Von Meyenburg complexes: An atypical presentation

Nikhil S. Kadle, Hammad Liaquat, Saad P. Shaheen II, Luis S. Marsano

ABSTRACT

Introduction: Von Meyenburg complexes are rare, often small multi-nodular cystic lesions which are usually asymptomatic and incidentally diagnosed.

Case Report: We present a case of a 74-year-old male whose medical imaging for follow-up on renal cysts led to an unexpected and incidental diagnosis of Von Meyenburg Complexes. There have been reports of development of cholangiocarcinoma and hepatocellular carcinoma in patients with such lesions.

Conclusion: Von Meyenburg complexes can have atypical presentation and have been associated with hepatobiliary malignancy.
ABSTRACT

Introduction: Von Meyenburg complexes (VMCs) are rare, often small multi-nodular cystic lesions which are usually asymptomatic and incidentally diagnosed. Case Report: We present a case of a 74-year-old male whose medical imaging for follow-up on renal cysts led to an unexpected and incidental diagnosis of Von Meyenburg Complexes. There have been reports of development of cholangiocarcinoma and hepatocellular carcinoma in patients with such lesions. Conclusion: Von Meyenburg complexes can have atypical presentation and have been associated with hepatobiliary malignancy.

INTRODUCTION

Von Meyenburg complexes (VMCs) are uncommon, benign cystic dilatations of the intrahepatic bile ducts surrounded by fibrous stroma [1, 2]. Generally, the size of VMCs is less than 15 mm and they are formed due to ductal plate malformations that occur during embryonic development [3]. The diagnosis of such lesions is usually incidental as patients are usually asymptomatic and have normal liver function. We present a case where VMCs were incidentally diagnosed when evaluating renal cysts in a patient.

CASE REPORT

A 74-year-old African-American male presented with difficulty urinating and abdominal pain. During that admission, he was diagnosed with acute exacerbation of chronic kidney injury and renal ultrasound showed renal cysts up to 3.2 cm on the right and 4.1 cm on the left
kidney. Magnetic resonance imaging scan of abdomen with contrast showed innumerable bilateral renal cysts consistent with polycystic renal disease while the images of the liver revealed multiple areas of heterogeneous T2 hyperintensity with diffusion abnormalities.

Subsequently, an MRI triple phase contrast imaging of the liver reported wedge shaped perfusion abnormalities with corresponding hypervascular areas (Figure 1A–B). There was also central linear branching areas of non-enhancement on the portal venous phase of the imaging which were concerning for thrombosis of the small portal vein branches or an infiltrative disease. The patient’s liver enzyme levels were normal. Further hypercoagulable and liver serological workup was negative. After consultation between physicians and the patient, it was decided that the bleeding risk associated with anticoagulation was high so such treatment was not given. His renal function recovered to baseline with medical management and he was discharged with plan of outpatient nephrology and gastroenterology (GI) evaluation and management.

The patient was seen in GI clinic where a follow-up CT scan triple phase contrast imaging of the liver (Figure 2) showed patchy, heterogeneous enhancement throughout the arterial phase but no diagnosis was reached. Subsequently, the patient underwent liver biopsy which showed grade 2 mild to moderate inflammatory activity and stage 2 peri-portal fibrosis. Foci of bile duct proliferation within collagenous fibrosis were seen which were consistent with bile duct hamartoma (Von Meyenburg complex) (Figure 3A–C). The patient’s liver enzymes remained normal. Subsequent imaging of liver did not show any new pathology. Patient continues to be monitored with ultrasound of liver, liver function laboratory tests as well as follow-up in GI clinic every six months.

**DISCUSSION**

Von Meyenburg complexes (VMCs), or bile duct hamartomas are benign liver lesion that have a prevalence of 0.69–2.8% in the population [4]. VMCs are associated with autosomal dominant polycystic kidney disease (ADPKD), Caroli disease and congenital hepatic fibrosis [5–7]. Our patient was diagnosed with ADPKD which has a prevalence 11% in adults with at least one VMC and 40% in those with four or more such lesions in a large study involving autopsies [5]. The same study found the overall prevalence of VMCs in livers on autopsy to be 5.6%.

Von Meyenburg complexes are generally asymptomatic and do not cause liver enzyme abnormalities, although there have been cases where patients have presented initially with abdominal pain [6]. Our patient was asymptomatic at presentation and diagnosis.

An MRI scan is superior to both ultrasound and CT scan to diagnose these lesions where VMCs are often seen

**Figure 1:** Magnetic resonance imaging scan of abdomen with and without contrast – Focal hypervascular areas described as hyper-intense on T2 imaging and bright on diffusion weighted images with persistent nonspecific diffusion abnormalities throughout the liver. (A) T2 weighted MRI image, and (B) Diffusion weighted MRI image.

**Figure 2:** Computed tomography scan with and without contrast (liver protocol) – Arterial phase consistent with patchy, heterogeneous enhancement throughout the liver.

**Figure 3:** (A–C) Liver biopsy - Grade 2 mild to moderate peri-portal fibrosis. Foci of fibrosis and bile duct proliferation are consistent with bile duct hamartomas (Von Meyenburg complex). (A) H&E stain, x100, (B) H&E stain, x400, (C) Masson’s Trichrome stain, x400.
as irregular T2 hyperintense cystic nodules throughout the liver without communication of these lesions with the biliary tree [6]. Most VMCs appear with hypointense T1 and hyperintense T2 MRI imaging [2]. Our patient’s MRI showed similar though non-specific characteristics of the lesions. However, some sources also note that it can be difficult to definitively diagnose VMCs by MRI as T1-weighted sequences can show both enhancement and no enhancement [6]. The presence of cystic lesions with surrounding fibrous stroma and congested interfaces may account for the variation in appearance [2].

A liver biopsy is required if lesions have atypical characteristics and remain undiagnosed on MRI scan [6]. Since there was concern for an infiltrative process, liver biopsy was performed and definitively diagnosed VMCs in our patient.

There have been reports of development of cholangiocarcinoma and hepatocellular carcinoma (HCC) in patients with VMCs [6, 8, 9]. The exposure of the biliary epithelium to chronic cholestasis is thought to lead towards neoplastic transformation. Although there are currently no guidelines for follow-up of patients with VMCs, such patients could be followed per guidelines for patients at risk of cholangiocarcinoma and HCC.

**CONCLUSION**

Von Meyenburg complexes (VMCs) are uncommon lesions of the liver. Medical imaging, particularly MRI, is usually diagnostic. Our patient had an atypical presentation of VMCs on MRI and required liver biopsy for diagnosis. Hepatobiliary malignancy has been reported in patients with such liver lesions so regular follow up including medical imaging and liver function tests could be done after VMCs have been diagnosed in a patient.

Edorium Journals: An introduction

Edorium Journals Team

About Edorium Journals
Edorium Journals is a publisher of high-quality, open access, international scholarly journals covering subjects in basic sciences and clinical specialties and subspecialties.

Invitation for article submission
We sincerely invite you to submit your valuable research for publication to Edorium Journals.

But why should you publish with Edorium Journals?
In less than 10 words - we give you what no one does.

Vision of being the best
We have the vision of making our journals the best and the most authoritative journals in their respective specialties. We are working towards this goal every day of every week of every month of every year.

Exceptional services
We care for you, your work and your time. Our efficient, personalized and courteous services are a testimony to this.

Editorial Review
All manuscripts submitted to Edorium Journals undergo pre-processing review, first editorial review, peer review, second editorial review and finally third editorial review.

Peer Review
All manuscripts submitted to Edorium Journals undergo anonymous, double-blind, external peer review.

Early View version
Early View version of your manuscript will be published in the journal within 72 hours of final acceptance.

Manuscript status
From submission to publication of your article you will get regular updates (minimum six times) about status of your manuscripts directly in your email.

Our Commitment

Six weeks
You will get first decision on your manuscript within six weeks (42 days) of submission. If we fail to honor this by even one day, we will publish your manuscript free of charge.*

Four weeks
After we receive page proofs, your manuscript will be published in the journal within four weeks (31 days). If we fail to honor this by even one day, we will publish your manuscript free of charge and refund you the full article publication charges you paid for your manuscript.*

Favored Author program
One email is all it takes to become our favored author. You will not only get fee waivers but also get information and insights about scholarly publishing.

Institutional Membership program
Join our Institutional Memberships program and help scholars from your institute make their research accessible to all and save thousands of dollars in fees make their research accessible to all.

Our presence
We have some of the best designed publication formats. Our websites are very user friendly and enable you to do your work very easily with no hassle.

Something more...
We request you to have a look at our website to know more about us and our services.

* Terms and condition apply. Please see Edorium Journals website for more information.

We welcome you to interact with us, share with us, join us and of course publish with us.
