**Abstract:** New antifungals with unique modes of action are urgently needed to treat the increasing global burden of invasive fungal infections. The fungal inositol polyphosphate kinase (IPK) pathway, comprised of IPKs that convert IP₃ to IP₆₄, provides a promising new target due to its impact on multiple, critical cellular functions and, unlike in mammalian cells, its lack of redundancy. Nearly all IPKs in the fungal pathway are essential for virulence, with IP₃-₄ kinase (IP₃-₄K) the most critical. The dibenzylaminopurine compound, N₂-(m-trifluorobenzylamino)-N₆-(p-nitrobenzylamino)purine (TNP), is a commercially available inhibitor of mammalian IPKs. The ability of TNP to be adapted as an inhibitor of fungal IP₃-₄K has not been investigated. We purified IP₃-₄K from the human pathogens, Cryptococcus neoformans and Candida albicans, and optimised enzyme and surface plasmon resonance (SPR) assays to determine the half inhibitory concentration (IC₅₀) and binding affinity (Kₘ), respectively, of TNP and 38 analogues. A novel chemical route was developed to efficiently prepare TNP analogues. TNP and its analogues demonstrated inhibition of recombinant IP₃-₄K from C. neoformans (CnArg1) at low µM IC₅₀, but not IP₃-₄K from C. albicans (CalpK2) and many analogues exhibited selectivity for CnArg1 over the human equivalent, HsIPMK. Our results provide a foundation for improving potency and selectivity of the TNP series for fungal IP₃-₄K.

**Keywords:** inositol polyphosphate kinase; IP₃-₄K; TNP; dibenzylaminopurine; fungal pathogens; antifungal drug discovery; structure activity relationship; Cryptococcus neoformans; enzyme assay; surface plasmon resonance

1. Introduction

Invasive fungal diseases affect over 300 million people and cause greater than 1.5 million deaths annually around the world, matching deaths from tuberculosis and exceeding those from malaria [1,2]. Cryptococcus neoformans and drug-resistant Candida species are high on a list of a soon-to-be-released fungal priority pathogens established by the WHO. C. neoformans is an environment yeast that initially infects the lungs but has a predilection for the central nervous system where it causes meningoencephalitis. C. albicans is a component of the human mycobiota and causes candidemia.

Despite the high rates of morbidity and mortality due to invasive fungal diseases, our antifungal drug armamentarium has limitations and is confined to four classes that
predominantly inhibit fungal sterols (ergosterol) and/or their synthesis, and synthesis of the
cell wall. Prolonged use of the polyenes, which target fungal ergosterol (e.g., Amphotericin
B), can cause kidney failure [3]. The azoles, the most advanced class, inhibit fungal growth
but do not kill fungi and drug resistance is a major concern [4]. Increased human exposure
to azoles used in agriculture and farming, coupled with prolongedazole treatment in
the clinic, are thought to be major drivers of resistance andazole cross-resistance [4,5].
The echinocandins (target cell wall synthesis) have a limited antifungal spectrum with no
activity against C. neoformans [6,7]. Furthermore, echinocandin-resistant strains, including
the multi-drug resistant C. auris [8], are emerging and pose a serious global health threat.
Thus, there is an urgent need to develop new antifungal drug classes with novel targets.

Recent studies in C. neoformans and C. albicans have shown that the inositol polyphos-
phate (IP) kinase (IPK) pathway is a promising target for antifungal drug development due
to its involvement in numerous critical cellular processes (reviewed in [9–12]). The fungal
IPK pathway is comprised of a series of sequentially acting IPKs that convert IP₃ to IP₈,
with IP₃-K the most critical for virulence and cellular function in both C. neoformans [13–16]
and C. albicans [17–19]. IP₆K (Kcs1) and its product, IP₇, are also essential for the virulence
of C. neoformans [15].

In contrast to fungi, the product of IP₃-K, IP₅, can be generated by more than one
route in human and involves 4 different enzymes: inositol polyphosphate multikinase
(HsIPMK), IP3K, INPP5 and ITPK1 (reviewed in [10,11]). In addition to having IP₃-K activity,
HsIPMK functions as a phosphoinositide 3-kinase [20–22] and as a scaffold protein
in the target of rapamycin (TOR) where its enzymatic activity is not required [23] (reviewed
in [24]). HsIP6K has been implicated in various health conditions including cancer [25,26],
aging [27] and diabetes and obesity [28].

Based on the critical role of the IPK pathway in fungal virulence and the redundancy in
the human pathway, targeting fungal IP₃-K is a promising strategy for developing a novel
class of antifungal drug. Firstly, IP₃-K is a different target to the current antifungal drug
targets and impacts numerous cellular functions critical for virulence rather than a single
function. Secondly, fungal and human IP₃-Ks share a low amino acid sequence homology,
with commonality restricted to a few key catalytic residues [11]. Thirdly, IPK function is
non-redundant in fungi, with each step catalysed by a single enzyme. This is in contrast
to mammalian cells where the pathway is more branched, with at least 3 IPKs catalysing
the conversion of IP₃ to IP₅. The latter points suggest that inhibitors specific for the fungal
enzyme can be generated without detrimentally impacting the human IPK pathway.

The search for human IPK inhibitors, especially IP6K inhibitors, to serve as metabolic
regulators has been ongoing for over 20 years with several promising potent molecules
produced (reviewed in [29]). The spiro-oxindole-based compounds SC-919 [30], LI-2242
and LI-2172 [31] possess nanomolar potencies against all HsIP6K isoforms in vitro. The
benzoisoxazole-based UNC7467 achieved selectivity for IP6K1 and IP6K2 with nanomo-
lar potencies compared to IP6K3 [32]. Currently, N2-(m-trifluorobenzylamino)-N6-(p-
nitrobenzylamino) purine (TNP), is the only commercially available IPK inhibitor (reviewed
in [29]). TNP has a dibenzylaminopurine scaffold in which two benzyl rings are attached at
positions N2 and N6 of the purine structure. TNP is an ATP-competitive inhibitor of all
three IP6K isoforms in mammalian cells [33] and was discovered through a purine-based
compound library screen against human IP3K [34]. However, TNP was later found to be
more potent against IP6K, with an IC₅₀ of 0.47 µM [33] compared to an IC₅₀ of 10 µM
against IP3K [34], and demonstrated anti-obesity and anti-diabetic effects in a mouse model
of high fat diet-induced obesity [28,35]. Although TNP is a potent inhibitor of human IP6K,
it does not inhibit rat IPMK at a concentration of 10 µM [36] and its inhibitor properties
against human IPMK have not been determined.

As a probe and drug, TNP has low water solubility, which negatively impacts its
potency, and has off-target effects [28,35]. Using medicinal chemistry approaches, it was
shown that modifications could be introduced to TNP to improve its solubility and selec-
tivity for the different IP6K isoforms, with a preference for IP6K1 [37], providing proof-of-
principle that selectivity of TNP for other IPKs in the same family, including IP3-4Ks, can be achieved. In a separate study, the modification of TNP was able to reduce off-target effects by reducing inhibition of the cytochrome P450 enzyme CYP3A4 [35].

TNP treatment of the non-pathogenic yeast, *Saccharomyces cerevisiae*, reduces IP7 levels and phenocopies an IP6K deletion mutant by causing vacuolar fragmentation [33,38], consistent with TNP targeting yeast IP6K. However, the potency of TNP as an inhibitor of fungal IPKs in vitro was not assessed. Here, we purify tag-free IP3-4K from *C. neoformans* (CnArg1) and *C. albicans* (CaIpk2), and HsIPMK and assess the potency and selectivity of inhibition of TNP and 38 derivatives using an optimised enzyme assay and a newly developed surface plasmon resonance (SPR) assay.

2. Materials and Methods

2.1. Strains and Media

*Yeast strains*: Cryptococcus neoformans var grubii (strain H99) (serotype A, MATα) and *Candida albicans* (strain SC5314), used to produce IP3-4K cDNA, were routinely grown on YPD (1% yeast extract, 2% peptone and 2% dextrose). *Bacterial strains*: One Shot™ TOP10 chemically competent *E. coli* (Invitrogen™, Waltham, MA, USA) were used for transformation and plasmid storage (high-copy plasmid). The chemically competent BL21 (DE3) *E. coli* strain was used for protein expression. *E. coli* strains were routinely grown in LB broth (1% tryptone, 0.5% yeast extract, 0.5% NaCl) or LB Agar (same recipe as broth with 1.5% agar) with or without Ampicillin (100 µg/mL) to retain plasmids. S.O.C media (2% tryptone, 0.5% yeast extract, 0.05% NaCl, 2.5 mM KCl, 20 mM glucose, 5 mM MgCl2, pH 7) and LB broth were used for post-transformation cell recovery.

2.2. RNA Extraction and cDNA Synthesis

The mRNA sequences of Arg1 in *Cryptococcus neoformans* (NCBI Reference Sequence: XM_012198137.1) and Ipk2 in *Candida albicans* (NCBI Reference Sequence: XM_709458.2) were retrieved from the NCBI database. RNA was extracted from each strain using TRIzol™ (Invitrogen) as per the protocol described in [14,39]. Briefly, YPD overnight-grown fungal cells were pelleted by centrifugation and snap-frozen in liquid nitrogen. TRIzol™ and 425–600 µm glass beads (Sigma, St. Louis, MO, USA) were added to the cell pellets, which were homogenised by bead-beating. RNA was extracted following the manufacturer’s instructions, residual DNA was removed by RQ DNasel treatment (Promega) and cDNA was synthesized using Moloney Murine Leukemia Virus Reverse Transcriptase (Promega).

2.3. Cloning of IP3-4K into the pGEX-6P Expression Vector

pGEX-6P_CnArg1 and pGEX-6P_CaIpk2: IP3-4K cDNA created above was used as a template to PCR-amplify CnArg1 using primers ARG1-BgIII-s and ARG-EcoRI-a and CaIpk2 with primers CalPK2-BamHI-s and CalPK2-XhoI-a (see Table 1), using Invitrogen™ Platinum™ Taq High Fidelity DNA Polymerase. The PCR products were cloned into the pGEX-6P expression vector, and transformed into TOP10 competent cells. Colonies were screened by colony PCR using primers pGEX-Seq-s and pGEX-Seq-a to identify those with the correct insert. The inserts were sequenced to confirm the absence of PCR-induced mutations by comparison to the NCBI database, and that the cDNA was in-frame with the GST to ensure proper translation.

pGEX-6P_HsIPMK: human IPMK (ORF NM_152230.5) cloned into pGEX-6P. This plasmid was ordered from GenScript using their Express Cloning service including sequencing by GenScript to ensure the correct sequence was provided.
Table 1. Primers used to construct and verify expression plasmids.

| Primer Name     | Primer Sequence (5′ to 3′)                     | Description                                                                 |

2.4. Expression and Purification of IP3-4K Proteins

pGEX-6P_CnArg1, pGEX-6P_CaIPK2 and pGEX-6P_HsIPMK plasmids were used to transform chemically competent BL21 (DE3) cells. Transformed BL21 (DE3) cells were used to inoculate LB-Ampicillin broth grown overnight at 37 °C with shaking. This starter culture was used to seed fresh LB-Ampicillin medium (1:200 dilution), which was then incubated at 37 °C with shaking until the OD600 reached 0.6. IPTG (1 mM) was then added to induce protein expression overnight. Cells were harvested and the cell pellet was resuspended in GST lysis buffer (20 mM HEPES, pH 7.3, 100 mM NaCl, 1 mM EDTA, 1 mM EGTA, 0.5% Triton X-100, 2 mM DTT, 1 mM PMSF, Roche Complete™ Protease Inhibitor Mini Tablets, EDTA-free), probe-sonicated and centrifuged to remove debris. The cleared lysate (supernatant) containing soluble GST-tagged fusion protein was then collected and subjected to two rounds of purification.

The first purification step involved incubating the clear lysate with Glutathione sepharose® 4B (GE Life Sciences, Chicago, IL, USA) beads at 4 °C with gentle end-to-end rotation. The suspension was then added to an empty column for gravity flow chromatography, and unbound proteins (flow-through) were separated from bead-bound proteins. The beads were then washed 6 times with 3 column volumes of the following ice-cold buffers each time: twice with lysis buffer, twice with wash buffer 1 (50 mM Tris-HCl, pH 7.5, 500 mM NaCl, 2 mM EDTA, 1 mM EGTA, 1% Triton X-100, 2 mM DTT) and twice with wash buffer 2 (50 mM Tris-HCl, pH 8.0, 150 mM NaCl, 2 mM DTT). For protein elution, the washed beads were incubated in elution buffer (50 mM Tris-HCl, pH 8.0, 150 mM NaCl, 2 mM EDTA, 2 mM DTT, 150 µg/mL GST-HRV 3C protease) at 4 °C overnight with gentle end-to-end rotation. The eluted protein solution was then collected, and the beads were further washed with wash buffer 2 to maximise protein recovery. All the eluted protein was pooled and concentrated using an Amicon® Ultra-15 mL Centrifugal Filter Unit (Merck Millipore, Burlington, MA, USA) with a 10 kDa molecular weight cut-off (MWCO).

The second purification step involved size exclusion chromatography (SEC) using an AKTA Fast Protein Liquid Chromatography (FPLC) system (GE Life Sciences, Chicago, IL, USA) with a HiLoad 26/600 Superdex 75 pg column (GE Life Sciences, Chicago, IL, USA). Fractions were collected, pooled and concentrated using an Amicon® Ultra-15 mL Centrifugal Filter Unit (Merck Millipore, Burlington, MA, USA) with a 10 kDa MWCO. Enzyme purity and size were assessed by SDS-PAGE (4–12% Bis-Tris protein gel). The protein multimerization state and a more accurate molecular weight were determined using
2.5. Determination of $K_m$ and $V_{\text{max}}$ for ATP

The kinetic properties of the purified recombinant enzymes were determined and compared using a Kinase-Glo® Max Luminescent Kinase Assay kit (Promega, Madison, WI, USA) in a reaction buffer consisting of 20 mM HEPES pH 6.8, 100 mM NaCl, 6 mM MgCl$_2$, 20 µg/mL BSA, 1 mM DTT [14]. The IP$_3$ concentration was fixed at 200 µM. The ATP starting concentrations ranged between 25 µM to 400 µM and the ATP remaining after up to 10-min reaction time was assessed by adding Kinase-Glo® reagent. An ATP standard curve (0–500 µM) was also generated using the same kit. The ATP concentration remaining was measured as luminescence using a SpectraMax iD5 plate reader. The relative luminescence unit (RLU) was converted to ATP concentration using the ATP standard curve. The reaction velocity was calculated for each starting ATP concentration and the data was fitted to the Michaelis-Menten equation using GraphPad Prism 9 to obtain $V_{\text{max}}$ and $K_m$ values.

2.6. Enzyme Activity and Inhibition Assay to Screen for ATP-Competitive Inhibitors

The 2,6-disubstituted purine compounds are ATP-competitive IPK inhibitors. The screening assay was therefore set up to favour screening of ATP-competitive inhibitors following the manufacturer’s suggestion. This involved using 10 µM ATP and a Kinase-Glo kit that measures up to 10 µM ATP (Kinase-Glo® Luminescent Kinase Assays, Promega, Madison, WI, USA). The amount of IP$_3$ and kinase used for each recombinant enzyme was determined following the manufacturer’s instructions, and this concentration was used to assess the inhibitory properties of TNP analogues against each of the recombinant enzymes.

The assay was carried out in reaction buffer (20 mM HEPES pH 6.8, 100 mM NaCl, 6 mM MgCl$_2$, 20 µg/mL BSA, 1 mM DTT) containing 10 µM ATP and the optimal amount of IP$_3$ and enzyme determined via the optimisation process in a final volume of 50 µL. The analogues were dissolved in DMSO. For the assay, the inhibitors were added to the reaction mixture to achieve a final concentration of 50 µM in 5% DMSO (1:20 dilution). To achieve inhibitor concentrations lower than 50 µM in the assay, the inhibitor stock was first serially diluted two-fold in DMSO and added to the reaction mixture, to achieve concentrations ranging between 0.8 µM and 50 µM in 5% DMSO. Once all analogues and their dilution series had been added, the reaction was started by adding an optimal amount of recombinant IP$_3$-qK enzyme. The reaction was stopped after 10-min incubation at room temperature by adding a 50 µL of Kinase-Glo® reagent. The mixture was incubated at room temperature in the dark for 10–15 min. Luminescence (RLU) was measured using a SpectraMax iD5 and an integration time of 0.5 s. Percent enzyme activity was defined as $(\text{RLU}_{\text{negative}} - \text{RLU}_{\text{sample}})/(\text{RLU}_{\text{negative}} - \text{RLU}_{\text{positive}}) \times 100$. ‘Positive’ refers to 100% enzyme activity (no inhibitor used as the positive control), while ‘negative’ refers to 0% enzyme activity (no enzyme used as the negative control). The IC$_{50}$ was calculated using GraphPad Prism 9 by plotting the RLU, which indicates the ATP concentration remaining, against the concentration of TNP analogue.

2.7. Surface Plasmon Resonance (SPR) to Assess Binding Affinity of TNP Analogues

SPR was carried out on a Biacore T200 (Cytiva, Marlborough, MA, USA). A streptavidin surface was prepared by amine coupling streptavidin to a CM5 chip using standard procedures in 20 mM HEPES, 150 mM NaCl pH 7.5 at 37 °C. Briefly, the surface was activated by injection of 1:1 NHS:EDC (N-ethyl-N’-(3-(dimethylamino)propyl)carbodiimide/N-hydroxysuccinimide) followed by a 7-min injection of 100 µg/mL streptavidin in 10 mM sodium acetate (pH 4.5) at a flow rate of 2 µL/min. Unreacted groups on the surface were blocked by injection of 1 M ethanolamine (pH 8.0). Purified recombinant CnArg1 was N-terminally biotinylated and immobilised to a level of ~4000 RU onto the streptavidin surface at 25 °C in 20 mM HEPES, 200 mM NaCl, 5 mM MgCl$_2$ (pH 7.5) at a flow rate of 2 µL/min.
For analysis, compounds were prepared to 50 mM in 100% DMSO and diluted to the desired concentration in SPR running buffer; 20 mM HEPES (pH 7.5), 200 mM NaCl, 5 mM MgCl$_2$, 5% DMSO. Analysis was carried out using multi-cycle kinetics over a compound concentration range of 6.25–200 µM in running buffer at 10 °C, with an association time of 60 s and a dissociation time of 120 s. Data were reference subtracted, and a solvent correction applied. Analysis was carried out using Biacore T200 Evaluation Software and all data fit to a 1:1 Langmuir binding isotherm.

2.8. Synthesis of 2,6-Disubstituted Purine Analogues

2.8.1. General Experimental Procedure

All reagents were purchased and used without further purification. Silica gel was used for column chromatography purification. $^1$H NMR and $^{13}$C NMR spectra were collected on a Bruker Advance III Nanobay 400 MHz spectrometer ($^1$H at 400 MHz and $^{13}$C at 100 MHz). All spectra were processed using MestReNova 11.0 software. The chemical shifts of $^1$H and $^{13}$C are reported in parts per million (ppm) and were measured relative to the expected chemical shifts of the NMR solvents; CDCl$_3$, 7.26 (77.16 for $^{13}$C NMR) CD$_3$OD, 3.31 (49.00 for $^{13}$C NMR) and DMSO-$d_6$, 2.50 (39.52 for $^{13}$C NMR). The format used to report the spectra was as follows: chemical shift (multiplicity, coupling constant (if applicable), integration). Multiplicity was defined as: s = singlet, d = doublet, t = triplet, q = quartet, sd = singlet of doublets, dd = doublet of doublets, dt = doublet of triplets, tt = triplet of triplets and m = multiplet. Apparent splitting was abbreviated as app. and a broad resonance was abbreviated as br. Coupling constants were reported as $J$ in Hertz (Hz).

All analytical HPLC analyses were done on an Agilent 1260 Infinity Analytical HPLC coupled with a 1260 Degasser: G1322A, 1260 Binary Pump: G1312B, 1260 HiP ALS autosampler: G1367E, 1260 TCC: G1316A and 1260 DAD detector: G4212B. The column used was a Zorbax Eclipse Plus C18 Rapid Resolution 4.6 × 100 mm 3.5-micron. The sample injection volume was 2 µL which was run in 0.1% TFA in acetonitrile at a gradient of 5–100% over 10 min with a flow rate of 1 mL/min. Detection methods were with 214 nm and 254 nm.

All HRMS analyses were done on an Agilent 6224 TOF LC/MS Mass Spectrometer coupled to an Agilent 1290 Infinity (Agilent, Palo Alto, CA, USA). All data were acquired, and reference mass corrected via a dual-spray electrospray ionization (ESI) source. Each scan or data point on the Total Ion Chromatogram (TIC) is an average of 13,700 transients, producing a spectrum every second. Mass spectra were created by averaging the scans across each peak and background subtracted against the first 10 s of the TIC. Acquisition was performed using the Agilent Mass Hunter Fata Acquisition software version B.05.00 Build 5.0.5042.2 and analysis was performed using Mass Hunter Qualitative Analysis version B.05.00 Build 5.0.519.13.

2.8.2. General Procedure I for the First Nucleophilic Aromatic Substitution in the 6-Position (2a and 2b)

To a solution of 6-chloro-2-fluoropurine (1 mmol, 1.00 equiv.) in n-butanol (4 mL), was added N,N-diisopropylethylamine (1.41 equiv.). The mixture was stirred at room temperature for 5 min. To the mixture, was added an amine (1.02 equiv.). The mixture was warmed to 65 °C and stirred for 4 h. Then, the reaction mixture was concentrated in vacuo and to the residue, was added cold water. The precipitate was filtered, washed with cold water and purified.

2.8.3. General Procedure II for the Second Nucleophilic Aromatic Substitution in the 2-Position (9 to 29 (Excluding 14 and 17), 32, 35, 38 and 39)

To a solution of a N6-substituted-2-fluoro-9H-purin-6-amine (1 mmol, 1.00 equiv.) in n-butanol (4 mL), was added N,N-diisopropylethylamine (2.20 equiv.). The mixture was stirred at room temperature for 5 min. To the mixture, was added an amine (2.00 equiv.). The mixture was heated to reflux and stirred overnight (16 h). Then, the reaction mixture was concentrated in vacuo and purified.
2.8.4. General Procedure III for the Reductive Amination in the 2-Position (5a to 5c)

To a solution of 2-amino-6-chloropurine (1 mmol, 1.00 equiv.) in ethyl acetate (4 mL), was added a benzaldehyde (1.20 equiv.). The mixture was cooled to 0 °C and was added trifluoroacetic acid (2.24 equiv.) and sodium triacetoxyborohydride (1.50 equiv.). The reaction was warmed to room temperature and stirred overnight (16 h). The mixture was quenched with 10% aq. NaOH solution (20 mL) to pH ~8–9 and extracted with ethyl acetate (3 × 20 mL). The organic extracts were combined, washed with brine (50 mL) and dried over MgSO₄. Then, it was concentrated in vacuo and purified.

2.8.5. General Procedure IV for the Nucleophilic Aromatic Substitution in the 6-Position (14, 30, 31, 36 and 41 to 44)

To a solution of N₂-substituted-6-chloro-9H-purin-2-amine (1 mmol, 1.00 equiv.) in n-butanol (4 mL), was added an amine (1.50 equiv.) and triethylamine (1.00 equiv.). The reaction was heated to reflux and stirred for 5 h. Then, the reaction mixture was concentrated in vacuo and purified.

Additional synthetic methods and spectroscopic data for individual compounds is provided in the Supplementary Materials S1.

3. Results

3.1. Purification of IP₃-4K from C. neoformans, C. albicans and Human

IP₃-4K from C. neoformans (CnArg1) and C. albicans (Calpk2) and HsIPMK were expressed from pGEX-6P in E. coli as GST fusion proteins and purified in a two-step process involving glutathione-affinity chromatography, followed by GST cleavage by HRV 3C protease and size exclusion chromatography. SDS-PAGE indicated CnArg1 and Calpk2 have molecular weights close to the predicted values of 49 kDa and 40 kDa, respectively, and a purity of >95% (Figure 1A). SEC-MALLS was used to assess the oligomeric state and was consistent with both IP₃-4K enzymes being monomeric. The solution molecular weights of CnArg1 and Calpk2 were calculated as 52 kDa and 43 kDa, respectively (i.e., within 10% of the predicted monomer molecular weight) (Figure 1B). From SDS-PAGE, the molecular weight of HsIPMK was ~47 kDa (Figure 1A), in agreement with the predicted molecular weight of 47.2 kDa [40]. HsIPMK purity was ~60%. Reduced HsIPMK purity could be due to limited expression levels and contamination with bacterial heat shock proteins. HsIPMK was previously shown to be monomeric [21,22,40,41]. The purification yielded ~3.6 mg per litre of CnArg1, ~8.8 mg per litre of Calpk2 and ~0.3 mg per litre of HsIPMK proteins.

3.2. Establishing the Kinetic Properties of IP₃-4K

A luminescence assay was optimised from [14] to determine the kinetic properties of CnArg1 and Calpk2 using IP₃ as the substrate. For CnArg1 and Calpk2, the Kₘ was 300 ± 67 µM and 213 ± 49 µM, and the Vₘₐₓ was 12 ± 1.5 and 21 ± 3 µmol ATP/mg protein/min, respectively (Figure 2). Using the same assay conditions, HsIPMK had a lower Kₘ (128 ± 35 µM) compared to the fungal IP₃-4K enzymes and a lower Vₘₐₓ (0.6 ± 0.07 µmol ATP/mg protein/min) (Figure 2), consistent with a higher affinity for ATP. This compares to a previously determined Kₘ for ATP of 61 ± 6 µM when PIP2 was used as the substrate [22] and 10 µM when IP₄ was used as the substrate [31]. The Kₘ of rat IPMK for ATP was previously determined to be 64 µM when IP₃ was used as the substrate [36].
Figure 1. Assessment of purity, size and multimerization state of recombinant fungal IP_{3-4}K enzymes. IP_{3-4}K cDNA from C. neoformans (CnArg1), C. albicans (Calpk2) and human (HsIPMK) were cloned into the pGEX-6P expression vector and purified using a two-step procedure described in the methods. (A) SDS-PAGE was used to assess the size and purity of the recombinant fungal IP_{3-4}K enzymes. The theoretical molecular weights (MW) of the fungal enzymes, calculated from their amino acid sequences, are indicated next to the bands. (B) SEC-MALLS analysis suggested that CnArg1 and Calpk2 are monomeric with calculated molecular weights of 52 kDa and 43 kDa, respectively, in agreement with predicted values of 49 kDa and 40 kDa. The dotted lines represent the UV-profile of the eluted proteins, and the thick grey lines represent the SEC-MALLS-processed MW measurements.

Figure 2. Kinetic properties of recombinant fungal IP_{3-4}K enzymes and HsIPMK. Each enzyme was incubated with ATP (25–400 µM) and 200 µM of IP_{3} in a 50 µL reaction volume at room temperature for up to 10 min. Each data point was repeated at least twice. \( K_m \) and \( V_{max} \) values were obtained by fitting all data points to the Michaelis-Menten equation using GraphPad Prism 9 and are presented as the mean ± SEM. V: reaction velocity.
3.3. Optimizing the Enzyme Assay and Determining the IC_{50} of TNP

Next, we determined the inhibitory properties of TNP. TNP is an ATP-competitive inhibitor [34]. To bias the assay toward ATP-competitive inhibitors, the ATP concentration was reduced from 500 µM to 10 µM, which is a value lower than the K_{m} of all IP_{3,4}K enzymes (Figure 2). IP_{3} and enzyme concentrations were also optimised following the manufacturer’s instructions. Briefly, this involved measuring ATP consumption using a fixed saturated amount of kinase and varying the concentration of IP_{3} from 0 to 200 µM. The IP_{3} concentration that resulted in the largest change in luminescence was chosen as the optimal IP_{3} concentration. This optimal amount of IP_{3} was then used to test varying concentrations of the kinase ranging from 0 to 20 ng/µL. The amount of kinase that produced luminescence values in the linear range of the kinase titration curve was deemed to be the optimal kinase amount. The optimised concentrations of enzyme assay components are summarised in Table 2.

Table 2. Optimized concentrations of IP_{3} and enzyme used in the inhibition assay.

| Component | CnArg1 | CaIpK2 | HsIPMK |
|-----------|--------|--------|--------|
| ATP (µM)  | 10     | 10     | 10     |
| Enzyme (ng/µL) | 2.5    | 2.5    | 6      |
| IP_{3} (µM) | 50     | 25     | 25     |

Using the optimized assay conditions (Table 2), TNP was found to inhibit CnArg1 and HsIPMK with an IC_{50} of 21 ± 6 µM and 7 ± 0.5 µM, respectively (Figure 3). To our knowledge, this is the first report that TNP inhibits HsIPMK. Interestingly, TNP did not inhibit CaIpK2.

Figure 3. TNP inhibits CnArg1 and HsIPMK but not CaIpK2. Reactions were carried out at room temperature for 10 min using 10 µM ATP and the optimal amount of enzyme and IP_{3} as summarized in Table 2. ATP consumption was calculated from the luminescence reading and expressed as percentage enzyme activity according to the methods. The IC_{50} curves were generated by plotting % enzyme activity against the concentration of TNP. For CnArg1, the IC_{50} of 21 ± 6 µM (SEM) was calculated from 2 biological replicates, each performed in technical triplicate, error bar = SD. For HsIPMK, the IC_{50} of 7 ± 0.5 µM (SEM) was calculated from 3 technical replicates, error bar = SD. For CaIpK2, no inhibitory activity was found up to 50 µM (n = 1).

3.4. Synthesis of 2,6-Disubstituted Purine Analogues

TNP analogues were synthesized using multiple strategies that expedited the inclusion of substituents at the N2- and N6-positions of the purine scaffold (Tables 3–5). In addition, modification at N9 was included in examples 45 and 46 (Table 6). Note that several of these compounds were previously reported in studies of human IPKs as well as other enzyme targets [34,35,37,42,43].
Table 3. Summary of inhibitory properties resulting from chemical exploration at the N2 position of the TNP purine core following removal of the NO2 group at the N6 position (21 analogues). Only potent and soluble analogues with an IC50 < 40 µM for CnArg1 were tested for inhibitory properties against HsIPMK. ND = not determined.

For fixed N6-amine substitutions, 2-fluoro-6-chloro-9H-purine, 1 was subjected to consecutive nucleophilic aromatic substitutions (Scheme 1) [37,44,45]. While substitution of 1 occurs in the 6-position preferentially, giving 2 [46], bis-substitution was a common observation initially. Monitoring the temperature and length of the first nucleophilic aromatic substitution reaction gave improved outcomes. The second substitution at the 2-position yielded the target compounds, 3 but also proved to be challenging, with reactions requiring high reagent concentrations to proceed.
were tested for inhibitory activity against CaIPK2 (see supplementary Figure S1). Compound structures and their IC\textsubscript{50} values against CaIPK2, but slightly reduced potency against Ca\textsubscript{1}\textsubscript{Arg1}, had previously been described by \[34,37\] during their studies around IP3K and IP6K, respectively. They were poorly soluble in 5% DMSO.

Lastly, the impact of an alkyl group in the 9-position was explored. This was accomplished through alkylation of 7 using an alkyl halide to give 8 (Scheme 3).

Scheme 3. Synthesis of 8 via 7. i, R\textsubscript{3}X, 68–85%.

3.5. Assessment of the Inhibitory Properties of 2,6-Disubstituted Purine Analogues

Using the assay conditions established for TNP, all analogues were assessed for inhibition of \textit{Ca}\textsubscript{1}\textsubscript{Arg1}, \textit{HsIPMK} and \textit{Calpk2}. We found that most analogues inhibited \textit{Ca}\textsubscript{1}\textsubscript{Arg1} with IC\textsubscript{50} values ranging from 10–100 \textmu M (summarised in Tables 3–6), but none inhibited \textit{Calpk2} (see supplementary Figure S1). Compound structures and their IC\textsubscript{50} values against \textit{Ca}\textsubscript{1}\textsubscript{Arg1} and \textit{HsIPMK} are summarised in Tables 3–6. Only a selected number of analogues were tested for inhibitory activity against \textit{HsIPMK}, with a focus on those with similar or better potencies than TNP (i.e., those with an IC\textsubscript{50} less than 40 \textmu M). Note that the reduced potencies of some of these compounds could be due to poor solubility in water although this was not investigated further. Enzyme inhibition assays could not be performed on 11, 18 and 19 as they were poorly soluble in 5% DMSO.

We first identified that 9, which lacked the nitro group of TNP, had a similar potency to TNP against \textit{Ca}\textsubscript{1}\textsubscript{Arg1}, but slightly reduced potency against \textit{HsIPMK}. 9 had previously been described by \[34,37\] during their studies around IP3K and IP6K, respectively. They showed that the removal of the nitro group resulted in similar inhibition as TNP. Note that some structure activity relationship (SAR) against other human IPKs, IP3K and IP6K has been described before \[34\].
21 TNP analogues were created with modifications at the N2-position (see Table 3) encompassing a range of functional groups such as alternately substituted benzylamines (10–24), alternate aromatic moieties (25, 26), alkyl ethers and alcohols (27–29). In some cases, activity was abolished but overall, the inhibitory activity versus CnArg1 was only modestly affected compared to 9 (<2-fold difference). However, the selectivity of compounds for CnArg1 over HsIPMK was influenced by substitution. For example, 13 is a comparable inhibitor of CnArg1 to 9 but a much weaker inhibitor of HsIPMK.

Midway through this study, a research team at Johns Hopkins University published their strategy of first improving TNP solubility by replacing the N6-nitrobenzyl group with a methoxyethyl chain, before making further chemical modifications [37]. We employed the same strategy to explore the N2-position of the purine core, synthesizing a total of 11 analogues with the methoxyethyl chain at the N6-position (Table 4). It was reported that 30 had improved IP6K inhibition compared to TNP [37] but this was not observed with either CnArg1 or HsIPMK. Swapping benzylamine substitution at N2 gave a range of outcomes. Arylamine substitution as 37 and 40 was tolerated (IC50 of 17 ± 2 µM and 14 ± 0.5 µM, respectively).

Further variations at the N6-position were also considered (Table 5). One of these, 42, which had a 4-methyltetrahydropyran group, produced the most potent inhibition against CnArg1 with an IC50 of 10 ± 0.5 µM. Substitution in the 9-position was not tolerated in the two analogues, 45 and 46, which did not have any inhibitory activity for CnArg1 (Table 6).

### 3.6. Assessing Binding Affinities of TNP and Its Analogues

To complement the enzyme inhibition data, the binding affinities (K_D) of TNP analogues were determined for CnArg1 using surface plasmon resonance (SPR) and the results are summarised in Table 7 (see Figure S2 for representative SPR sensorgrams and dose–response curves). A K_D could not be determined for TNP and its closest analogue 9, due to poor behaviour on the SPR chip, which is most likely attributable to poor aqueous solubility. Chemical modification of TNP and 9 improved compound properties, allowing the binding affinities of 16 analogues to be determined. Apart from 37, these analogues bound to CnArg1, confirming a correlation between binding and inhibition. With the exception of 39 and 40, the analogues generally had comparable IC50 and K_D values.

**Table 7.** Summary to the binding affinities (K_D) of TNP and its analogues to CnArg1 as determined by surface plasmon resonance (SPR). Analogue binding to N-terminally biotinylated CnArg1 immobilised onto a streptavidin chip was assessed between 6.25–200 µM at 10 °C in 20 mM HEPES, 150 mM NaCl, pH 7.5. The IC50 and K_D values are presented as mean ± SEM (IC50—n ≥ 3 technical replicates; K_D—n ≥ 1). ND = not determined.

| Compound | IC50 (µM) | K_D (µM) |
|----------|-----------|----------|
| TNP      | 21 ± 6    | Poor solubility—ND |
| 9        | 28 ± 7    | Poor solubility—ND |
| 10       | 20 ± 1    | 17 ± 5   |
| 13       | 25 ± 1    | 13 ± 3   |
| 23       | 21 ± 1    | 22 ± 4   |
| 24       | 24 ± 1    | 16 ± 9   |
| 28       | 127 ± 32  | 321 ± 10 |
| 29       | 75 ± 9    | 155 ± 27 |
| 30       | 28 ± 1    | 70 ± 13  |
| 31       | 29 ± 3    | 35 ± 9   |
| 32       | 12 ± 0.5  | 38 ± 11  |
| 36       | 55 ± 6    | 74 ± 10  |
| 37       | 17 ± 2    | No binding |
| 39       | 22 ± 3    | 188 ± 9  |
| 40       | 13 ± 0.5  | 316 ± 31 |
| 41       | 24 ± 1    | 96 ± 10  |
| 42       | 10 ± 0.5  | 48 ± 7   |
| 43       | 27 ± 2    | 21 ± 9   |
3.7. Comparing the Selectivity of TNP and Its Analogues for CnArg1

Using the IC\textsubscript{50} data for TNP and the seventeen TNP analogues with the lowest IC\textsubscript{50} against CnArg1, the HsIPMK/CnArg1 IC\textsubscript{50} ratios were calculated (see last column in Tables 3–6) and plotted (Figure 4). Fourteen TNP analogues were found to be more selective for CnArg1 (ratio higher than 1). While unable to identify significantly more potent analogues of CnArg1 than TNP, the collected assessment of enzyme inhibitory activities did show that the relative selectivity over the human orthologue could be influenced by altered substitutions, with the selectivity ratios changing 20-fold in going from TNP (3-CF\textsubscript{3} substitution) to 13 (3-OCH\textsubscript{3} substitution) (Table 3).

![Figure 4. Selectivity of TNP and its analogues.](image)

**Figure 4. Selectivity of TNP and its analogues.** The selectivity of TNP and the seventeen analogues with the lowest IC\textsubscript{50} against CnArg1, for CnArg1 (blue dots) and HsIPMK (red dots), was determined by plotting the HsIPMK/CnArg1 IC\textsubscript{50} ratios.

4. Discussion

IP\textsubscript{3,4}K is critical for the virulence of *C. neoformans* and *C. albicans*. An IP\textsubscript{3,4}K (CnArg1) deletion mutant failed to either grow at 37 °C or establish an infection in a mouse model [14]. The mutant was also defective in producing a plethora of virulence-related phenotypes including capsule, melanin and phospholipase B, was more readily phagocytosed by blood-derived monocytes, had a cell wall defect and reduced metabolic flexibility and could not upregulate phosphate acquisition machinery in response to phosphate deprivation [13–16,49]. Attempts to delete both alleles of IP\textsubscript{3,4} kinase (Calpk2) in the diploid yeast, *C. albicans*, were unsuccessful, suggesting that IP\textsubscript{3,4}K is an essential protein. Using a knockdown approach, Calpk2 was shown to be essential for hyphal development, secretion of degradative enzymes and survival inside macrophages [17]. Targeting fungal IP\textsubscript{3,4}K is therefore a promising strategy for developing a novel class of antifungal drug. Fungal IP\textsubscript{3,4}K is also an attractive drug target due to the redundancy that exists in the analogous IP\textsubscript{3} to IP\textsubscript{5} conversion step in the human pathway.

Our SAR studies revealed that most TNP analogues inhibited CnArg1, but not Calpk2, and that many TNP analogues were more selective for CnArg1 over HsIPMK (summarised in Figure 4). This suggests that potential differences exist in the active site of each kinase. Like many IPK enzymes, the protein structures of CnArg1 and Calpk2 have not been experimentally determined. To investigate possible structural differences among the three IP\textsubscript{3,4}K proteins that could explain our results, we utilized the AlphaFold-predicted structures for CnArg1 (UniProt: J9W3G0) and Calpk2 (UniProt: Q59YE9) [50,51] and compared them to the published HsIPMK crystal structure consisting of amino acid residues 50 to 416 in a complex with ADP (PDB: 5W2H) [21,22]. The HsIPMK protein used to obtain the crystal structure had residues 263–377 deleted, which included a nuclear localisation signal.

Both the fungal IP\textsubscript{3,4} kinases share only a ~20% sequence homology with HsIPMK. However, an overlay of the AlphaFold models of CnArg1 and Calpk2 with HsIPMK (PDB: 5W2H) revealed a conserved catalytic core consisting of the three characteristic domains: an N-terminal \(\alpha + \beta\) domain (N-lobe), a C-terminal \(\alpha + \beta\) domain (C-lobe) and an inositol binding domain [21,22]. The N- and C-terminal domains each contain one anti-parallel beta sheet where ADP is sandwiched in between, making up the ATP binding site (Figure 5A, B). Seven out of twelve of the amino acids in the HsIPMK active site that interact with ATP are
conserved in CnArg1 and Calpk2 (Figure 5C,D) and represent Pro\textsuperscript{111}, Leu\textsuperscript{254}, Asp\textsuperscript{144}, Ile\textsuperscript{384}, Asp\textsuperscript{385} and Lys\textsuperscript{75} (Figure 5E). In HsIPMK, Leu\textsuperscript{254} and Ile\textsuperscript{384} form van der Waals interactions with each other and Asp\textsuperscript{144} forms a hydrogen bond with the ribose group of ADP. Asp\textsuperscript{385} interacts with the two magnesium ions, which in turn contact the two phosphate groups of ADP [21]. Ile\textsuperscript{384} and Asp\textsuperscript{385} are part of an Ile-Asp-Phe tripeptide, which is conserved in the IPK family and known to interact with a metal cofactor [11,21,52]. Lys\textsuperscript{75} forms a salt bridge with the alpha-phosphate of ADP [21].

Figure 5. Overlay of the ATP binding site of HsIPMK and the fungal IP\textsubscript{3-4}Ks to determine conservation of active site residues. ADP-bound HsIPMK structure (PDB:5W2H) showing the N-lobe in orange, C-lobe in yellow, hinge region in green and inositol binding domain (IP-domain) in blue is superimposed with the AlphaFold models of CnArg1 (cyan) (A) and Calpk2 (pink) (B). Surface representation (in grey) of the ATP-binding pocket of CnArg1 (C) and Calpk2 (D), with residues identical to those of HsIPMK in blue and residues non-identical to those of HsIPMK in yellow. Stick models depicting all residues involved in ATP binding (E) are depicted with CnArg1 in cyan, Calpk2 in pink and HsIPMK coloured green for carbon, blue for nitrogen and red for oxygen. Residues that differ among the three IP\textsubscript{3-4}K proteins being circled. For all panels, ADP is shown as stick representation with green for carbon, blue for nitrogen, red for oxygen and orange for phosphorus, and magnesium ions are depicted as violet spheres.
Differences between the fungal IP₃₄Ks and HsIPMK (Figure 5E, circled residues) are the replacement of the negatively charged Asp¹³² in HsIPMK with the polar asparagine in CnArg1 (Asn⁵⁰) and Calpk2 (Asn⁴⁰) and replacement of Glu¹³¹ in HsIPMK with Ala⁹⁹ in CnArg1 and Ser¹⁰¹ in Calpk2. In HsIPMK, Glu¹³¹ and hydrophobic Val¹³³ form hydrogen bonds with the N6 and N1 atoms of adenine, respectively. Residues within the ATP binding site that are unique to Calpk2 are Phe²⁸, which is replaced by valine in HsIPMK (Val⁷³) and CnArg1 (Val⁸⁵). In HsIPMK, Val⁷³ makes a van der Waals interaction with the adenine group of ADP [21]. The aromatic group on Phe²⁸ could potentially interfere with the binding of TNP and its analogues. Other differences are Ser¹⁰³ in Calpk2 replacing Val¹³³ (in HsIPMK) and CnArg1, and Cys²¹ in Calpk2 replacing Ile⁶⁵ (in HsIPMK) and Val²³ (in CnArg1). Ile⁶⁵ in HsIPMK makes van der Waals interaction with the adenine group of ADP.

Human IP6K2 was modelled using the Entamoeba histolytica (Eh) IP6KA crystal structure (PDB ID: 4O4D) and was subsequently used for SAR analysis with flavonoids [41] and TNP [35]. Similarly, differences in the fungal IP₃₄K active site residues can be further explored through molecular docking and/or via site-directed mutagenesis to identify residues responsible for the lack of inhibition observed for Calpk2 and to facilitate the design of a more potent inhibitor of CnArg1, which also inhibits Calpk2. This, TNP derivatives may become relevant to Calpk2 inhibition once the affinity of the compounds is increased to give IC₅₀ in the nanomolar range.

5. Conclusions

In summary, we have demonstrated that TNP and a series of analogues derived from it, inhibit purified, tag-free IP₃₄K produced by the human fungal pathogen, C. neoformans. We also show that the relative selectivity of TNP and its analogues over the human orthologue can be influenced 20-fold by making substitutions at the N2 position of the purine. Recently released AlphaFold protein models of fungal pathogen IP₃₄Ks have also revealed amino acid differences in the human and fungal ATP binding site, which are being used in combination with the assays developed to guide ongoing SAR studies aimed at improving the potency and selectivity of the TNP analogues for the fungal enzyme targets, and testing new IPK inhibitor scaffolds.

Supplementary Materials: The following supporting information can be downloaded at: https://www.mdpi.com/article/10.3390/biom12101526/s1, Data S1: Synthetic methods and spectroscopic data for individual compounds. Figure S1: TNP and its analogues did not inhibit Calpk2 when tested at concentrations up to 50 µM. Figure S2: Surface plasmon resonance (SPR) sensorgrams and dose-response curves of compounds 39 and 41 are shown as representative data. The Kᵦ values in Table 7 were obtained using steady-state affinity.

Author Contributions: J.T.D. and P.E.T. conceptualized the project. D.D., D.T., L.W.-W., S.L., M.T. and C.D. developed the methodology and performed the investigation, formal analysis and validation. D.D., D.T., J.T.D. and P.E.T. wrote and reviewed the original manuscript draft. All authors reviewed and edited subsequent manuscript drafts. J.T.D., P.E.T., L.W.-W. and C.D. supervised project members. J.T.D. and P.E.T. administered the project. J.T.D., P.E.T., J.P.M., T.C.S. and J.M.M. were involved in funding acquisition. All authors have read and agreed to the published version of the manuscript.

Funding: This project was supported by seed grants from the University of Sydney Drug Discovery Institute and the Sydney Institute for Infectious Diseases, an Industry PhD scholarship from NSW Health and the University of Sydney and project grants to J.T. Djordjevic from the National Health and Medical Research Council (NHMRC) of Australia (APP1183939, APP1058779). Daniel Truong is a recipient of an RTP scholarship from the Australian Government.

Institutional Review Board Statement: Not applicable.

Informed Consent Statement: Not applicable.

Data Availability Statement: Not applicable.
Acknowledgments: We thank the Westmead Scientific Platforms, which is supported by the Westmead Institute for Medical Research, the Cancer Institute New South Wales and the NHMRC, for providing access to instrumentation to perform the enzyme assays. This research was facilitated by access to Sydney Analytical, a core research facility at the University of Sydney.

Conflicts of Interest: The authors declare no conflict of interest.
