Bifurcations of solitary waves are classified for the generalized nonlinear Schrödinger equations with arbitrary nonlinearities and external potentials in arbitrary spatial dimensions. Analytical conditions are derived for three major types of solitary wave bifurcations, namely, saddle-node, pitchfork, and transcritical bifurcations. Shapes of power diagrams near these bifurcations are also obtained. It is shown that for pitchfork and transcritical bifurcations, their power diagrams look differently from their familiar solution-bifurcation diagrams. Numerical examples for these three types of bifurcations are given as well. Of these numerical examples, one shows a transcritical bifurcation, which is the first report of transcritical bifurcations in the generalized nonlinear Schrödinger equations. Another shows a power loop phenomenon which contains several saddle-node bifurcations, and a third example shows double pitchfork bifurcations. These numerical examples are in good agreement with the analytical results.

1. Introduction

Solitary waves are spatially localized and temporally stationary (or steadily moving) solutions of nonlinear wave equations. Solitary waves play an important role in the understanding of nonlinear wave dynamics and thus have been heavily studied for a wide range of nonlinear wave models arising in diverse physical disciplines [1, 2]. When the propagation constant of solitary waves
or physical parameters in the nonlinear wave equations changes, bifurcations
of solitary waves can occur. Indeed, various solitary wave bifurcations in
miscellaneous nonlinear wave models have been reported. Examples include
saddle-node bifurcations (also called fold bifurcations) [2–11], pitchfork
bifurcations (sometimes called symmetry-breaking bifurcations) [11–19],
transcritical bifurcations [7], and so on. Most of these reports on bifurcations are
numerical. In the few analytical studies, focus was on the quantitative prediction
of symmetry-breaking bifurcation points in the nonlinear Schrödinger (NLS)
equations with symmetric double-well potentials [13, 15, 16, 18, 19] and the
prediction of saddle-node and pitchfork bifurcation points in the NLS equations
with periodic potentials [11]. A general treatment of these bifurcations and
general analytical conditions for their occurrences are still lacking at this time.

In this paper, we systematically classify solitary wave bifurcations in the
generalized NLS equations with arbitrary nonlinearities and external potentials
in arbitrary spatial dimensions. These generalized NLS equations include the
Gross–Pitaevskii equations in Bose–Einstein condensates [20] and nonlinear
light-transmission equations in refractive-index-modulated optical media [1, 2]
as special cases. For this large class of wave equations, we derive sufficient
analytical conditions for three major types of solitary wave bifurcations,
namely, saddle-node, pitchfork, and transcritical bifurcations. In addition,
shapes of power diagrams near these bifurcation points are also derived. We will
show that the power diagram near a saddle-node bifurcation is a horizontally
oriented parabola; the power diagram near a pitchfork bifurcation is an extra
power curve bifurcating out from a smooth power curve on one side of the
bifurcation point (like a slanted letter “y”); and the power diagram near a
transcritical bifurcation comprises two smooth curves tangentially connected at
the bifurcation point. These analytical results are followed by various numerical
examples. One example shows a transcritical bifurcation, which is the first
report of transcritical bifurcations in the generalized NLS equations to the
author’s best knowledge. Another example shows double pitchfork bifurcations
combined with saddle-node bifurcations, and a third example shows a power
loop phenomenon which contains a number of saddle-node bifurcations. These
numerical examples of bifurcations are found to be in good agreement with
our analytical results.

2. Preliminaries

We consider the generalized nonlinear Schrödinger (GNLS) equations with
arbitrary forms of nonlinearity and external potentials in any spatial dimensions.
These equations can be written as

\[ iU_t + \nabla^2 U + F(|U|^2, x)U = 0, \]  (1)
where \( \nabla^2 = \partial^2/\partial x_1^2 + \partial^2/\partial x_2^2 + \cdots + \partial^2/\partial x_N^2 \) is the Laplacian in the \( N \)-dimensional space \( \mathbf{x} = (x_1, x_2, \ldots, x_N) \), and \( F(\cdot, \cdot) \) is a general real-valued function which includes nonlinearity as well as external potentials. These GNLS equations are physically important because they include the Gross–Pitaevskii equations in Bose–Einstein condensates [20] and nonlinear light-transmission equations in refractive-index-modulated optical media [1, 2] as special cases. Note that these GNLS equations are conservative and Hamiltonian.

For a large class of nonlinearities and potentials, these GNLS equations admit stationary solitary waves

\[
U(\mathbf{x}, t) = e^{i\mu t}u(\mathbf{x}),
\]

where \( u(\mathbf{x}) \) is a real localized function in the square-integrable functional space which satisfies the equation

\[
\nabla^2 u - \mu u + F(u^2, \mathbf{x})u = 0,
\]

and \( \mu \) is a real-valued propagation constant. Examples of such solitary waves can be found in numerous books and articles (see [1, 2] for instance). In these solitary waves, \( \mu \) is a free parameter, and \( u(\mathbf{x}) \) depends continuously on \( \mu \). Under certain conditions, these solitary waves undergo bifurcations at special values of \( \mu \). Reported examples of bifurcations in Equation (3) include saddle-node [2, 8, 9, 11] and pitchfork bifurcations [11, 13–19]. Transcritical bifurcations in this equation have not been reported yet (even though they have been found in other nonlinear wave models [7]).

For later analysis, we introduce the linearization operator of Equation (3),

\[
L_1 = \nabla^2 - \mu + \partial_u[F(u^2, \mathbf{x})u],
\]

which is a self-adjoint linear Schrödinger operator. We also introduce the standard inner product of functions,

\[
\langle f, g \rangle = \int_{-\infty}^{\infty} f^*(\mathbf{x})g(\mathbf{x})d\mathbf{x}.
\]

In addition, we define the power of a solitary wave \( u(\mathbf{x}; \mu) \) as

\[
P(\mu) = \langle u, u \rangle = \int_{-\infty}^{\infty} u^2(\mathbf{x}; \mu)d\mathbf{x}.
\]

This power function not only conveniently characterizes solitary wave families, but also plays an important role in the stability of these waves [2].

Our analysis of bifurcations starts with the basic observation that, if a bifurcation occurs at \( \mu = \mu_0 \), by denoting the corresponding solitary wave and the linearization operator as

\[
u_0(\mathbf{x}) = u(\mathbf{x}; \mu_0), \quad L_{10} = L_1|_{\mu=\mu_0, \ u=u_0},
\]

where
then the linear operator $L_{10}$ should have a discrete zero eigenvalue. This is a
necessary condition for bifurcations, hence it can be used to determine where
a bifurcation might occur. This condition is not sufficient though. Indeed, if
the function $F(|U|^2, x)$ in (1) does not depend explicitly on a certain spatial
dimension $x_j$, i.e., the GNLS equation (1) is translation-invariant along the
$x_j$-dimension, then for any solitary wave $u(x; \mu)$, $L_1 u_{x_j} = 0$, i.e., $L_1$ has a
discrete zero eigenvalue. But this zero eigenvalue of $L_1$ only corresponds to a
spatial translation of $u(x; \mu)$ and does not imply solitary wave bifurcations.
More will be said on this issue in the later text (see Remark 3 in Section 3).

In the next section, we will derive sufficient conditions for three major types
of solitary wave bifurcations. To simplify the analysis, we will focus on the
case where this zero eigenvalue of $L_{10}$ is simple. Hence, we introduce the
following assumption.

**Assumption 1.** Suppose at a certain propagation constant $\mu = \mu_0$, $L_{10}$
has a zero eigenvalue. Then it is assumed that this zero eigenvalue of $L_{10}$ is
simple and discrete.

This assumption is satisfied for almost all one-dimensional bifurcations and
many higher dimensional bifurcations. The case of $L_{10}$’s zero eigenvalue being
multifold (repeated) can be similarly treated, and that will be done elsewhere.

**Remark 1.** Because of Assumption 1, the zero eigenvalue of $L_{10}$ is simple
and discrete, thus this zero eigenvalue is not embedded inside the continuous
spectrum of $L_{10}$. This means that the solitary wave $u_0(x)$ at $\mu = \mu_0$ is not
an embedded soliton [2]. This fact allows us to construct solitary waves in
the vicinity of $\mu = \mu_0$ by perturbation series expansions without worrying
about continuous-wave tails beyond all orders of the perturbation expansion
[2, 21–23].

Under Assumption 1, we denote the single discrete (localized) eigenfunction
of $L_{10}$ at the zero eigenvalue as $\psi(x)$, i.e.,

$$L_{10} \psi = 0. \quad (8)$$

Because $L_{10}$ is a real operator, the eigenfunction $\psi$ can be normalized to be a
real function. Thus, $\psi$ will be taken as a real function in the remainder of this
article. We also denote

$$G(u; x) = F(u^2; x)u, \quad G_k(x) = \partial^k_u G|_{u=u_0}, \quad k = 0, 1, 2, 3, \ldots. \quad (9)$$

These notations will be used in the next sections.
3. The main results

In this section, we present sufficient analytical conditions for three major types of solitary wave bifurcations, namely, the saddle-node bifurcation, the pitchfork bifurcation, and the transcritical bifurcation. In addition, power diagrams of these solitary waves near bifurcation points will also be described.

First, we explain what these three bifurcations are. A saddle-node bifurcation is where on one side of the bifurcation point $\mu_0$, there are no solitary wave solutions; but on the other side of $\mu_0$, there are two distinct solitary wave branches. These two branches merge with each other as $\mu \to \mu_0$. This bifurcation is also called a fold bifurcation in the literature (following a similar practice in dynamical systems [24]). Examples of this bifurcation in the GNLS equation (3) can be found in [2, 8, 9, 11]. A pitchfork bifurcation is where on one side of the bifurcation point $\mu_0$, there is a single solitary wave branch; but on the other side of $\mu_0$, there are three distinct solitary wave branches. One of these three branches is a smooth continuation of the single-solution branch from the other side of $\mu_0$, but the other two branches are new and they bifurcate out at the bifurcation point $\mu_0$. As $\mu \to \mu_0$, these two new solution branches merge with the smooth branch. Examples of pitchfork bifurcations reported so far are all symmetry-breaking bifurcations [11, 13–19], where a smooth branch of symmetric or antisymmetric solitary waves exists on both sides of the bifurcation point, but two new branches of asymmetric solutions appear on only one side of the bifurcation point. A transcritical bifurcation is where there are two smooth branches of solitary waves which exist on both sides of the bifurcation point $\mu_0$, and these solutions on both branches approach each other as $\mu \to \mu_0$. So far, no examples of transcritical bifurcations of solitary waves have been reported in the GNLS equation (3) yet (to the author’s best knowledge). But these transcritical bifurcations do exist in Equation (3), and one such example will be presented in Section 5 of this article.

The main result of this article is the following theorem which gives sufficient analytical conditions for the above three major types of solitary wave bifurcations.

**Theorem 1.** Under Assumption 1, the following three statements hold.

1. If $\langle u_0, \psi \rangle \neq 0$ and $\langle G_2, \psi^3 \rangle \neq 0$, then a saddle-node bifurcation occurs at $\mu = \mu_0$. When these two nonzero quantities have the same (opposite) sign, the solutions bifurcate to the right (left) side of $\mu = \mu_0$.

2. If $\langle u_0, \psi \rangle = \langle G_2, \psi^3 \rangle = 0$, $\langle 1 - G_2 L_{10}^{-1} u_0, \psi^2 \rangle \neq 0$, and $\langle G_3, \psi^4 \rangle - 3\langle G_2 \psi^2, L_{10}^{-1} (G_2 \psi^2) \rangle \neq 0$, then a pitchfork bifurcation occurs at $\mu = \mu_0$. When these two nonzero quantities have the same (opposite) sign, the new solution branches bifurcate to the right (left) side of $\mu = \mu_0$. 

3. If \(\langle u_0, \psi \rangle = 0, \langle G_2, \psi^3 \rangle \neq 0\), and
\[
(1 - G_2 L_{10}^{-1} u_0, \psi^2)^2 > \langle G_2, \psi^3 \rangle \langle G_2 (L_{10}^{-1} u_0)^2 - 2 L_{10}^{-1} u_0, \psi \rangle,
\]
then a transcritical bifurcation occurs at \(\mu = \mu_0\).

It is noted that under the conditions of Cases 2 and 3 in this theorem, real quantities \(L_{10}^{-1} u_0\) and \(L_{10}^{-1} (G_2 \psi^2)\), which appear in these conditions, exist (see Lemma 1 in the next section).

Theorem 1 shows that in the generic case of \(\langle u_0, \psi \rangle \neq 0\) and \(\langle G_2, \psi^3 \rangle \neq 0\), a saddle-node bifurcation occurs. Pitchfork and transcritical bifurcations would arise only in more restrictive situations. For instance, pitchfork bifurcations generally occur only in symmetric potentials, see [11, 13–19] and Remark 2 below. Transcritical bifurcations are more rare, which explains why they have not been found in Equation (3) before. The above situation closely resembles that in finite-dimensional dynamical systems [25]. More will be said on this in the end of Section 5.

Remark 2. An important (dominant) class of pitchfork bifurcations is the symmetry-breaking bifurcation. Suppose, the potential in Equation (1) is symmetric, i.e.,
\[
F(u^2; -x) = F(u^2; x).
\]
In addition, suppose the solitary wave \(u_0(x)\) has certain symmetry (even or odd in \(x\)), and the eigenfunction \(\psi(x)\) has the opposite symmetry of \(u_0(x)\) (odd or even), i.e.,
\[
u_0(-x) = \pm u_0(x), \quad \psi(-x) = \mp \psi(x).
\]
From the notation (9), we see that
\[
G_2 = \left[ 6u \partial_{u^2} F(u^2; x) + 4u^3 \partial_{u^2} \partial_{u^2} F(u^2; x) \right]_{u=u_0},
\]
which has the same symmetry as \(u_0(x)\). Then obviously,
\[
\langle u_0, \psi \rangle = \langle G_2, \psi^3 \rangle = 0,
\]
thus the conditions of Case 2 in Theorem 1 are generically satisfied. Consequently, a pitchfork bifurcation occurs at \(\mu = \mu_0\). In this case, the two bifurcated solutions \(u^\pm(x; \mu)\) are simply related as
\[
u^-(x; \mu) = u^+(x; \mu).
\]
In addition, these bifurcated solutions break the symmetry of the original \(u_0(x)\) solution and are asymmetric, as can be seen from their asymptotic solution formulae in Equation (66) later. This explains why this pitchfork bifurcation is often called symmetry-breaking bifurcation in the literature. To the author’s knowledge, all pitchfork bifurcations reported so far are symmetry-breaking bifurcations.
Remark 3. Suppose Equation (1) is translation invariant along a certain spatial dimension $x_j$, i.e., $F(|U|^2, x)$ in (1) does not depend explicitly on $x_j$. If this equation admits a solitary wave $u_0(x)$ at $\mu = \mu_0$, then by differentiating Equation (3) with respect to $x_j$, we find that $L_{10}u_{0,x_j} = 0$, thus zero is a discrete eigenvalue of $L_{10}$ with eigenfunction $\psi = u_{0,x_j}$. In this case, simple calculations show that
\[
\langle u_0, \psi \rangle = (G_2, \psi^3) = (1 - G_2L_{10}^{-1}u_0, \psi^2) = 0,
\]
and
\[
(G_3, \psi^4) - 3(G_2\psi^2, L_{10}^{-1}(G_2\psi^2)) = 0.
\]
Thus, this case does not fall into any of the three cases in Theorem 1, hence no solitary wave bifurcation can be predicted. This is not surprising, because a zero eigenvalue induced by translation invariance does not create solitary wave bifurcations in general.

Power diagrams are important not only for displaying solitary wave bifurcations but also for predicting stability properties of these solitary waves [2]. The power diagrams near these three types of bifurcations are given in the following theorem.

Theorem 2. Suppose Assumption 1 holds. Denoting the power of the solitary wave at the bifurcation point as $P_0 = \langle u_0, u_0 \rangle$, then

1. near the saddle-node bifurcation in Case 1 of Theorem 1, power functions of the two solution branches $u^\pm(x; \mu)$ are
\[
P^\pm(\mu) = P_0 \pm P_1 \cdot (\mu - \mu_0)^{1/2} + O(\mu - \mu_0),
\]
where the constant $P_1$ is given by
\[
P_1 = 2\langle u_0, \psi \rangle \frac{2\langle u_0, \psi \rangle}{\langle G_2, \psi^3 \rangle};
\]

2. near the pitchfork bifurcation in Case 2 of Theorem 1, the power function for the smooth solution branch $u^0(x; \mu)$ is
\[
P^0(\mu) = P_0 + P_1^0 \cdot (\mu - \mu_0) + O((\mu - \mu_0)^3),
\]
where the constant $P_1^0$ is given by
\[
P_1^0 = 2\langle u_0, L_{10}^{-1}u_0 \rangle;
\]

power functions for the two bifurcated solution branches $u^\pm(x; \mu)$ are
\[
P^\pm(\mu) = P_0 + P_1 \cdot (\mu - \mu_0) + O((\mu - \mu_0)^{3/2}),
\]
where the constant $P_1$ is given by

$$P_1 = 2 \langle u_0, L_{10}^{-1} u_0 \rangle + \frac{6 (1 - G_2 L_{10}^{-1} u_0, \psi^2)^2}{\langle G_3, \psi^4 \rangle - 3 (G_2 \psi^2, L_{10}^{-1} (G_2 \psi^2))}; \quad (18)$$

3. near the transcritical bifurcation in Case 3 of Theorem 1, power functions for the two solution branches are

$$P^\pm(\mu) = P_0 + P_1 \cdot (\mu - \mu_0) + P_2^\pm \cdot (\mu - \mu_0)^2 + O((\mu - \mu_0)^3), \quad (19)$$

where the constants $P_1$ and $P_2^\pm$ are given by

$$P_1 = 2 \langle u_0, L_{10}^{-1} u_0 \rangle, \quad P_2^\pm = 2 \langle u_0, \hat{u}_2^\pm \rangle + \langle u_1^\pm, u_1^\pm \rangle, \quad (20)$$

with $u_1^\pm$ specified in Equation (78), $\hat{u}_2^\pm$ being particular solutions to Equation (79), and $b_1$ in (78) and (79) given in (81).

This theorem shows that the power diagram near a saddle-node bifurcation is a horizontally oriented parabola. Near a pitchfork bifurcation, power curves of the three solution branches are all linear functions of $\mu$. In addition, the two bifurcated solution branches $u^\pm(x; \mu)$ have the same power slope at the bifurcation point. In fact, in the dominant case of symmetry-breaking bifurcations discussed in Remark 2, power curves $P^\pm(\mu)$ of the two solution branches $u^\pm(x; \mu)$ are identical for all $\mu$ both near and not near the bifurcation point, i.e., $P^+(\mu) \equiv P^-(\mu)$, because of the relation (12). It is also important to note that the smooth solution branch $u^0(x; \mu)$ and the bifurcated solution branches $u^\pm(x; \mu)$ have different power slopes at the bifurcation point, i.e., $P^0_1 \neq P_1$, because the numerator in the second term of Equation (18) is nonzero for pitchfork bifurcations (see Theorem 1). Thus, the power diagram near a pitchfork bifurcation looks like a slanted letter “y.” Near a transcritical bifurcation, power slopes of the two solution branches at the bifurcation point are the same, but their curvatures are different in the generic case. Thus the power diagram near a transcritical bifurcation comprises two smooth curves tangentially connected at the bifurcation point. These features of the power diagrams (for pitchfork and transcritical bifurcations) differ significantly from their familiar solution-bifurcation diagrams, and these differences are illustrated schematically in Figure 1.

The upper row of this figure plots the deviation values $u(x_0; \mu) - u_0(x_0)$, as a function of $\mu$, between solitary waves $u(x; \mu)$ away from the bifurcation point and the solitary wave $u_0(x)$ at the bifurcation point at a representative (fixed) $x_0$ position. These curves are drawn using the leading-order perturbation series solutions (32) (for the saddle-node bifurcation), (43) and (66) (for the pitchfork bifurcation), and (88) (for the transcritical bifurcation), which we will derive in the next section. Note that these deviation diagrams closely resemble the corresponding bifurcation diagrams (of the same names) in finite-dimensional dynamical systems [25]. The lower row of Figure 1 plots
the associated power diagrams for the bifurcations in the upper row. These power curves are drawn using the power function’s asymptotic formulae (13), (15), (17), and (19) in Theorem 2. Notice that the power diagram of the pitchfork bifurcation has a double-branching structure rather than the familiar triple-branching structure, and the power diagram of the transcritical bifurcation has a tangential-intersection structure rather than the familiar “x”-like crossing structure. These power-diagram behaviors have no counterparts in finite-dimensional dynamical systems, and they should be borne in mind when identifying solitary wave bifurcations in the GNLS equations (1).

4. Proofs of the main results

To prove the main results in Theorems 1 and 2, the following lemma will be used.

Lemma 1. Suppose \( f(x) \) is a localized function. Then under Assumption 1, the linear inhomogeneous equation

\[
L_{10} \phi = f
\]
admits localized solutions $\phi$ if and only if the inhomogeneous term $f$ is orthogonal to the homogeneous solution $\psi$, i.e.,

$$\langle \psi, f \rangle = 0.$$  \hspace{1cm} (22)

This lemma is a direct consequence of the Fredholm Alternative Theorem. It can also be proved by expanding the localized function $f(x)$ and the solution $\phi(x)$ into the complete set of eigenfunctions of the Schrödinger operator $L_{10}$ and then solving for $\phi(x)$ directly.

In the later text, the orthogonality condition (22) will be called the solvability condition of the inhomogeneous equation (21) (for the existence of localized solutions).

Proof of Theorem 1. We will use the constructive method to prove this theorem. Specifically, we will explicitly construct solitary wave solutions, in the form of perturbation series expansions, which exist near $\mu = \mu_0$ under the conditions of this theorem. It will be shown that these perturbation series solutions can be constructed to all orders. The existence of available solitary wave solutions near $\mu = \mu_0$ will readily reveal the type of bifurcations at $\mu = \mu_0$.

Case 1: Saddle-node bifurcations

Here we consider the first case of Theorem 1, and show that under its conditions $\langle u_0, \psi \rangle \neq 0$ and $\langle G_2, \psi^3 \rangle \neq 0$, there exist two solitary wave branches on only one side of $\mu = \mu_0$, which merge with each other as $\mu \to \mu_0$. We will also show that no other solitary wave solutions can be found near $\mu = \mu_0$. Hence, a saddle-node bifurcation occurs here.

The solitary waves which exist near $\mu = \mu_0$ in this case have the following perturbation series expansions

$$u(x; \mu) = \sum_{k=0}^{\infty} (\mu - \mu_0)^{k/2} u_k(x)$$

$$= u_0(x) + (\mu - \mu_0)^{1/2} u_1(x) + (\mu - \mu_0) u_2(x) + \cdots.$$ \hspace{1cm} (23)

Inserting this expansion into Equation (3) and recalling the notations (9), we get the following sequence of equations for $u_k$ at order $(\mu - \mu_0)^{k/2}$, $k = 0, 1, 2, 3, \ldots$:

$$\nabla^2 u_0 - \mu_0 u_0 + F(u_0^2, x) u_0 = 0,$$ \hspace{1cm} (24)

$$L_{10} u_1 = 0,$$ \hspace{1cm} (25)

$$L_{10} u_2 = u_0 - \frac{1}{2!} G_2 u_1^2.$$ \hspace{1cm} (26)
\[ L_{10}u_3 = u_1 - G_2u_1u_2 - \frac{1}{3!}G_3u_1^3, \]  
\[ (27) \]

\[ L_{10}u_4 = u_2 - \frac{1}{2!}G_2(u_2^2 + 2u_1u_3) - \frac{1}{2!}G_3u_1^2u_2 - \frac{1}{4!}G_4u_1^4, \]
\[ \ldots \]
\[ (28) \]

The Equation (24) for \( u_0 \) is satisfied automatically because \( u_0 \) is a solitary wave of Equation (3) at \( \mu = \mu_0 \). The \( u_1 \) solution to Equation (25), under Assumption 1, is

\[ u_1 = b_1 \psi, \]  
\[ (29) \]

where \( b_1 \) is a constant. The \( u_2 \) function satisfies the linear inhomogeneous Equation (26). Because of Lemma 1, Equation (26) admits a localized solution for \( u_2 \) if and only if

\[ \left\langle \psi, u_0 - \frac{1}{2}G_2u_1^2 \right\rangle = 0. \]  
\[ (30) \]

Inserting the \( u_1 \) solution (29) into this orthogonality condition and recalling the assumptions of Case 1, we find that

\[ b_1 = \pm \eta, \quad \eta \equiv \sqrt{\frac{2\langle u_0, \psi \rangle}{\langle G_2, \psi^3 \rangle}}. \]  
\[ (31) \]

Thus, we get two \( b_1 \) solutions \( \pm \eta \) which are opposite of each other. Inserting the corresponding \( u_1 \) solutions (29) into (23), we then get two perturbation series solutions of \( u(x; \mu) \) as

\[ u^\pm(x; \mu) = u_0(x) \pm \eta(\mu - \mu_0)^{1/2}\psi(x) + O(\mu - \mu_0). \]  
\[ (32) \]

If \( \langle u_0, \psi \rangle \) and \( \langle G_2, \psi^3 \rangle \) have the same sign, then \( \eta \) is real. Recalling that \( u_0(x) \) and \( \psi(x) \) are both real localized functions, we see that these two perturbation series solutions (32) give two real-valued (legitimate) solitary waves when \( \mu > \mu_0 \), but not when \( \mu < \mu_0 \). On the other hand, if \( \langle u_0, \psi \rangle \) and \( \langle G_2, \psi^3 \rangle \) have the opposite sign, \( \eta \) is purely imaginary. In this case, the perturbation series solutions (32) give two real-valued solitary waves when \( \mu < \mu_0 \), but not when \( \mu > \mu_0 \).

Next we show that the two real localized perturbation series solutions (32), which exist on only one side of \( \mu = \mu_0 \), can be constructed to all orders of \( (\mu - \mu_0)^{1/2} \). Let us first consider the \( u_2 \) Equation (26). When \( b_1 \) is selected from Equation (31), the orthogonality condition (30) is satisfied. Thus by Lemma 1, localized solutions for \( u_2 \) exist. Because the inhomogeneous term and the linear operator \( L_{10} \) of (26) are both real, these localized \( u_2 \) solutions can also be
made real. Let us denote one of such real localized \( u_2 \) solutions as \( \hat{u}_2 \), i.e.,

\[
\hat{u}_2 = L_{10}^{-1} \left( u_0 - \frac{1}{2} \eta^2 G_2 \psi^2 \right),
\]

then because \( \psi \) is a homogeneous localized solution of (26), the general localized solution of (26) is

\[
u_2 = \hat{u}_2 + b_2 \psi,
\]

where \( b_2 \) is a constant to be determined.

Now we proceed to the \( u_3 \) Equation (27). Inserting the \( u_1 \) and \( u_2 \) solutions (29) and (33) into (27), we get

\[
L_{10} u_3 = b_1 \left( \psi - G_2 \hat{u}_2 \psi - \frac{1}{3!} b_1^2 G_3 \psi^3 - b_2 G_2 \psi^2 \right).
\]

By Lemma 1, this equation admits localized \( u_3 \) solutions if and only if its right hand side is orthogonal to the homogeneous solution \( \psi \). Imposition of this orthogonality condition yields the \( b_2 \) value as

\[
b_2 = \frac{\langle 1 - G_2 \hat{u}_2 - \eta^2 G_3 \psi^2 / 3!, \psi^2 \rangle}{\langle G_2, \psi^3 \rangle},
\]

which is a real constant. Note that with this \( b_2 \) value, the solution \( u_2(x) \) in (33) is the same for both choices \( \pm \eta \) of \( b_1 \) in the \( u_1 \) solution (29), thus \( u_2(x) \) is the same for both branches of the perturbation series solutions \( u^\pm(x; \mu) \) in (32).

With the \( b_2 \) value (35), Equation (34) admits localized solutions

\[
u_3 = b_1 (\hat{u}_3 + b_3 \psi),
\]

where \( \hat{u}_3 \) is a real-valued localized solution of Equation (34) but without the \( b_1 \) factor on its right hand side, and \( b_3 \) is a constant. This \( b_3 \) will be determined from the solvability (orthogonality) condition of the \( u_4 \) Equation (28) and can be found to be real. Note that \( \hat{u}_3(x) \) and \( b_3 \) are also the same for both branches of perturbation series solutions \( u^\pm(x; \mu) \).

Proceeding to higher orders and using the method of induction, we can readily show that all even terms \( u_{2n} \) are of the form

\[
u_{2n} = \hat{u}_{2n} + b_{2n} \psi, \quad n = 1, 2, \ldots,
\]

and all odd terms are of the form

\[
u_{2n+1} = b_1 [\hat{u}_{2n+1} + b_{2n+1} \psi], \quad n = 1, 2, \ldots,
\]

where \( \hat{u}_{2n}(x) \) and \( \hat{u}_{2n+1}(x) \) are certain real localized functions, and \( b_{2n}, b_{2n+1} \) are certain unique real constants. In addition, \( u_{2n}(x), \hat{u}_{2n+1}(x) \), and \( b_{2n+1} \) are the same for both branches of perturbation series solutions \( u^\pm(x; \mu) \). Thus, by denoting \( \tilde{u}_{2n+1} = \hat{u}_{2n+1} + b_{2n+1} \psi \), we have

\[
u_{2n} = u_{2n}(x), \quad u_{2n+1}^\pm = \pm \eta \tilde{u}_{2n+1}(x).
\]
Inserting these $u_{2n}^\pm$ and $u_{2n+1}^\pm$ solutions into (23), we obtain two perturbation series solutions for $u(x; \mu)$, to all orders of $(\mu - \mu_0)^{1/2}$, as

$$u^\pm(x; \mu) = u_0(x) + \sum_{n=1}^\infty (\mu - \mu_0)^n u_{2n}(x)$$

$$\pm \eta (\mu - \mu_0)^{1/2} \left\{ \psi(x) + \sum_{n=1}^\infty (\mu - \mu_0)^n \tilde{u}_{2n+1}(x) \right\}. \quad (40)$$

These two solutions exist on only one side of $\mu = \mu_0$ and are real and localized. The side of their existence depends on whether $\eta$ in (31) is real or imaginary. When $\mu \to \mu_0$, $u^\pm(x; \mu) \to u_0(x)$, thus $u^\pm(x; \mu)$ approach each other and merge at the bifurcation point.

Finally, we show that except the above two solitary wave branches which exist on only one side of the bifurcation point, we can not find other solitary wave solutions near this bifurcation point. For instance, if we look for smooth solitary wave branches which exist on both sides of $\mu = \mu_0$, then their perturbation expansions should be

$$u(x; \mu) = u_0(x) + (\mu - \mu_0)u_1(x) + (\mu - \mu_0)^2 u_2(x) + \cdots. \quad (41)$$

When this expansion is substituted into (3), the $O(1)$ equation is still (24) which is satisfied. At $O(\mu - \mu_0)$, we get the equation for $u_1$ as

$$L_{10} u_1 = u_0. \quad (42)$$

Under conditions of Case 1, $\langle \psi, u_0 \rangle \neq 0$. Thus by Lemma 1, Equation (42) can not admit any localized solution for $u_1$. This means that solitary waves with the perturbation expansion (41) can not exist in this case. We have also searched solitary waves near $\mu = \mu_0$ in other perturbation series expansions, and could not find such solutions either. Thus a saddle-node bifurcation occurs at $\mu = \mu_0$.

**Case 2: Pitchfork bifurcations**

Now we consider the second case of Theorem 1. We will show that under conditions of this case, a smooth branch of solitary waves exists on both sides of $\mu = \mu_0$. In addition, two other solitary wave branches exist on only one side of $\mu = \mu_0$. As $\mu \to \mu_0$, all these solution branches approach the same solitary wave $u_0(x)$. Thus a pitchfork bifurcation occurs at $\mu = \mu_0$.

(i) We first construct the smooth branch of solitary waves which exists on both sides of $\mu = \mu_0$. These solitary waves have the following perturbation series expansion

$$u^0(x; \mu) = \sum_{k=0}^\infty (\mu - \mu_0)^k u_k(x). \quad (43)$$
Inserting this expansion into Equation (3), we get the following sequence of equations for $u_k$ at orders $(\mu - \mu_0)^k, k = 0, 1, 2, 3, \ldots$:

\[
\nabla^2 u_0 - \mu_0 u_0 + F(u_0^2, x)u_0 = 0, \tag{44}
\]

\[
L_{10} u_1 = u_0, \tag{45}
\]

\[
L_{10} u_2 = u_1 - \frac{1}{2!} G_2 u_1^2, \tag{46}
\]

\[
L_{10} u_3 = u_2 - G_2 u_1 u_2 - \frac{1}{3!} G_3 u_1^3, \tag{47}
\]

\[
L_{10} u_4 = u_3 - \frac{1}{2!} G_2 (u_2^2 + 2u_1 u_3) - \frac{1}{2!} G_3 u_1^2 u_2 - \frac{1}{4!} G_4 u_1^4, \tag{48}
\]

The Equation (44) for $u_0$ is satisfied automatically. Under conditions of Case 2, $\langle \psi, u_0 \rangle = 0$. Thus by Lemma 1, the solvability condition for the $u_1$ Equation (45) is satisfied, hence this equation admits localized solutions

\[
u_1 = \hat{u}_1 + b_1 \psi, \tag{49}
\]

where

\[
\hat{u}_1 = L_{10}^{-1} u_0 \tag{50}
\]

is a real localized particular solution to Equation (45), and $b_1$ is a constant to be determined. Inserting this $u_1$ solution into the $u_2$ Equation (46), we get

\[
L_{10} u_2 = \hat{u}_1 - \frac{1}{2} G_2 \hat{u}_1^2 + b_1 \psi (1 - G_2 \hat{u}_1) - \frac{1}{2} b_1^2 G_2 \psi^2. \tag{51}
\]

By Lemma 1, the solvability condition of this $u_2$ equation is that its right hand side be orthogonal to the homogeneous solution $\psi$. Under conditions of Case 2, $\langle G_2, \psi \rangle = 0$. Thus this solvability condition gives

\[
b_1 \left(1 - G_2 L_{10}^{-1} u_0, \psi^2 \right) = \left\{ \frac{1}{2} G_2 \hat{u}_1^2 - \hat{u}_1, \psi \right\}. \tag{52}
\]

Because the inner product on the left side of this equation is nonzero under conditions of Case 2, this equation yields a unique $b_1$ value as

\[
b_1 = \frac{\langle G_2 \hat{u}_1^2 / 2 - \hat{u}_1, \psi \rangle}{\langle 1 - G_2 L_{10}^{-1} u_0, \psi^2 \rangle}, \tag{53}
\]

which is a real constant. Hence a real localized solution for $u_1$ has been obtained.

With the above $b_1$ value, the solvability condition of the $u_2$ Equation (51) is satisfied. Thus this equation admits a real localized particular solution $\hat{u}_2$, and
its general solution is
\[ u_2 = \hat{u}_2 + b_2 \psi, \tag{54} \]
where \( b_2 \) is another constant to be determined.

Inserting this \( u_2 \) solution into the \( u_3 \) Equation (47), this equation becomes
\[ L_{10} u_3 = b_2 \psi (1 - G_2 u_1) + \hat{u}_2 (1 - G_2 u_1) - \frac{1}{3!} G_3 u_1^3. \tag{55} \]
By Lemma 1, the solvability condition of this \( u_3 \) equation is that its right hand side be orthogonal to \( \psi \). Using the \( u_1 \) solution (49) and the conditions of Case 2, we see that
\[ \langle \psi (1 - G_2 u_1), \psi \rangle = \langle 1 - G_2 L_{10}^{-1} u_0, \psi^2 \rangle \neq 0. \tag{56} \]
Thus, the solvability condition of Equation (55) yields a unique real \( b_2 \) value,
\[ b_2 = -\frac{\langle \hat{u}_2 (1 - G_2 u_1) - G_3 u_1^3 / 3! \psi \rangle}{\langle \psi (1 - G_2 u_1), \psi \rangle}, \]
hence a real localized \( u_2 \) solution (54) is then obtained. At this \( b_2 \) value, Equation (55) admits a real localized particular solution \( \hat{u}_3 \), and its general solution is
\[ u_3 = \hat{u}_3 + b_3 \psi, \tag{57} \]
where \( b_3 \) is another constant to be determined.

Pursuing this calculation to higher orders, it is easy to see that for any \( n \geq 2 \), the \( u_n \) solution is of the form
\[ u_n = \hat{u}_n + b_n \psi, \tag{58} \]
where \( \hat{u}_n \) is a real localized particular solution of the \( u_n \) equation, and \( b_n \) is a constant to be determined from the solvability condition of the \( u_{n+1} \) equation. The \( u_{n+1} \) equation is always of the form
\[ L_{10} u_{n+1} = (1 - G_2 u_1) u_n + \mathcal{F}_{n+1}(u_0, u_1, \ldots, u_{n-1}; \mathbf{x}), \tag{59} \]
where \( \mathcal{F}_{n+1} \) is some real function which depends on the already obtained real localized solutions \( u_0, u_1, \ldots, u_{n-1} \) as well as \( \mathbf{x} \). Inserting the \( u_n \) solution (58) into (59) and using Equation (56), the solvability condition of (59) is met at a unique real \( b_n \) value, hence a real localized \( u_n \) solution (58) is obtained. Meanwhile, because the solvability condition of (59) is met, a real localized particular solution \( \hat{u}_{n+1} \) exists, and the general \( u_{n+1} \) solution is of the form (58) with the index \( n \) replaced by \( n + 1 \). This process then repeats itself. Hence, a real-valued and localized perturbation series solution (43) is constructed to all orders, and it gives a branch of real-valued solitary waves \( u^0(\mathbf{x}; \mu) \) which exists on both sides of \( \mu = \mu_0 \) and depends smoothly on \( \mu \).
(ii) Next we construct two additional solitary wave branches which exist on only one side of $\mu = \mu_0$ and merge with the above smooth solution branch at $\mu = \mu_0$. These additional solitary wave branches have the following perturbation series expansion

$$u(x; \mu) = \sum_{k=0}^{\infty} (\mu - \mu_0)^{k/2} u_k(x).$$

This perturbation series is of the same form as (23) in Case 1. Thus, when this perturbation series is substituted into Equation (3), the resulting equations for $u_k$ are the same as (24)–(28) before. But because the conditions for Case 2 are different from those for Case 1, solutions $u_k$ for the perturbation series here will differ from those in (23), as we will show below.

First, the Equation (24) for $u_0$ is satisfied automatically because $u_0$ is a solitary wave of (3) at $\mu = \mu_0$. The solution $u_1$ to Equation (25), under Assumption 1, is

$$u_1 = b_1 \psi,$$

where $b_1$ is a constant to be determined. Inserting this $u_1$ solution into the $u_2$ Equation (26), we get

$$L_{10}u_2 = u_0 - \frac{1}{2}b_1^2 G_2 \psi^2.$$

Because of conditions of Case 2, both $u_0$ and $G_2 \psi^2$ are orthogonal to $\psi$. Thus by Lemma 1, both $L_{10}^{-1}u_0$ and $L_{10}^{-1}(G_2 \psi^2)$ exist and are certain real localized functions. Hence, the solution $u_2$ to Equation (62) is

$$u_2 = L_{10}^{-1}u_0 - \frac{1}{2}b_1^2 L_{10}^{-1}(G_2 \psi^2) + b_2 \psi,$$

where $b_2$ is another constant to be determined. Inserting these $u_1$ and $u_2$ solutions into (27), the $u_3$ equation is

$$L_{10}u_3 = b_1 \left\{ (1 - G_2 L_{10}^{-1}u_0) \psi - \frac{1}{3!} b_1^2 \left[ G_3 \psi^3 - 3G_2 \psi L_{10}^{-1}(G_2 \psi^2) \right] - b_2 G_2 \psi^2 \right\}.$$

In view of the conditions of Case 2, the solvability condition of this $u_3$ equation yields the $b_1$ value as

$$b_1 = \pm \nu, \quad \nu \equiv \frac{6(1 - G_2 L_{10}^{-1}u_0, \psi^2)}{\langle G_3, \psi^4 \rangle - 3\langle G_2 \psi^2, L_{10}^{-1}(G_2 \psi^2) \rangle}.$$

Two $b_1$ values $\pm \nu$ are obtained which are opposite of each other. Inserting the corresponding $u_1$ solutions (61) into (60), we then get two solutions $u^\pm(x; \mu)$.
as perturbation series

\[ u^\pm(x; \mu) = u_0(x) \pm v(\mu - \mu_0)^{1/2} \psi(x) + O(\mu - \mu_0), \]  

(66)

where \( v \) is given in (65). If the numerator and denominator under the square root of (65) have the same sign, then \( v \) is real. In this case, two real localized perturbation series solutions (66) are obtained when \( \mu > \mu_0 \). If the numerator and denominator in (65) have the opposite sign, then \( v \) is purely imaginary. In this case, two real localized perturbation series solutions (66) are obtained when \( \mu < \mu_0 \).

Next, we show that the two real localized perturbation series solutions (66), which exist on only one side of \( \mu = \mu_0 \), can be constructed to all orders of \((\mu - \mu_0)^{1/2}\). With the choice of \( b_1 \) values in (65), the solvability condition of the \( u_3 \) Equation (64) is met, thus the \( u_3 \) solution is

\[ u_3 = b_1[\hat{u}_3 - b_2 L_{10}^{-1}(G_2 \psi^2) + b_3 \psi], \]  

(67)

where \( \hat{u}_3 \) is a real localized function which satisfies the equation

\[ L_{10}\hat{u}_3 = (1 - G_2 L_{10}^{-1}u_0) \psi - \frac{1}{3!}v^2[G_3 \psi^3 - 3G_2 \psi L_{10}^{-1}(G_2 \psi^2)], \]  

(68)

and \( b_3 \) is a constant to be determined. Inserting these \( u_1, u_2, \) and \( u_3 \) solutions into (28), the \( u_4 \) equation becomes

\[ L_{10}u_4 = b_2 \left\{ (1 - G_2 L_{10}^{-1}u_0) \psi - \frac{1}{2}b_1^2[G_3 \psi^3 - 3G_2 \psi L_{10}^{-1}(G_2 \psi^2)] \right\} \]

\[ - \frac{1}{2}b_2^2 G_2 \psi^2 + \mathcal{F}_4(u_0, \psi, b_2^2, x) - b_1^2 b_3 G_2 \psi^2, \]  

(69)

where \( \mathcal{F}_4 \) is a real localized function which depends on \( u_0, \psi, b_1^2 \), and other already obtained real functions (such as \( \hat{u}_3 \)). Using the \( b_1 \) formula (65) as well as conditions of Case 2, the solvability condition of this \( u_4 \) equation is met at the unique real \( b_2 \) value,

\[ b_2 = \frac{\langle \mathcal{F}_4, \psi \rangle}{2\langle 1 - G_2 L_{10}^{-1}u_0, \psi^2 \rangle}. \]  

(70)

When this \( b_2 \) value is inserted into (63), a real localized \( u_2 \) solution is then obtained. Note that this \( b_2 \) is the same for both choices \( \pm v \) of \( b_1 \) in the \( u_1 \) solution (61), thus \( u_2(x) \) is the same for both branches of the perturbation series solutions \( u^\pm(x; \mu) \) in (66).

For the \( b_2 \) value given in (70), the solvability condition of the \( u_4 \) Equation (69) is satisfied, thus this equation admits the following localized solution

\[ u_4 = \hat{u}_4 - v^2 b_3 L_{10}^{-1}(G_2 \psi^2) + b_4 \psi, \]  

(71)

where \( \hat{u}_4 \) is a real localized function which satisfies the \( u_4 \) Equation (69) but without the last \( (b_3) \) term, and \( b_4 \) is a new constant to be determined.
Starting from \( n \geq 5 \), the \( u_n \) equation can be derived from (3) and the expansion (60), and is of the form

\[
L_{10}u_{2n+1} = u_{2n-1} - G_2(u_1u_{2n} + u_2u_{2n-1}) - \frac{1}{2}G_3u^1_1u_{2n-1} + b_1\mathcal{H}_{2n+1}(u_0, \psi, b_1^2, x), \quad n \geq 2,
\]

(72)

\[
L_{10}u_{2n+2} = u_{2n} - G_2(u_1u_{2n+1} + u_2u_{2n}) - \frac{1}{2}G_3u^2_1u_{2n} + \mathcal{H}_{2n+2}(u_0, \psi, b_1^2, x), \quad n \geq 2,
\]

(73)

where \( \mathcal{H}_{2n+1} \) and \( \mathcal{H}_{2n+2} \) are real localized functions which depend on \( u_0, \psi, b_1^2 \), and other already fully determined real quantities (such as \( \hat{u}_3, \hat{u}_4, b_2 \), etc.). Using the method of induction as well as conditions of Case 2, we can show that all \( u_n \) solutions are of the form

\[
u_{2n+1} = b_1\left[\hat{u}_{2n+1} - b_{2n}L_{10}^{-1}(G_2\psi^2) + b_{2n+1}\psi\right], \quad n \geq 1,
\]

(74)

\[
u_{2n+2} = \hat{u}_{2n+2} - v^2b_{2n+1}L_{10}^{-1}(G_2\psi^2) + b_{2n+2}\psi, \quad n \geq 1,
\]

(75)

where \( \hat{u}_{2n+1} \) and \( \hat{u}_{2n+2} \) are certain real localized functions, and \( b_{2n+1} \) and \( b_{2n+2} \) are real constants which are determined uniquely from the solvability conditions of the \( u_{2n+3} \) and \( u_{2n+4} \) equations. We can also show that \( \hat{u}_{2n+1}, \hat{u}_{2n+2}, b_{2n+1}, \) and \( b_{2n+2} \) depend on \( b_1^2 \) as a whole and are thus the same for both solution branches \( u^\pm(x; \mu) \). Inserting these solutions into the perturbation series (60), we obtain two branches of solitary waves \( u^\pm(x; \mu) \) whose perturbation series expansions are

\[
u^\pm(x; \mu) = u_0(x) + \sum_{n=1}^{\infty}(\mu - \mu_0)^nu_{2n}(x)
\]

\[
\pm v(\mu - \mu_0)^{1/2}\left\{\psi(x) + \sum_{n=1}^{\infty}(\mu - \mu_0)^nu_{2n+1}(x)\right\},
\]

(76)

where real localized functions \( u_{2n} \) are given by (63) and (75), real localized functions \( \hat{u}_{2n+1} \) are as \( u_{2n+1} \) in (74) but without the \( b_1 \) factor, and \( v \) is given in (65). These two real solitary waves exist on the side of \( \mu > \mu_0 \) \( (\mu < \mu_0) \) when \( v \) is real (purely imaginary). When \( \mu \rightarrow \mu_0 \), they both approach \( u_0(x) \), thus these \( u^\pm(x; \mu) \) solution branches merge with the smooth \( u^0(x; \mu) \) solution branch in (43) at \( \mu = \mu_0 \).

The existence of the smooth solution branch \( u^0(x; \mu) \) in (43) on both sides of \( \mu = \mu_0 \) as well as two additional solution branches \( u^\pm(x; \mu) \) in (76) on only one side of \( \mu = \mu_0 \) indicates that a pitchfork bifurcation occurs at \( \mu = \mu_0 \).
Case 3: Transcritical bifurcations

Now we consider the third case of Theorem 1. We will show that under conditions of this case, two smooth branches of solitary waves exist on both sides of $\mu = \mu_0$, and these branches intersect at $\mu = \mu_0$ where solitary waves on the two branches become identical. Thus a transcritical bifurcation occurs at $\mu = \mu_0$.

In this third case, we seek solitary wave solutions which exist on both sides of $\mu = \mu_0$ and depend smoothly on $\mu$ near $\mu = \mu_0$. The perturbation series expansion of such solutions is

$$u(x; \mu) = \sum_{k=0}^{\infty} (\mu - \mu_0)^k u_k(x). \tag{77}$$

The form of this expansion is the same as (43) in Case 2, thus the equations for $u_k$ are also the same as (44)–(48) before. However, the solutions to these equations will differ from the previous ones in Case 2 because of different conditions of the present case.

The $u_0$ Equation (44) is satisfied automatically because $u_0$ is a solitary wave of Equation (3) at $\mu = \mu_0$. Under conditions of Case 3, the solvability condition of the $u_1$ Equation (45), $\langle u_0, \psi \rangle = 0$, is met. Thus by Lemma 1, localized $u_1$ solutions of the form

$$u_1 = L_{10}^{-1}u_0 + b_1 \psi \tag{78}$$

are admitted. Here $L_{10}^{-1}u_0$ is a real and localized particular solution to Equation (45), and $b_1$ is a constant to be determined. Inserting this $u_1$ solution into the $u_2$ Equation (46), this equation becomes

$$L_{10}u_2 = L_{10}^{-1}u_0 - \frac{1}{2} G_2(L_{10}^{-1}u_0)^2 + b_1 (1 - G_2 L_{10}^{-1}u_0) \psi - \frac{1}{2} b_1^2 G_2 \psi^2. \tag{79}$$

The solvability condition of this equation gives the following quadratic equation for $b_1$:

$$\langle G_2, \psi \rangle b_1^2 - 2 \langle 1 - G_2 L_{10}^{-1}u_0, \psi^2 \rangle b_1 + \langle G_2(L_{10}^{-1}u_0)^2 - 2L_{10}^{-1}u_0, \psi \rangle = 0. \tag{80}$$

Under conditions of Case 3, the coefficient of the $b_1^2$ term in this quadratic equation is nonzero, and

$$\Delta \equiv \langle 1 - G_2 L_{10}^{-1}u_0, \psi \rangle^2 - \langle G_2, \psi^3 \rangle \langle G_2(L_{10}^{-1}u_0)^2 - 2L_{10}^{-1}u_0, \psi \rangle > 0.$$

Thus, this quadratic equation admits the following two real roots

$$b_1 = b_1^\pm \equiv \frac{\langle 1 - G_2 L_{10}^{-1}u_0, \psi^2 \rangle \pm \sqrt{\Delta}}{\langle G_2, \psi^3 \rangle}. \tag{81}$$

For each of these two $b_1$ values, a real localized $u_1$ solution (78) is obtained. In addition, a real and localized particular solution $\hat{u}_2$ to the $u_2$ Equation (79)
exists, hence the \( u_2 \) solution is
\[
   u_2 = \hat{u}_2 + b_2 \psi, \tag{82}
\]
where \( b_2 \) is a new constant to be determined.

Inserting the above \( u_2 \) solution into the \( u_3 \) Equation (47), we get
\[
   L_{10} u_3 = b_2 (1 - G_2 u_1) \psi + (1 - G_2 u_1) \hat{u}_2 - \frac{1}{3!} G_3 u_1^3. \tag{83}
\]
Using the \( u_1 \) solution (78) and the \( b_1 \) formula (81), we find that
\[
   \langle (1 - G_2 u_1) \psi, \psi \rangle = \langle 1 - G_2 L_{10}^{-1} u_0, \psi \rangle - b_1 \langle G_2, \psi^3 \rangle = \mp \sqrt{\Delta} \neq 0. \tag{84}
\]
Thus the solvability condition of Equation (83) yields a real constant \( b_2 \) as
\[
   b_2 = -\frac{\langle (1 - G_2 u_1) \hat{u}_2 - G_3 u_1^3/3!, \psi \rangle}{\langle (1 - G_2 u_1) \psi, \psi \rangle}.
\]
For this \( b_2 \) value, the solvability condition of the \( u_3 \) Equation (83) is satisfied, thus this equation admits a real localized particular solution \( \hat{u}_3 \), and the general \( u_3 \) solution is
\[
   u_3 = \hat{u}_3 + b_3 \psi, \tag{85}
\]
where \( b_3 \) is another constant to be determined.

Pursuing this calculation to higher orders, it is easy to see that for any \( n \geq 2 \), the \( u_n \) solution is of the form
\[
   u_n = \hat{u}_n + b_n \psi, \tag{86}
\]
where \( \hat{u}_n \) is a real localized particular solution of the \( u_n \) equation, and \( b_n \) is a real constant to be determined from the solvability condition of the \( u_{n+1} \) equation. The \( u_{n+1} \) equation is always of the form
\[
   L_{10} u_{n+1} = (1 - G_2 u_1) u_n + F_{n+1}(u_0, u_1, \ldots, u_{n-1}; x), \tag{87}
\]
where \( F_{n+1} \) is some real function which depends on the already obtained real localized solutions \( u_0, u_1, \ldots, u_{n-1} \) and \( x \). Inserting the \( u_n \) solution (86) into (87) and in view of Equation (84), the solvability condition of (87) then yields a unique real value for the constant \( b_n \).

In the above solution process, because \( b_1 \) can take either one of the two real roots \( b_1^{\pm} \) in (81), \( u_1 \) in (78) then has two corresponding solutions \( u_1^{\pm} \). These two \( u_1 \) solutions cascade up to higher orders, and thus all \( u_n \) functions have two solutions \( u_n^{\pm} \). Consequently, two real-valued and localized perturbation series solutions
\[
   u^{\pm}(x; \mu) = u_0(x) + \sum_{k=1}^\infty (\mu - \mu_0)^k u_k^{\pm}(x) \tag{88}
\]
are obtained to all orders, and they provide two branches of real-valued solitary waves $u^\pm(x; \mu)$ which exist on both sides of $\mu = \mu_0$ and depend smoothly on $\mu$. When $\mu \rightarrow \mu_0$, both $u^\pm(x; \mu)$ approach $u_0(x)$, thus these two solution branches intersect at $\mu = \mu_0$. As a result, a transcritical bifurcation occurs at $\mu = \mu_0$. This completes the proof of Theorem 1.

Next, we prove Theorem 2 on power diagrams near bifurcation points.

**Proof of Theorem 2.** The power formula (13) of saddle-node bifurcations can be derived easily from the perturbation series solutions (23) and the $u_1$ solution (29) with $b_1$ given by Equation (31). The power formula (15) for the smooth solution branch $u_0^0(x; \mu)$ in a pitchfork bifurcation can be derived readily from the perturbation series solutions (43) and the $u_1$ solution (49). To derive the power formula (17) for the two bifurcated solution branches in a pitchfork bifurcation, we substitute the $u_1$, $u_2$ solutions in (61) and (63) into the expansion (76), and find that the power function is given by (17), where

$$P_1 = 2\langle u_0, L^{-1}_{10}u_0 \rangle + b_1^2\left[\langle \psi, \psi \rangle - \langle u_0, L^{-1}_{10}(G_2\psi^2) \rangle\right],$$

(89)

whose value is the same for both bifurcated branches. Because $L^{-1}_{10}$ is self-adjoint and $L^{-1}_{10}u_0$ exists (by Lemma 1), this $P_1$ coefficient can then be rewritten as (18) (here the $b_1$ formula (65) is also used). The power formula (19) for transcritical bifurcations can be derived easily from the perturbation series solutions (88) and the $u_1$, $u_2$ solutions (78), (82).

5. Numerical examples of solitary wave bifurcations

In this section, we present numerical examples for these three types of solitary wave bifurcations, and compare them with the analytical results presented in Theorems 1 and 2. So far, examples of saddle-node and pitchfork bifurcations of solitary waves have been reported in the GNLS equations (1) with various potentials and nonlinearities [2, 8, 9, 11, 13–19]. Here we will present some new examples of saddle-node and pitchfork bifurcations in the GNLS equations which exhibit interesting novel features. In addition, we will present the first example of transcritical bifurcation in these GNLS equations.

**Example 1. Combined saddle-node and double-pitchfork bifurcations.** The first example we choose is the one-dimensional GNLS equation (1) with a symmetric double-well potential and cubic-quintic nonlinearity:

$$iU_t + U_{xx} - V(x)U + |U|^2U - \gamma |U|^4U = 0,$$

(90)

where the symmetric double-well potential $V(x)$ is taken of the form

$$V(x) = -V_0\left[\text{sech}^2(x + x_0) + \text{sech}^2(x - x_0)\right],$$

(91)
$V_0 > 0$ is the potential depth, $2x_0$ is the separation between the two wells, and $\gamma > 0$ is the coefficient of the quintic nonlinearity. Note that the cubic and quintic nonlinear terms in (90) have the opposite sign, and the quintic term induces a self-defocusing effect which counters the self-focusing effect of the cubic term. One may also view this opposing cubic-quintic nonlinearity as a Taylor-series approximation to the saturable nonlinearity in photorefractive crystals [26]. The parameter values in the above GNLS model are chosen as

$$V_0 = 2.8, \quad x_0 = 1.5, \quad \gamma = 0.25.$$ (92)

Solitary waves in Equation (90) are sought of the form (2), where $u(x)$ is a real localized function satisfying the equation

$$u_{xx} - \mu u - V(x)u + u^3 - \gamma u^5 = 0.$$ (93)

When $u(x)$ is infinitesimal, the linear Schrödinger operator of Equation (93) admits a positive symmetric discrete eigenfunction at eigenvalue $\mu \approx 1.7896$. This eigenmode is the ground state of the underlying double-well potential. From this linear (infinitesimal) eigenmode, a family of positive symmetric solitary waves bifurcates out. The power curve of this symmetric-soliton family is shown in Figure 2 (blue curve in the upper left panel). We have computed the spectra of the linearization operator $L_1$ for these solitary waves, and found that their spectra contain a simple zero eigenvalue at three locations marked by letters “A, B, C” on the power curve. This is evidenced in the upper right panel of Figure 2, where the $L_1$-spectra of solitary waves at these three locations are displayed. Note that at locations “A, B,” the second largest eigenvalue of the spectrum is zero, whereas at location “C,” the largest eigenvalue is zero. At these three locations, solitary waves $u_0(x)$ and eigenfunctions $\psi(x)$ of the zero eigenvalue in $L_1$’s spectra are plotted in the lower row of Figure 2 (as solid blue and dashed red curves, respectively). Note that eigenfunctions $\psi(x)$ at points “A, B” are antisymmetric, whereas the eigenfunction at point “C” is symmetric.

At these “A, B, C” points, zero is a simple discrete eigenvalue of $L_1$, thus Assumption 1 is met and Theorem 1 applies. In addition, for the present example,

$$G_2 = 6u_0 - 20\gamma u_0^3, \quad G_3 = 6 - 60\gamma u_0^2.$$

Now we use our analytical criterion in Theorem 1 to determine if and what bifurcations occur at these points.

At points “A, B,” it is easy to see from symmetry that

$$\langle u_0, \psi \rangle = \langle G_2, \psi^3 \rangle = 0.$$

In addition, when the eigenfunction $\psi$ is normalized to have unit amplitude (see Figure 2, lower row), we find numerically that at point “A,”

$$\langle 1 - G_2L_{10}^{-1}u_0, \psi^2 \rangle = -4.9313, \quad \langle G_3, \psi^4 \rangle - 3\langle G_2, \psi^2, L_{10}^{-1}(G_2\psi^2) \rangle = -58.4035;$$

At these points, zero is a simple discrete eigenvalue of $L_1$, thus Assumption 1 is met and Theorem 1 applies. In addition, for the present example,

$$G_2 = 6u_0 - 20\gamma u_0^3, \quad G_3 = 6 - 60\gamma u_0^2.$$

Now we use our analytical criterion in Theorem 1 to determine if and what bifurcations occur at these points.

At points “A, B,” it is easy to see from symmetry that

$$\langle u_0, \psi \rangle = \langle G_2, \psi^3 \rangle = 0.$$
Figure 2. Bifurcations of solitary waves in Example 1. Upper left: the power diagram; the blue curve is for the family of symmetric solitary waves, and the red curve is for the family of asymmetric solitary waves which bifurcate out from points “A, B” through double pitchfork bifurcations. Upper right: $L_1$’s spectra for solitary waves at bifurcation points “A, B, C” of the power diagram. Lower row: solitary waves $u_0(x)$ and eigenfunctions $\psi(x)$ of $L_1$’s zero eigenvalue at bifurcation points “A, B, C” (the eigenfunctions are normalized to have unit amplitude).

and at point “B,”

$$\langle 1-G_2L_{10}^{-1}u_0, \psi^2 \rangle = 23.9913, \quad \langle G_3, \psi^4 \rangle - 3\langle G_2^2\psi^2, L_{10}^{-1}(G_2\psi^2) \rangle = -110.9244.$$

Then according to Theorem 1, pitchfork bifurcations occur at both “A” and “B” points. In addition, the new (asymmetric) solitary waves bifurcate out on the right side of point “A” and on the left side of point “B.”

At point “C,” we find

$$\langle u_0, \psi \rangle = 6.4879, \quad \langle G_2, \psi^3 \rangle = -21.0632,$$

thus according to Theorem 1, a saddle-node bifurcation occurs at this point. In addition, the bifurcated solutions appear on the left side of point “C.”

These analytical predictions of bifurcations prove to be completely correct. Specifically, at points “A, B,” symmetry-breaking pitchfork bifurcations occur. The two bifurcated asymmetric solitary waves $u^\pm(x; \mu)$ are related to each other by a mirror reflection in $x$, i.e., $u^\pm(-x; \mu) = u^\pm(x; \mu)$, and their power
Figure 3. Power diagram and profiles of solitary waves near the pitchfork bifurcation point “A” in Figure 2. First panel: power diagram; (a, b, c) solitary waves at locations marked by the same letters on the power diagram.

curves (which are identical) are displayed as the red line in Figure 2 (upper left panel). Note that these bifurcated solutions appear on the right side of point “A” and on the left side of point “B,” as predicted by the above analysis. To illustrate solution profiles before and after these bifurcations, we focus on point “A.” The power diagram near this bifurcation point is amplified from that in Figure 2 and shown in Figure 3 (first panel from the left). Note that the power curves near this bifurcation point are linear functions of $\mu$, in agreement with Theorem 2 and Figure 1(b). We have also compared the slopes of the power curves at point “A” in Figure 3 with the analytical power slopes in Equations (15)–(18), and found excellent agreement. At three locations “a, b, c” on the two sides of the bifurcation point “A” in the power diagram, profiles of the solitary waves are displayed in Figures 3(a–c), respectively. Solutions in Figures 3(a, b) are symmetric and lie on the symmetric branch of the power diagram (blue line), whereas the two solutions in Figure 3(c) are asymmetric and lie on the asymmetric (bifurcated) branch of the power diagram (red line). Note that on the left side of the bifurcation point, there is a single (symmetric) solitary wave (see Figure 3a); but on the right side of the bifurcation point, there are three solitary waves, one symmetric (see Figure 3b) and the other two asymmetric (see Figure 3c). These behaviors of the pitchfork bifurcation agree fully with our analytical results as well as the schematic plots in Figure 1(b).

It is interesting to observe from Figure 2 (upper left panel) that the asymmetric soliton branch starts out from point “A” and terminates at point “B,” thus it appears and then disappears through double pitchfork bifurcations. In between, its power curve exhibits a “S” shape, indicating that double saddle-node bifurcations also occur on this asymmetric branch. These features of bifurcations are quite novel for the GNLS equations (1). In a different nonlinear wave system, namely, nonlinear saturable couplers, a similar double pitchfork bifurcation also exists [12].

At point “C” of Figure 2, we have found that a saddle-node bifurcation occurs as predicted. This is already obvious from the power diagram in Figure 2, which shows that the power curve turns around at this point. The power
Figure 4. Power diagram and profiles of solitary waves near the saddle-node bifurcation point “C” in Figure 2. Left panel: power diagram; (a, b) solitary waves at locations marked by the same letters on the power diagram.

diagram near this saddle-node bifurcation point “C” is amplified and shown again in Figure 4. This numerical power curve is compared with the analytical saddle-node power formula (13) and complete agreement is obtained. At two locations “a, b” of the power curve below and above the bifurcation, profiles of the solitary waves are displayed in Figures 4(a, b). These solutions are all symmetric, and their amplitudes vary when going through the bifurcation.

Example 2. Power loop phenomena.

Our second example is still the GNLS equation with opposing cubic and quintic nonlinearities,

\[ iU_t + U_{xx} - V(x)U + |U|^2U - 0.15|U|^4U = 0, \]

but the double-well potential \( V(x) \) is now asymmetric instead:

\[ V(x) = -3.5 \text{sech}^2(x + 1.5) - 3 \text{sech}^2(x - 1.5). \]

This potential is displayed in Figure 5(a). As usual, solitary waves in this equation are sought of the form (2), where \( u(x) \) is a real localized function.

We find that in this system, there exist a family of positive solitary waves whose power curve forms a closed loop. This power loop is displayed in Figure 5(b). This power loop shows that this family of solitary waves has a nonzero minimal power and a finite maximal power, and it exists over a finite propagation constant interval. In addition, four saddle-node bifurcations are clearly visible on this loop. We have checked that at these saddle-node bifurcation points, the bifurcation conditions in Theorem 1 (Case 1) are all satisfied. At four locations of the power loop, three of them (“c, e, f”) being saddle-node bifurcation points and the remaining one (“d”) slightly below a saddle-node bifurcation point, profiles of the solitary waves are displayed in Figures 5(c–f). It is seen that the energy of these solitary waves resides primarily in the shallower (right) well of the potential. Thus, this family of solitary waves is different from the family of ground-state solitary waves in
Figure 5. Power loop phenomenon in Example 2 (i.e., Equation (94)). (a) The asymmetric double-well potential $V(x)$ in Equation (95); (b) the power loop; and (c–f) profiles of solitary waves at locations marked by the same letters on the power loop of (b).

d this system, whose energy resides primarily in the deeper (left) well of the potential. One may notice that this power loop in Figure 5(b) self-crosses itself in the middle (above point “d”). This power-curve crossing does not signal a transcritical bifurcation however, because as $\mu$ approaches this crossing point along the two intersecting curves, the solitary waves do not approach each other. This power loop phenomenon of solitary waves has not been reported before in the GNLS equations (1) (to the author’s knowledge), but a similar momentum loop phenomenon for solitons sitting on constant backgrounds has been discovered in the externally driven NLS equations [27].

Example 3. Transcritical bifurcation.

Our last example is the GNLS equation with competing cubic, quintic, and seventh-power nonlinearities,

$$iU_t + U_{xx} - V(x)U + |U|^2U - 0.2|U|^4U + \kappa|U|^6U = 0,$$  

(96)

where $V(x)$ is the same asymmetric double-well potential (95) as in Example 2, and $\kappa$ is a real constant. In this example, a transcritical bifurcation of solitary waves is found at

$$\kappa = \kappa_c \approx 0.01247946.$$  

(97)

The power diagram of this bifurcation is shown in Figure 6(b). We see that two smooth solution branches, namely, the upper $c_1-c_2$ branch and the lower $d_1-d_2$
branch, tangentially connect at the bifurcation point \((\mu_0, P_0) \approx (3.28, 14.35)\). Profiles of solitary waves at the marked \(c_1, c_2, d_1, d_2\) locations on this power diagram are displayed in Figures 6(c–d). Note that these solutions are close to each other because the \(c_1, c_2, d_1, d_2\) locations are near the bifurcation point \((\mu_0, P_0)\). As \(\mu\) approaches this bifurcation point, we find that these solitary waves along both the lower and upper power branches approach each other, confirming that this is a transcritical bifurcation. Notice that the power diagram in Figure 6(b) agrees with the analytical power formula (19) of transcritical bifurcations (see also the schematic power diagram in Figure 1c). In addition, we have checked the conditions of transcritical bifurcations in Theorem 1 (Case 3), and found them satisfied here as well.

What would happen to the bifurcations in the above three examples if the potential or the nonlinearity in those underlying GNLS equations is slightly perturbed? We have numerically studied this question and found that in Example 1, when the nonlinearity or the potential is slightly and arbitrarily perturbed (including perturbations to make the double-well potential (91) asymmetric), the saddle-node bifurcations (at point “C” of the symmetric-soliton branch and
two others on the asymmetric-soliton branch in Figure 2) always persist. For the two pitchfork bifurcations in this example (at points “A, B” of Figure 2), if the perturbed potential is still symmetric, then these pitchfork bifurcations would survive; but if the perturbed potential becomes asymmetric, then these pitchfork bifurcations are destroyed. In Example 2, the four saddle-node bifurcations on the power loop of Figure 5 always persist under weak perturbations in the nonlinearity or the potential. In Example 3, the transcritical bifurcation is extremely sensitive and is destroyed under generic small perturbations to the system (such as when $\kappa \neq \kappa_c$). From these numerical results, we conclude that saddle-node bifurcations are generic and robust under weak perturbations to the system; pitchfork bifurcations are generally reliant on a symmetric potential; and transcritical bifurcations are very fragile and generally disappear under perturbations. These behaviors are consistent with similar statements on these bifurcations based on the bifurcation conditions below Theorem 1.

### 6. Summary and discussion

In this paper, we classified solitary wave bifurcations in the generalized NLS equations (1) with arbitrary nonlinearities and external potentials in arbitrary spatial dimensions. Sufficient analytical conditions were derived for three major types of solitary wave bifurcations, namely, saddle-node, pitchfork, and transcritical bifurcations. These conditions show that the generic solitary wave bifurcation is the saddle-node bifurcation; the pitchfork bifurcation generally requires certain symmetry conditions; and the transcritical bifurcation is rare. For these bifurcations, shapes of power diagrams near the bifurcation points were also obtained. It was shown that the power diagram for a pitchfork bifurcation exhibits double branching rather than the familiar triple branching, and the power diagram for a transcritical bifurcation features two curves tangentially touching each other rather than the familiar “x”-crossing. Numerical examples for these three types of bifurcations were presented as well. These examples show novel features such as power loops and double pitchfork bifurcations. The example of transcritical bifurcation seems to be the first report of such bifurcation in the GNLS equations (1).

The results in this paper are important not only for a general classification and understanding of solitary wave bifurcations in the GNLS equations (1). More importantly, the bifurcation conditions in Theorem 1 will be the basis for a general treatment of linear stability of solitary waves near bifurcation points. This stability analysis lies outside the scope of the present article and will be reported elsewhere. We do want to say here that the stability properties of solitary waves near bifurcation points in Equation (1) show some important qualitative differences from those in finite-dimensional dynamical systems [25]. Details will be presented in a forthcoming article.
