarks are both dominated by the color-sextet components. The

| System $J^{P}$ | Mass | $D_{s}B_{c}$ | $D_{s}B_{c}^{*}$ | $D_{1}B_{s}$ | $D_{1}B_{s}^{*}$ |
|----------------|------|----------------|----------------|----------------|-----------------|
| $sb\bar{c}$ 0$^{+}$ | 8300.5 | $\times$ | 1 | 8538.7 | 2.6 | 1 |
| 1$^{+}$ | 8324.8 | $\times$ | $\times$ | 1 | 8521.9 | 0.2 | 1.3 | 1 |
| 2$^{+}$ | 8569.1 | 1 |

$T(nc\bar{c}, 4936.7, 0^{+})$ has 66.7% of the $6_{c} \otimes \bar{6}_{c}$ component and the $T(sc\bar{c}, 5040.1, 0^{+})$ has 66.6%. This is very similar to the fully charm tetraquarks $[66, 74, 75, 79]$. In the one-gluon-exchange (OGE) model, the color interactions are attractive inside $(q_{1}q_{2})^{3c}/(\bar{q}_{3}\bar{q}_{4})^{3c}$ and repulsive inside $(q_{1}q_{2})^{6c}/(\bar{q}_{3}\bar{q}_{4})^{6c}$. However, the attractions between $(q_{1}q_{2})^{6c}$ and $(\bar{q}_{3}\bar{q}_{4})^{6c}$ is much stronger than that between $(q_{1}q_{2})^{3c}$ and $(\bar{q}_{3}\bar{q}_{4})^{3c}$. In our cases, the two competing effects result in the lower mass of the color-sextet configurations. More precisely,

$$
\langle H_{C} (qc\bar{c}) \rangle = -\frac{3}{4} \langle m_{qc} V_{12}^{C} + m_{cc} V_{14}^{C} + m_{qc} (V_{13}^{C} + V_{14}^{C}) + m_{cc} (V_{23}^{C} + V_{24}^{C}) \rangle \\
= m_{qc} + m_{cc} - \frac{3}{2} \delta m \langle V_{12}^{C} + V_{14}^{C} \rangle \\
= m_{qc} + m_{cc} + \delta m \begin{pmatrix} -1 & 0 \\ 0 & +2 \end{pmatrix}
$$

(14)

where $\delta m = (m_{qc} + m_{cc} - m_{qc} - m_{cc})/4$. Inserting the
parameters in Table I, we have
\[ \delta m(uc\bar{c}\bar{c}) = 52.43 \text{ MeV}, \]
\[ \delta m(sc\bar{c}\bar{c}) = 52.63 \text{ MeV}. \]

Similar to the fully charm cases, the color interaction renders the \( 6_c \otimes 6_c \) configuration more stable than the \( \bar{3}_c \otimes \bar{3}_c \) one. We also find that the color interaction does not mix the two color configurations. This is because the two antiquarks are identical \([67, 74]\). However, the two color configuration will mix due to the CM interaction
\[
\langle H_{CM}(qc\bar{c}\bar{c}) \rangle = \begin{pmatrix}
\frac{1}{3}(v_{q\bar{c}} + v_{c\bar{c}}) & -\sqrt{\frac{2}{3}}(v_{q\bar{c}} + v_{c\bar{c}}) \\
-\sqrt{\frac{2}{3}}(v_{q\bar{c}} + v_{c\bar{c}}) & \frac{1}{3}(v_{q\bar{c}} + v_{c\bar{c}}) - \frac{1}{3}(v_{q\bar{c}} + v_{c\bar{c}})
\end{pmatrix}
\approx \frac{v_{q\bar{c}} + v_{c\bar{c}}}{2}
\]
\[\frac{1}{2} \left( \frac{1}{2} - \frac{1}{2} \right) \]
where we have used \( v_{q_1,q_2} = v_{q_1,q_2} \approx 2/3 \) in the last line \[59\]. Here, \( (v_{q\bar{c}} + v_{c\bar{c}})/2 = 95.57 \text{ MeV and } (v_{q\bar{c}} + v_{c\bar{c}})/2 = 96.50 \text{ MeV.} \) The diagonal part of the CM interaction favors the \( 3_c \otimes 3_c \) configuration by approximately 75 MeV. However, Eq.(14) indicates that the color interaction disfavors the \( 3_c \otimes 3_c \) configuration by approximately 150 MeV. Thus the ground states of the scalar \( q\bar{c}\bar{c} \) and \( sc\bar{c}\bar{c} \) tetraquarks are dominated by the \( 6_c \otimes 6_c \), while the higher scalar states mostly consist of \( \bar{3}_c \otimes 3_c \) component.

There are three bases for the axial-vector states, namely \( |(bc)_{0}^{3}(c\bar{c})_{0}^{3}\rangle, |(bc)_{1}^{3}(c\bar{c})_{1}^{3}\rangle \) and \( |(bc)_{0}^{3}(c\bar{c})_{1}^{3}\rangle \). In these bases, we have
\[
\langle H_{C}(qc\bar{c}\bar{c}) \rangle = m_{q\bar{c}} + m_{c\bar{c}} + \delta m
\begin{pmatrix}
-1 & 0 & 0 \\
0 & +2 & 0 \\
0 & 0 & +2
\end{pmatrix}
\]  

\[\text{The color interaction splits the three bases into two energy bands. The } 6_c \otimes 6_c \text{ configuration is more stable than the } 3_c \otimes 3_c \text{. The CM interaction further splits the two bands into the three bands structure in Fig. 1. As a consequence, the lightest axial-vector states of both } nc\bar{c}\bar{c} \text{ and } sc\bar{c}\bar{c} \text{ tetraquarks have more than 80% of the } 6_c \otimes 6_c \text{ component. Combining the scalar and axial-vector cases, we can conclude that the tetraquark spectrum is dominantly determined by the color interaction, and the CM interaction contributes to the finer structures.}

The eigenvectors can also be used to study the decay properties of the tetraquarks. We can transform the wave functions into the \( qq \otimes q\bar{q} \) configuration. The corresponding color configuration can be either of \( |(qq)_{1}^{3}(q\bar{q})_{1}^{3}\rangle \) or \( |(qq)_{0}^{3}(q\bar{q})_{0}^{3}\rangle \). The former one can easily decay into two \( S \)-wave mesons in \( S \) wave (the so-called “Okubo-Zweig-Iizuka- (OZI)-superallowed” decays), while the latter one can fall apart only through gluon exchange. Following Refs. \([68, 69, 80]\), we only consider the “OZI-superallowed” decays. In Tables III–IV, we transform the eigenvectors of the \( qc\bar{c}\bar{c} \) tetraquarks into the \( q\bar{c}\bar{c} \) configuration. For simplicity, we only present the color-singlet components, and we rewrite the bases as a direct product of two mesons. For each decay channel, the decay width is proportional to the square of the coefficient \( c_i \) of the corresponding component in the eigenvectors, and also depends on the phase space. For two body decay through \( L \)-wave, the partial decay width reads \[65, 81\]
\[\Gamma_i = \gamma_i \alpha \frac{m^{2L+1}}{m^{2L}} |c_i|^2, \]
where \( \gamma_i \) is a quantity determined by the decay dynamics, \( \alpha \) is an effective coupling constant, \( k \) is the momentum of the final states in the rest frame of the initial state, and \( m \) is the mass of the initial state. In this work, the \( (k/m)^2 \) is always of \( \mathcal{O}(10^{-2}) \) or even smaller. Thus we will only consider the \( S \)-wave decays. Next we consider the \( \gamma_i \).

Generally, \( \gamma_i \) depends on the spatial wave functions of the initial tetraquark and final mesons, which are different for each decay process. In the quark model, the spatial wave functions of the ground state scalar and axial-vector meson are the same \[82, 83\]. Thus for each tetraquark, we have
\[\gamma_{M_1M_2} = \gamma_1 \gamma_2 \gamma_{M_1M_2} = \gamma_1 \gamma_2 \gamma_{M_1M_2} \]
\[\text{where } M_i \text{ and } M_i^* \text{ denote the pseudoscalar and axial-vector mesons. With the eigenvectors obtained, we calculate the value of } k \cdot |c_i|^2 \text{ and the relative widths for the } qc\bar{c}\bar{c} \text{ decays, as shown in Tables V–VIII. Their ground states can easily decay into } D_{s}(s)J/\psi \text{, thus may be broad states \[68\]. The higher scalar states, } T(nc\bar{c}\bar{c}, 5185.3, 0^+) / T(sc\bar{c}\bar{c}, 5290.6, 0^+) \text{, can decay to } D_{s}(s)J/\psi \text{ and } D_{s}(s)J/\psi \text{ through } S \text{-wave, with relative decay width ratios}
\[\frac{\Gamma[T(nc\bar{c}\bar{c}, 5185.3, 0^+) \to D_{s}^*J/\psi]}{\Gamma[T(nc\bar{c}\bar{c}, 5185.3, 0^+) \to DJ/\psi]} \sim 6.8, \]
\[\text{and}
\[\frac{\Gamma[T(sc\bar{c}\bar{c}, 5290.6, 0^+) \to D_{s}^*J/\psi]}{\Gamma[T(sc\bar{c}\bar{c}, 5290.6, 0^+) \to DJ/\psi]} \sim 7.0. \]

The dominant decay modes are the \( D_{s}(s)J/\psi \) final states. Next we consider the axial-vector states. The \( T(nc\bar{c}\bar{c}, 5135.3, 1^+) \text{ decay dominantly to } D_{s}^*\eta_c \text{ and } DJ/\psi \text{, with}
\[\Gamma[D_{s}^*J/\psi : \Gamma_{D_{s}^*\eta_c} : \Gamma_{DJ/\psi} \sim 0.004 : 1.3 : 1. \]
\[\text{And for } T(nc\bar{c}\bar{c}, 5154.0, 1^+)
\[\Gamma[D_{s}^*J/\psi : \Gamma_{D_{s}^*\eta_c} : \Gamma_{DJ/\psi} \sim 20.7 : 1.3 : 1. \]

Its dominant decay mode is \( D_{s}^*J/\psi \). The decay property of the \( sc\bar{c}\bar{c} \) tetraquarks is similar the \( nc\bar{c}\bar{c} \) tetraquarks.

Replacing the charm quark by a bottom quark, we get the \( nb\bar{c}\bar{c} \) and \( sb\bar{c}\bar{c} \) tetraquarks. We list their masses
and eigenvectors in Table IX and plot their relative position in Fig. 2, along with the possible decay channels. Since the $B_s^*$ meson has not been observed, we use the Godfrey-Isgur (GI) model’s prediction $M_{B_s^*} = 6338$ MeV [78] to estimate the meson-meson thresholds. The $qbc\bar{c}$ tetraquarks are very similar to the $qc\bar{c}$ tetraquarks. The ground states are both scalar. They are $T(nb\bar{c}\bar{c}, 8199.1, 0^+)$ and $T(sbc\bar{c}, 8300.5, 0^+)$, whose color configurations are $6_c \otimes \bar{6}_c$ as well ($> 80\%$). The lightest axial-vector states, $T(nb\bar{c}\bar{c}, 8217.5, 1^+)$ and $T(sbc\bar{c}, 8324.8, 1^+)$ are also dominated by $6_c \otimes \bar{6}_c$ component ($> 90\%$). All higher states mainly consist of $3_c \otimes 3_c$ component.

The decay properties of the $qbc\bar{c}$ tetraquarks can be found from Tables X–XV. Similar to the $qc\bar{c}$ tetraquarks, the two lowest states are just above their $S$-wave decay channels, while all other states are above meson-meson thresholds. The higher scalar states can decay into $D_s^{(*)}B_c^*$ and $\bar{D}_sB_c$ channels with into comparable partial widths

$$\Gamma \left[ T(nb\bar{c}\bar{c}, 8444.8, 0^+) \rightarrow D_s^{(*)}B_c^* \right] \sim 2.3, \quad (25)$$

and

$$\Gamma \left[ T(sbc\bar{c}, 8538.7, 0^+) \rightarrow D_s^{(*)}B_c^* \right] \sim 2.6. \quad (26)$$

For the highest axial-vector states, we have

$$\Gamma_{D_sB_c^*} : \Gamma_{D_sB_c^*} : \Gamma_{D_sB_c^*} \sim 23.8 : 10.7 : 1 \quad (27)$$

for $T(nb\bar{c}\bar{c}, 8454.5, 1^+)$ and

$$\Gamma_{D_sB_c^*} : \Gamma_{D_sB_c^*} : \Gamma_{D_sB_c^*} \sim 15.7 : 5.1 : 1 \quad (28)$$

for $T(sbc\bar{c}, 8553.3, 1^+)$. The $D_s^{(*)}B_c^*$ and $\bar{D}_sB_c$ modes are more important. However, for the second higher axial-vector states of $qbc\bar{c}$ tetraquarks, the partial decay widths of $D_s^{(*)}B_c^*$ and $\bar{D}_sB_c$ modes are comparable, though the first mode is relatively smaller.

**B. The $qbb\bar{b}$ and $qcb\bar{b}$ systems**

Next we consider the $qbb\bar{b}$ and $qcb\bar{b}$ tetraquarks. Their masses and eigenvectors are listed in Tables XVI–XVII. Their relative position are plotted in Figs. 3–4. By replacing the three charm quark/antiquarks of the $qc\bar{c}$ tetraquarks into bottom quark/antiquarks, we can obtain the $qbb\bar{b}$ tetraquarks. Thus we expect that the two systems share some similar properties. Specifically, the quantum numbers of the lowest and highest $qbb\bar{b}$ tetraquarks are $J^P = 0^+$ and $J^P = 2^+$ respectively. Their ground states are $T(nbb\bar{b}, 14706.1, 0^+)$ and $T(sb\bar{b}, 14793.1, 0^+)$, whose dominant color configurations are $6_c \otimes 6_c$ ($> 85\%$). The color triplet component is mostly in the higher scalar states. The axial-vector states are similar. The $6_c \otimes 6_c$ component is mostly in the lightest states ($> 90\%$), and the $3_c \otimes 3_c$ components are mostly in the higher states. Just like the $qc\bar{c}$ cases, the underlining reason is the color interaction

$$\langle H_C (qbb\bar{b}) \rangle = m_{qb} + m_{\bar{b}} - \frac{3}{2} \delta m' \left( V_{C2}^2 + V_{C4}^2 \right) \quad (29)$$

where

$$\delta m' = \frac{m_{qb} + m_{bb} - m_{\bar{b}b} - m_{\bar{b}b}}{4} \sim 45 \text{ MeV}. \quad (30)$$
FIG. 3. Mass spectra of the $n\bar{b}b\bar{b}$ and $s\bar{b}b\bar{b}$ tetraquark states. The dotted lines indicate various meson-meson thresholds. The masses are all in units of MeV.
FIG. 4. Mass spectra of the $nc\bar{b}\bar{b}$ and $sc\bar{b}\bar{b}$ tetraquark states. The dotted lines indicate various meson-meson thresholds. Here the predicted mass $M_{B_c} = 6338$ MeV of Godfrey et al. [78] is used. The masses are all in units of MeV.

| $1^+$ | 14804.5 | $\times$ | $\times$ | $\times$ | 14929.2 | 2.3 | 144.9 | 140.7 |
| $2^+$ | 14956.5 | 249.2 |

TABLE XXII. The partial width ratios for the $nb\bar{b}$ tetraquarks. For each state, we choose one mode as the reference channel, and the partial width ratios of the other channels are calculated relative to this channel. The masses are all in unit of MeV.

| System | $J^P$ | Mass | $B^*\Upsilon$ | $B^*\eta_b$ | $BY$ | $B\eta_b$ |
|--------|-------|------|-------------|-------------|--------|-------------|
| $nb\bar{b}$ | $0^+$ | 14706.1 | $\times$ | 1 | 14850.9 | 1.7 | 1 |
| $1^+$ | 14712.1 | $\times$ | $\times$ | $\times$ | 14845.1 | 0.1 | 1.4 | 1 |
| $2^+$ | 14871.8 | 1 |

TABLE XXIII. The partial width ratios for the $s\bar{b}\bar{b}$ tetraquarks. For each state, we choose one mode as the reference channel, and the partial width ratios of the other channels are calculated relative to this channel. The masses are all in unit of MeV.

| System | $J^P$ | Mass | $B^*\Upsilon$ | $B^*\eta_b$ | $BY$ | $B\eta_b$ |
|--------|-------|------|-------------|-------------|--------|-------------|
| $s\bar{b}\bar{b}$ | $0^+$ | 14793.1 | $\times$ | 1 | 14936.2 | 1.8 | 1 |
| $1^+$ | 14804.5 | $\times$ | $\times$ | $\times$ | 14929.2 | 0.02 | 1.03 | 1 |
| $2^+$ | 14956.5 | 1 |

Note that the $\langle V^C_1 + V^C_2 \rangle$ is diagonal in the $6_c \otimes 6_c$ and $3_c \otimes 3_c$ color bases, with matrix elements 2/3 and $-4/3$ respectively. Thus the $6_c \otimes 6_c$ configuration is favored.

The $q\bar{c}\bar{b}$ tetraquarks turn out to be quite different from the $q\bar{b}\bar{b}$ tetraquarks. The quantum number of the highest states becomes $J^P = 0^+$. For the

TABLE XXVI. The values of $k\cdot|c_i|^2$ for the $n\bar{c}b\bar{b}$ tetraquarks (in unit of MeV).

| System | $J^P$ | Mass | $B^*_sB^*_c$ | $B^*_bB_c$ | $B_sB^*_c$ | $B_sB_c$ |
|--------|-------|------|---------------|-------------|------------|----------|
| $n\bar{c}b\bar{b}$ | $0^+$ | 11581.7 | × | 160.9 | 11694.9 | 246.9 | 8.4 |
| | $1^+$ | 11582.2 | × | × | × | 11624.7 | × | 54.2 | 36.7 |
| | | 11586.6 | × | 21.9 | 46.0 | 11570.1 | × | |

$nc\bar{b}\bar{b}$ tetraquarks, the lightest axial-vector state lies only 0.5 MeV above the lightest scalar state. And the ground state of the $sc\bar{b}\bar{b}$ tetraquarks has quantum number $J^P = 1^+$. Moreover, the dominant color configuration of the lower mass states becomes $3_c \otimes 3_c$. For example, the $T(n\bar{c}b\bar{b}, 11581.7, 0^+)$ has 74% of $3_c \otimes 3_c$ component, and the $T(sc\bar{b}\bar{b}, 11675.1, 0^+)$ has 70%. We again resort to the color interaction

$$\langle H_C(q\bar{c}b\bar{b}) \rangle = m_{qb} + m_{cb} - \frac{3}{2} \delta m'' \langle V_{12}^C + V_{34}^C \rangle$$  (31)

TABLE XXVII. The values of $k\cdot|c_i|^2$ for the $sc\bar{b}\bar{b}$ tetraquarks (in unit of MeV).

| | $1^+$ | 11673.3 | × | × | × | 11722.2 | × | 1.2 | 1 |
| | | 11746.3 | × | 0.4 | 1 | 11750.2 | × | |

where

$$\delta m'' = \frac{m_{qc} + m_{bb} - m_{qb} - m_{cb}}{4}$$.  (32)

Here $\delta m'' = -6.5$ MeV for $q = n$, and $\delta m'' = -3.1$ MeV for $q = s$. The small negative values indicate that the $3_c \otimes 3_c$ configuration has slightly lower mass. The CM interaction

$$\langle H_{CM} (q\bar{c}b\bar{b}) \rangle$$

$$\begin{pmatrix}
\frac{1}{3} (v_{qc} + v_{bh}) \\
-\frac{\sqrt{3}}{3} (v_{qb} + v_{cb}) \\
-\frac{\sqrt{3}}{3} (v_{qc} + v_{bh}) - \frac{1}{3} (v_{qb} + v_{cb})
\end{pmatrix}$$  (33)

also favors the $3_c \otimes 3_c$ configuration. Thus for both the scalar and the axial-vector states, the lower mass states are dominated by the $3_c \otimes 3_c$ components, while the higher mass states have more $6_c \otimes 6_c$ components.

Before concluding this section, we would like to compare the present results with that of Refs. [66, 67]. It is interesting to note that the $q\bar{c}b\bar{b}$ tetraquarks (as well
as the \( q\bar{c}\bar{c} \) and \( q\bar{b}\bar{b} \) tetraquarks) are very similar to the fully heavy \( c\bar{b} \) tetraquarks, while the \( q\bar{c}\bar{b} \) tetraquarks are more like the doubly heavy tetraquarks. This is quite natural since that the triply heavy tetraquarks are intermediate states between the doubly and fully heavy tetraquarks. The reason is \( m_\eta \ll m_c \ll m_b \). A detailed dynamical study of the dependence of the spectrum and wave function with respect to the quark masses would be very important for decoding the nature of tetraquarks [84, 85].

Next we consider their decay properties. We transform the eigenvectors of the \( q\bar{b}\bar{b} \) (\( q\bar{c}\bar{b} \)) tetraquarks into the \( q\bar{b} \otimes \bar{b} \) (\( q\bar{c} \otimes \bar{b} \)) configuration, and calculate the values of \( k \cdot |c_i|^2 \) and partial width ratios of all possible decay channels. The corresponding results are listed in Tables XVIII–XXIX. We find six states which cannot decay into two mesons through \( S \)-wave. They are \( T(n\bar{b}b\bar{b}, 14712.1, 1^+) \), \( T(s\bar{b}b\bar{b}, 14804.5, 1^+) \), \( T(n\bar{c}b\bar{b}, 11582.2, 1^+) \), \( T(n\bar{c}b\bar{b}, 11651.7, 2^+) \), \( T(s\bar{c}b\bar{b}, 11673.3, 1^+) \) and \( T(s\bar{c}b\bar{b}, 11750.2, 2^+) \). Because of the conservation of the angular momentum and parity, their decays into the thresholds below them must be of higher wave (\( D \)-wave for example), which are highly suppressed. Thus we expect them to be narrow.

However, we need to bear in mind that our model is an oversimplified one. The dynamical effects are not included explicitly, but rather concealed in the interaction strengths \( \{m_{ij}, v_{ij}\} \). In the present work, we fit them from the conventional mesons and baryons. But they may be altered in the tetraquarks because of their wave function dependence. Nonetheless, even if the masses of these states are pushed upward above their \( S \)-wave channels, their phase spaces are still relatively small. Thus their decay widths are still smaller compared to those of other states. A dynamical calculation may help settle this issue. We hope the future experiments can search for these states.

### C. The \( q\bar{c}\bar{b} \) and \( q\bar{b}\bar{b} \) systems

Now we turn to the systems with two different heavy antiquarks. They are not constrained by Pauli principle. The mass spectra and eigenvectors are listed in Tables XXX–XXXI. We also transform their eigenvectors into the \( q\bar{c} \otimes \bar{Q}b \) and \( q\bar{b} \otimes Q\bar{b} \) configurations, as shown in Tables XXXII–XXXV. From these tables, we see that some eigenstates couple very strongly with two \( S \)-wave mesons. Taking \( n\bar{b}\bar{c} \) tetraquarks as example, the lowest eigenstate

\[
T(n\bar{b}c\bar{b}, 11293.4, 0^+) = 0.98341\bar{D}\eta_b + \cdots
\]  

This state couples almost completely (96.7%) to the \( \bar{D}\eta_b \) scattering state. Thus it may be very broad and hid in the continuum. Note that this kind of state also exists in the calculation of the hidden charm tetraquarks and pentaquarks, where the lower mass state couples strongly to a heavy charmonium and a light hadron [19, 65, 86]. Moreover, the \( T(n\bar{b}c\bar{b}, 11314.8, 1^+) \) and \( T(n\bar{b}c\bar{b}, 11392.4, 1^+) \) states couple very strongly to \( \bar{D} \bar{T} \) and \( \bar{D}^*\eta_b \) channels. Both the \( T(n\bar{b}c\bar{b}, 11438.6, 0^+) \), \( T(n\bar{b}c\bar{b}, 11446.6, 1^+) \) and \( T(n\bar{b}c\bar{b}, 11453.9, 2^+) \) couple very strongly to \( \bar{D}^*\bar{T} \). They may be scattering states.

To draw a definite conclusion, dynamical studies like the complex scaling methods [87, 88] are needed, which is beyond the present work. For clarity, we add a fifth column in Tables XXX–XXXI to indicate these scattering states.

We plot the relative position of the \( q\bar{c}\bar{b} \) and \( q\bar{b}\bar{b} \) tetraquarks in Figs. 5–6. For comparison, we also plot the possible scattering states. They are marked with a dagger (\( \dagger \), along with the proportion of their dominant components. We can easily see that they all lie close to the corresponding meson-meson thresholds.

After identifying the scattering states, the other states are genuine tetraquarks. They all lie far above their \( S \)-wave decay channel(s). In particular, the \( q\bar{b}\bar{b} \) tetraquarks lie above all possible thresholds of two \( S \)-wave mesons. Thus they may be broad states. We also study their decay properties, which can be found in Tables XXXVI–XLVII.

### IV. CONCLUSIONS

Experimentally, lots of XYZ states have been found in this century. The singly charmed \( X(2900) \) and doubly charmed \( T_{cc} \) were also observed recently. For all these system, the exchange of a light meson may be important since they are composed at least two light (anti)quarks. It is difficult to determine whether they are loosely bound molecular states or compact tetraquark states. The recently discovered \( X(6900) \)'s are composed of four charm quarks. They are very likely compact tetraquarks since their interactions are mainly provided by gluon exchange. Similarly, if a triply heavy exotic state is observed in experiment, it is very likely a compact tetraquark.

In this work, we have systematically studied the triply heavy tetraquarks in an extended chromomagnetic model, which includes both colorelectric and chromomagnetic interactions. Our calculation suggests that the energy level is mainly determined by the color interaction. For the \( q\bar{c}\bar{c} \), \( q\bar{b}\bar{b} \) and \( q\bar{b}\bar{b} \) tetraquarks, the ground states are dominated by the \( 6_c \otimes 6_b \) component, which is similar to the fully heavy tetraquarks. However, the \( q\bar{c}\bar{b} \) tetraquarks are more like the doubly heavy tetraquarks, where the \( 6_c \otimes 6_b \) component is mostly in the higher mass states, and the ground states are dominated by \( 3_c \otimes 3_c \) components. We find no stable state which lie below the thresholds of two pseudoscalar mesons, in consistency with the results of Ref. [58]. The lowest axial-vector states with \( q\bar{b}\bar{b} \) flavor configuration might be narrow because they lie just above the thresholds of two pseudoscalar mesons, but they cannot decay into these channels because of the conservation of the angular momentum and parity.
FIG. 5. Mass spectra of the $ncc\bar{b}$ and $scc\bar{b}$ tetraquark states. The dotted lines indicate various meson-meson thresholds. The scattering states are marked with a dagger (†), along with the proportion of their dominant components. Here the predicted mass $M_{B_s^*} = 6338$ MeV of Godfrey et al. [78] is used. The masses are all in units of MeV.
FIG. 6. Mass spectra of the $nb\bar{c}$ and $sb\bar{b}$ tetraquark states. The dotted lines indicate various meson-meson thresholds. The scattering states are marked with a dagger ($^\dagger$), along with the proportion of their dominant components. Here the predicted mass $M_{D^*_c} = 6338$ MeV of Godfrey et al. [78] is used. The masses are all in units of MeV.
TABLE XXX. Masses and eigenvectors of the $ncc\bar{b}$ and $sc\bar{c}\bar{b}$ tetraquarks. The masses are all in units of MeV.

| System | $J^P$ | Mass  | Eigenvector          | Scattering state |
|--------|-------|-------|----------------------|------------------|
| $ncc\bar{b}$ | $0^+$ | 8123.2 | $\{0.864, 0.246, 0.273, 0.343\}$ | $\bar{D}B_c$ (89.7%) |

|        | 8561.0 | $\{-0.215, -0.524, 0.736, 0.370\}$ |                  |
| $1^+$  | 8287.8 | $\{0.789, -0.431, 0.240, 0.204, -0.152, 0.264\}$ | $\bar{D}_sB_c^*$ (87.0%) |
|        | 8368.4 | $\{-0.545, -0.397, 0.623, -0.013, -0.309, 0.249\}$ | $\bar{D}_s^*B_c$ (80.5%) |
|        | 8407.5 | $\{-0.168, -0.727, -0.622, -0.220, 0.049, 0.079\}$ |                  |
|        | 8498.8 | $\{0.006, 0.183, 0.043, -0.339, 0.487, 0.783\}$ |                  |
|        | 8531.2 | $\{0.227, 0.033, 0.164, -0.890, -0.266, -0.239\}$ |                  |
|        | 8551.1 | $\{-0.023, 0.307, -0.373, 0.045, -0.756, 0.439\}$ |                  |
| $2^+$  | 8434.2 | $\{0.966, 0.259\}$ | $\bar{D}_s^*B_c^*$ (88.0%) |
|        | 8566.3 | $\{-0.259, 0.966\}$ |                  |

With the obtained wave functions, we also calculate the partial decay rates of the tetraquarks. We hope that our studies can be of help for the future experimental searches.
