1 Introduction

Numerous theories have been considered to understand the striking difference between quark and lepton mixings and their mass hierarchies. A promising approach is the introduction of flavor symmetries. An example are spontaneously broken flavor symmetries generating masses from higher-dimension terms via the Froggatt-Nielsen mechanism [1]. In such approaches, effective dimension-$n$ mass terms, proportional to $e^n$, arise, where $e$ depends on the flavon vacuum expectation value (VEV) suppressed by the mass of super-heavy fermions. In this way, mass matrix textures with $e$-powers as entries are obtained. Consequently, such a matrix structure contains information on the hierarchy among matrix elements and goes beyond approaches, e.g., using texture zeros.

However, many flavor symmetries and scenarios of mass generation are possible. Therefore, we suggest in [2, 3] a systematic bottom-up approach. Thereby, we do not start with a symmetry to generate textures. Instead, we systematically construct a comprehensive list of mass matrix textures from very generic assumptions, for effective lepton masses and for the seesaw mechanism [4]. In our approach, we parameterize all mass generations are possible. Therefore, we suggest in [2, 3] a systematic bottom-up approach. Thereby, we do not start with a symmetry to generate textures. Instead, we systematically construct a comprehensive list of mass matrix textures from very generic assumptions, for effective lepton masses and for the seesaw mechanism [4]. In our approach, we parameterize all mass matrix textures from very generic assumptions, for effective lepton masses and for the seesaw mechanism [4]. In our approach, we parameterize all

2 Effective Mass Matrices

In the Standard Model with massive Majorana neutrinos, the effective lepton mass terms have the form

$$L_M = -(M_i)_{ij} e_i^c e_j^c - \frac{1}{2} (M^M_{ij})_{ij} \nu_i \nu_j + h.c.,$$

where $e_i$ and $\nu_i$ are the left-handed charged leptons and neutrinos, $e_i^c$ the right-handed charged leptons, and $i = 1, 2, 3$ is the generation index. The mass ratios of charged leptons and normal hierarchical (NH) neutrinos are roughly given as

$$m_e : m_\mu : m_\tau = e^4 : e^2 : 1,$$

$$m_1 : m_2 : m_3 = e^2 : e : 1.$$ (2)

The best-fit values of the mixing angles of the lepton mixing matrix (cf., tribimaximal mixing [6])

$$U_{PMNS} = U^T_l U_\nu = \tilde{U}_\ell D_\nu \tilde{U}_\nu K_\nu$$

are

$$\theta_{12} = \pi/4 - \epsilon, \quad \theta_{13} = 0, \quad \theta_{23} = \pi/4,$$ (4)

where $U_{PMNS}$ is on the standard form, $U_\ell$ and $U_\nu$ are the charged lepton and neutrino mixing matrices respectively, $\tilde{U}_\ell$ and $\tilde{U}_\nu$ are CKM-like matrices, $D_\nu = \text{diag}(1, e^{i\theta_1}, e^{i\theta_2})$, and $K_\nu = \text{diag}(e^{i\bar{\theta}_1}, e^{i\bar{\theta}_2}, 1)$. Note that we have removed unphysical phases and have used the parameterization of a general unitary $3 \times 3$ matrix

$$U_{\text{unitary}} = D \tilde{U}_K.$$ (5)

In this talk we restrict ourselves to NH. However, in [2, 3] we also discuss scenarios of inverted hierarchical and degenerate neutrinos.
Here, $D$ and $K$ are diagonal phase matrices, i.e., $D = \text{diag}(\epsilon e^{i\phi_1}, \epsilon e^{i\phi_2}, \epsilon e^{i\phi_3})$, $K = \text{diag}(e^{i\alpha_1}, e^{i\alpha_2}, 1)$, and $\hat{U}$ is a CKM-like matrix. The mass matrices are diagonalized by

$$M_{\ell} = U_{\ell} M^{\text{diag}}_{\ell} U_{\ell}^T, \quad M^\text{Ma}_\nu = U_\nu M^\text{diag}_\nu U^T_\nu,$$

where the mass matrices, in the mass basis, are $M^{\text{diag}}_{\ell} = m_{\ell} \text{diag}(e^4, e^2, 1)$ and $M^\text{diag}_\nu = m_\nu \text{diag}(e^2, \epsilon, 1)$.

From Eq. (3), one can see that more than one combination of $U_{\ell}$ and $U_\nu$ can lead to the same PMNS mixing matrix. This ambiguity could be circumvented, e.g., by rotating to the basis where the charged leptons are diagonal, or by using invariants. However, we should keep in mind the origin of $U_{\ell}$ and $U_\nu$, i.e., that the mass matrices might be generated by a flavor symmetry. Therefore, we do not use such a simplification in our model-independent bottom-up approach in order not to loose or conceal this information. Later, we will identify the origin of our mass matrix textures by explicit models from flavor symmetries.

In order to obtain a comprehensive set of realistic mass matrices, we extend the parameterization described above and use the hypothesis of extended quark-lepton complementarity, i.e., all masses and mixings are powers of a small quantity $\epsilon \sim \theta_C$. For the mixings, $\epsilon^0$ is interpreted as $\pi/4$. Therefore, we generate all possible combinations of Eq. (6) with $\theta_{12}^\ell \in \{\pi/4, \epsilon, e^2, 0\}$ and phases 0 or $\pi$, where $x \in \{\ell, \nu\}$. We have truncated the series of $\theta_{12}^\ell$ after $e^2$ and approximate $e^n = 0$ for $n > 2$, since this corresponds to the present experimental precision. In order to obtain the textures, we have expanded the mass matrices to second order in $\epsilon$ about $\epsilon = 0$, and identified each element with its leading order in $\epsilon$. An obvious advantage of this method is that no diagonalization is needed. Out of the 262 144 obtained combinations, 2 468 are compatible with current experiments at the 3$\sigma$ CL.

In Fig. 1 we show the mixing angle distributions for these combinations. One can see that most of the cases could be tested in future experiments. The corresponding lepton mass matrices are obtained with Eq. (6). As an example of our results we show in Table 1 textures #17 and 18 of [2] with a perfect fit to tribimaximal mixing [6] (the complete list including a notebook can be found in [2]). Thereby, we set $U_\nu = 1$ since it does not affect any observables.

In Table 1 we call the new texture of $M^\text{Ma}_\nu$ “diamond” texture because it has only one entries in the corners. A general feature of this kind of textures is that

\[ \theta_{12}^\ell, \theta_{13}^\ell, \theta_{23}^\ell \]

\[ (\delta^\ell, \delta^\nu, \tilde{\phi}_1, \tilde{\phi}_2) \]

\[ (\theta_{12}^\ell, \theta_{13}^\ell, \theta_{23}^\ell) \]

\[ (\delta^\ell, \delta^\nu, \tilde{\phi}_1, \tilde{\phi}_2) \]

Note, since usually more than one Yukawa coupling matrix leads to the same texture, we choose the one that fits experimental data best.

However, note that $M_{\ell}$ depends, in contrast to $U_{\text{PMNS}}$, on $U_{\ell}$.

Fig. 1. Distributions of sin$^2 \theta_{13}$ (left), sin$^2 \theta_{23}$ (middle), and sin$^2 \theta_{12}$ (right) of Yukawa coupling matrices for $\epsilon = 0.2$ (figure taken from [2]). The bars show the number of selected Yukawa coupling matrices per bin, i.e., per specific parameter range. The gray-shaded regions mark the current 3$\sigma$-excluded regions.

Table 1. Selected examples of mass matrix textures from [2]. For the mass matrices of charged leptons we use the basis in which the mixings of the right-handed fields are zero. Shown are also the corresponding mixing angles and phases of $U_{\ell}, U_\nu$ (with $\xi \in \{0, \pi\}$), as well as the mixing angles of $U_{\text{PMNS}}$. 

| #  | $M_{\ell}$ | $M^\text{Ma}_\nu$ | $(\theta_{12}^\ell, \theta_{13}^\ell, \theta_{23}^\ell)$ | $(\theta_{12}^\ell, \theta_{13}^\ell, \theta_{23}^\ell)$ | $(\theta_{12}^\ell, \theta_{13}^\ell, \theta_{23}^\ell)$ |
|----|-----------|------------------|-------------------------------------------------|-------------------------------------------------|-------------------------------------------------|
| 17 | (0 $\epsilon^2$ $\epsilon$) | (1 $\epsilon^2$ $\epsilon$) | ($\pi/4, \epsilon, e^2, 0$) | ($\theta_{12}^\ell, \theta_{13}^\ell, \theta_{23}^\ell$) | ($\delta^\ell, \delta^\nu, \phi_1, \phi_2$) |
| 18 | (0 $\epsilon^2$ $\epsilon$) | (1 $\epsilon^2$ $\epsilon$) | ($\pi/4, \epsilon, e^2, 0$) | ($\theta_{12}^\ell, \theta_{13}^\ell, \theta_{23}^\ell$) | ($\delta^\ell, \delta^\nu, \phi_1, \phi_2$) |
that $\theta'^{\prime}_{13} = \pi/4$. This texture is a direct result of our systematic approach. In addition, we have found new sum rules, e.g., for the textures in Table 1, we obtain

$$\theta_{12} + \frac{3}{5 + 2\sqrt{2}} \epsilon = \arctan(2 - \sqrt{2}).$$

(7)

This should be compared with our result corresponding to the usual quark-lepton complementarity relation [5]

$$\theta_{12} + \frac{\epsilon}{\sqrt{2}} + \frac{\epsilon^2}{\sqrt{2}} = \frac{\pi}{4},$$

(8)

which we have, of course, obtained as a special case from our procedure, as expected.

3 Type-I Seesaw

Our procedure above can also be extended to the (type-I) seesaw mechanism [4]. In that mechanism, the mass terms for the charged leptons, Dirac and Majorana neutrinos are

$$\mathcal{L}_{\text{mass}} = -(M_D)_{ij} \bar{e}_i \nu^c_j - (M_D)_{ij} \nu_i \nu^c_j - \frac{1}{2} (M_R)_{ij} \nu^c_i \nu_j + \text{h.c.}$$

(9)

The mass matrices are diagonalized by

$$M_L = U_L M^\text{diag}_L U_L^\dagger, \quad M_D = U_D M^\text{diag}_D U_D^\dagger, \quad M_R = U_R M^\text{diag}_R U_R^\dagger, \quad M^\text{eff} = U_c M^\text{diag}_c U_c^\dagger,$$

(10)

where the effective neutrino mass matrix is given by the seesaw formula

$$M^\text{eff} = -M_D M_R^{-1} M^\dagger_D.$$

(11)

Together with the parameterization in Eq. 5, we obtain

$$M^\text{eff}_\text{th} = -D_D \bar{D_D} \tilde{K} M^\text{diag}_D \bar{U_D} \bar{U_D}^\dagger \bar{D_D} (K_R^D)^3 \times (M^\text{diag}_R)^{-1} \bar{U_R} \bar{D_R}^\dagger M^\text{diag}_R \tilde{K} \bar{U_R} \bar{D_R} D_R,$$

(12)

where we have introduced $\tilde{K} = K^2_D K_{D^c}$, and $\bar{D} = D_D^\dagger D_R$. If we use, on the other hand, the experimentally known PMNS matrix in Eq. 3 together with Eq. 4, and insert it into Eq. 10, we obtain

$$M^\text{exp}_\text{eff} = D_D \bar{U_D} K_D \bar{U}_{PMNS} K^2_{Maj} \times M^\text{diag}_D \bar{U}_{PMNS} K_{D^c} \bar{U_D} \bar{D_D}.$$

(13)

Since both $M^\text{eff}_\text{th}$ and $M^\text{exp}_\text{eff}$ describe the same mass matrix, they are identical. Therefore, we match $M^\text{eff}_\text{th}$ and $M^\text{exp}_\text{eff}$ with a precision of $\epsilon^3$. In this way, we circumvent the diagonalization of $M^\text{eff}_\text{th}$. For the resulting mass matrices, we show in Fig. 2 the distribution of their mass hierarchies, and in Fig. 3 the fraction of special cases often considered in literature. There, one can see that in most cases, $M^\text{eff}_\text{th}$ has degenerate mass matrices which could be used for resonant leptogenesis. Just a small fraction has a strictly hierarchical mass spectrum in $M^\text{eff}_\text{th}$, which would be preferred in usual leptogenesis scenarios. Special cases, such as symmetric $M_D$, diagonal $M_R$, and $U_\ell \simeq 1$, of all allowed Yukawa coupling matrices (figure taken from [3]). This figure is based on the mixing matrices, where $U_D \simeq U_{D^c}$, with $U_{D^c}$, $U_R \simeq 1$, and $U_\ell \simeq 1$ in the second and third case, respectively. For the similarity condition “$\sim$”, we allow for $\epsilon^2$-deviations in the mixing angles. For instance, for an exact $U_R = 1$, one would have only 2% of all Yukawa coupling matrices.
Table 2. Selected examples of seesaw textures and Yukawa coupling matrices from [3].

Table 3. Assignment of flavor changes to the leptons. The models 1 and 2 lead respectively to the textures #17 and 18 in Table 2 (table taken from [3]).

4 Outlook

In this talk, we have presented a comprehensive list of textures for effective lepton masses and for the seesaw mechanism. The mass matrices are obtained via the hypothesis of extended quark-lepton complementarity, i.e., all masses and mixings are assumed to be powers of $\epsilon \sim O(\theta_C)$. For the mixings, the zeroth order in $\epsilon$ is interpreted as a maximal mixing angle $\pi/4$.

As a direct consequence of our systematic approach, we have obtained at least one new texture and a new sum rule. In addition, we have shown the distribution of PMNS mixing angles and how they could be tested by future experiments. We have also shown that only a small fraction of our results would favor usual leptogenesis scenarios, while most of the cases could be used for resonant leptogenesis. Also special cases of symmetric $M_D$ and $M_R$ are just a small fraction of less than 1%, whereas diagonal $M_R$ represents 24% of all resulting cases. A more sophisticated analysis can be found in [2,3]. This includes details of our procedure, the complete list of textures, the discussion of inverted hierarchical and degenerate neutrinos, variations of $\epsilon$ and Dirac phases, distributions for $0\nu\beta\beta$ etc.

We have also shown how our textures can be generated in explicit models from flavor symmetries. This could be regarded as proof of principle that our approach can be used both to explore the parameter space in a possibly less biased way as well as for model building. Thereby, a systematic identification of flavor symmetries for textures could be done in an “automated” way.
