Axiomatization of Finite Algebras

Jochen Burghardt

GMD FIRST, Kekulestraße 7, D–12489 Berlin, jochen@first.gmd.de

Abstract. We show that the set of all formulas in \( n \) variables valid in a finite class \( A \) of finite algebras is always a regular tree language, and compute a finite axiom set for \( A \). We give a rational reconstruction of Barzdins’ liquid flow algorithm [BB91]. We show a sufficient condition for the existence of a class \( A \) of prototype algebras for a given theory \( \Theta \). Such a set allows us to prove \( \Theta \models \varphi \) simply by testing whether \( \varphi \) holds in \( A \).

1 Introduction

Abstraction is a key issue in artificial intelligence. In the setting of mathematical logic and model theory, it is concerned with the relation between concrete algebras and abstract statements about them in a formal language. For purely equational theories, the well-known construction of an initial model (e.g. [DJ90]) allows one to compute a kind of prototypical algebra for a given theory. In the other direction (i.e. from concrete algebras to theories), however, no computable procedures are yet known. While it is trivial to check whether a given formula is valid in a given finite algebra, it is not clear how to find a finite description of all valid formulas.

In 1991, Barzdin and Barzdin [BB91] proposed their liquid–flow algorithm which takes an incompletely given finite algebra and acquires hypotheses about what are probable axioms. We give a rational reconstruction of this work that is based on well-known algorithms on regular tree grammars. We give a correspondence between Barzdins’ notions and grammar notions, showing that the liquid–flow algorithm in fact amounts to a combination of classical grammar algorithms (Thm. 10).

The correspondence leads to synergies in both directions: Barzdins’ approach could be extended somewhat, and a classical algorithm seems to be improvable in its time complexity using the liquid–flow technique.

Next, we focus on a completely given algebra and show how to compute finite descriptions of the set of all variable-bounded formulas valid in it. This set is described by a grammar (Thm. 11) and by an axiom set (Thm. 13).

We relate our work to Birkhoff’s variety theorem [MT92], which states that a class \( A \) of algebras can be characterized by equational axioms only up to its variety closure \( \text{vc}(A) \). If \( A \) is a finite class of finite algebras such that \( \text{vc}(A) \) is is finitely axiomatizable at all, we can compute an equational axiom set for it (Cor. 15).
As an application in the field of automated theorem proving, we give a sufficient criterion for establishing whether a class \( \mathcal{A} \) of algebras is a prototype class for a given theory \( \Theta \) (Cor. 17). If the criterion applies, the validity of any formula \( \varphi \) in \( n \) variables can be decided quickly and simply by merely testing \( \varphi \) in \( \mathcal{A} \), avoiding the search space of usual theorem proving procedures: \( \Theta \models \varphi \) if and only if \( \varphi \) is satisfied in every \( \mathcal{A} \in \mathcal{A} \).

Section 2 recalls some formal definitions. In order to make this paper self-contained, we refer well-known results on regular tree grammars that are used in the sequel. Section 3 first gives a rational reconstruction of Barzdins’ liquid flow contained, we refer well-known results on regular tree grammars that are used in...
When encoding predicates and junctors using a sort \( \text{Bool} \), in order to obtain an appropriate semantics\(^1\) it is necessary and sufficient to fix the interpretation of the sort \( \text{Bool} \) accordingly for every algebra under consideration. Therefor, we define below the notion of an admitted algebra, and let the definition of \( \text{sat} \), \( \models \), etc. depend on it.

We tacitly assume that,

- when we consider only equations, each algebra is admitted, while,
- when we consider arbitrary predicates, junctors and a sort \( \text{Bool} \), only algebras with an appropriate interpretation of \( \text{Bool} \) are admitted.

**Definition 4.** [Admitted algebras] Let a signature \( \Sigma \) be given. Let \( S_{\text{fix}} \subseteq S \) be a set of sorts; and let \( \Sigma_{\text{fix}} \) be the set of all \( f \in \Sigma \) that have all argument and result sorts in \( S_{\text{fix}} \). Let a fixed \( \Sigma_{\text{fix}} \)-algebra \( A_{\text{fix}} \) be given; we denote its domain sets by \( A_{\text{fix},S} \).

We say that a \( \Sigma \)-algebra \( A \) is admitted if \( A_S = A_{\text{fix},S} \) for each \( S \in S_{\text{fix}} \) and \( t_1 =_A t_2 \Leftrightarrow t_1 =_{A_{\text{fix}}} t_2 \) for all \( t_1, t_2 \in T_{\{1\},S}(\Sigma_A) \) and \( S \in S_{\text{fix}} \). \( \Box \)

**Definition 5.** [Validity] For an admitted \( \Sigma \)-algebra \( A \) and a formula \( \varphi \), we write \( A \text{ sat } \varphi \) if \( \varphi \) is valid in \( A \), where equality symbols \( (=) \) in \( \varphi \) are interpreted as identity relations on \( A_S \), rather than by an arbitrary congruence on it. For a class of admitted \( \Sigma \)-algebras \( A \), and a theory \( \Theta \), we similarly write \( A \text{ sat } \Theta \), \( A \text{ sat } \varphi \), \( A \text{ sat } \Theta \), and \( A \text{ sat } \Theta \). Define \( \Theta_1 \models \Theta_2 \) if \( A \text{ sat } \Theta_1 \) implies \( A \text{ sat } \Theta_2 \) for each admitted \( \Sigma \)-algebra \( A \).

If we choose \( S_{\text{fix}} := \{\} \), each algebra is admitted. Choosing \( S_{\text{fix}} := \{\text{Bool}\} \), 
\( \Sigma_{\text{fix}} := \{(\neg), (\land), (\lor), (\to), (\leftrightarrow)\} \), and \( A_{\text{fix}} \) as the two–element Boolean algebra, we prescribe the interpretation of \( \text{Bool} \) for each admitted algebra. \( \Box \)

**Definition 6.** [Complete theorem sets] For a \( \Sigma \)-algebra \( A \), a tuple \( x \) of variables as in Def. 3, define \( \mathcal{T}_A(x) := \{Q : t_1 =_S t_2 \mid Q \in \mathcal{Q}(x), S \in S, t_1, t_2 \in T_{\{x\},S}(\Sigma), A \text{ sat } (Q : t_1 =_S t_2)\} \)

as the set of all formulas over \( \Sigma \) and \( x \) that are valid in \( A \). The elements of \( \mathcal{T}_A(x) \) can be considered as terms over the extended signature

\[ \Sigma \cup \{(=) \mid S \in S\} \cup \{(Q) \mid Q \in \mathcal{Q}(x)\}. \]

For a class \( A \) of \( \Sigma \)-algebras, define \( \mathcal{T}_A := \bigcap_{A \in A} \mathcal{T}_A(x) \).

\( \Box \)

**Example 7.** The algebra \( A_2 \), defined by \( A_{\text{Nat}} := \{0, 1\} \) and \( E_A := \{0+0 = 0, 0+1 = 1, 1+0 = 1, 1+1 = 0\} \), is a \( \Sigma \)-algebra for \( \Sigma = \{0, (+)\} \). The set \( \mathcal{T}_{A}(x,y)(A_2) \) contains the formula \( \forall x \exists y : x + y = 0 \), but not \( \forall x \exists y : x + y = 1 \), since \( 1 \notin \Sigma \). \( \Box \)

\(^1\) If in some algebra \( A \) we had \( A_{\text{Bool}} = \{a\} \) and \( \text{true} = a, \text{false} = a \in E_A \), any formula \( \varphi \) was valid in \( A \).
**Definition 8.** [Regular tree grammar] A regular tree grammar \( G \) consists of rules \( N := f_1(N_{i_1}, \ldots, N_{i_n}) \mid \ldots \mid f_m(N_{m_1}, \ldots, N_{m_m}) \) or \( N := N_1 \mid \ldots \mid N_m \) where \( N, N_i, N_{ij} \) are nonterminal symbols and \( f_i \in \Sigma \). Note that \( n_i \) may be also 0. Each \( f_i(N_{i_1}, \ldots, N_{i_n}) \) or \( N_i \) is called an alternative. \( N, N_i, N_{ij} \) are assigned a sort each that have to fit with each other and with \( f_i \).

The size \( |G| \) of \( G \) is its total number of alternatives. We denote the set of nonterminals of \( G \) by \( N \). The language produced by a nonterminal \( N \) of \( G \) is denoted by \( \mathcal{L}_G(N) \), it is a set of ground terms over \( \Sigma \); if \( N \) is the start symbol of \( G \), we also write \( \mathcal{L}(G) \). \( G \) is called deterministic if no different rules have identical alternatives.

Define the generalized height \( h_g(t) \) of a ground term \( t \) by

\[
  h_g(f(t_1, \ldots, t_n)) = \max\{h_g(t_1), \ldots, h_g(t_n)\} + h_g(f),
\]

where \( \max\{\} = 0 \), and \( h_g(f) \in \mathbb{N} \) may be defined arbitrarily. For a nonterminal \( N \) of a grammar \( G \), define \( h_g(N) \) as the minimal height of any term in \( \mathcal{L}_G(N) \), it is \( \infty \) if \( \mathcal{L}_G(N) \) is empty.

**Theorem 9.** [Properties of regular tree grammars]

1. Incorporating [McA92, Sect.6]
   Given a finite many–sorted \( \Sigma \)–algebra \( A \), a grammar \( G = \text{incorporate}(A) \) of size \( |E_A| \) can be computed in time \( O(|E_A|) \) such that
   \[
   \forall S \in \mathcal{S}, a \in A_S \exists N_a \in N : \mathcal{L}_G(N_a) = \{t \in T_1(\Sigma_A) \mid t =_A a\}.
   \]

2. Externizing [McA92, Sect.3]
   Given a deterministic grammar \( G \), a set \( E \) of \( |G| \) ground equations can be computed in time \( O(|G|) \) such that for all ground terms \( t_1, t_2 \):
   \[
   t_1 =_E t_2 \iff \exists N \in N : t_1, t_2 \in \mathcal{L}_G(N),
   \]

   where \( (=_E) \) denotes the congruence induced by \( E \).

3. Lifting [CDG+99, Thm.7 in Sect.1.4]
   Given a grammar \( G \) and a ground substitution \( \sigma \), a grammar \( G' = \text{lift}(G, \sigma) \) of size \( |G| + |N| \cdot |\text{dom}\sigma| \) can be computed in time \( O(|G'|) \) such that
   \[
   \forall N \in N \exists N' \in N' : \mathcal{L}_G(N') = \{t \in T_{\text{dom}\sigma} \mid \sigma t \in \mathcal{L}_G(N)\},
   \]

   where \( N \) and \( N' \) is the set of nonterminals of \( G \) and \( G' \), respectively. Note that the signature gets extended by \( \text{dom}\sigma \); these variables are treated as constants in \( G' \).

4. Intersection [CDG+99, Sect.1.3]
   Given \( n \) grammars \( G_1, \ldots, G_n \), a grammar \( G = \text{intersect}(G_1, \ldots, G_n) \) of size \( |G_1| \cdot \ldots \cdot |G_n| \) can be computed in time \( O(|G|) \) such that for each
   \[
   \forall N_{i_1} \in N_{i_1}, \ldots, N_{i_n} \in N \exists n_{i_1}, \ldots, n_{i_n} \in N : \mathcal{L}_G(N) = \bigcap_{j=1}^{n} \mathcal{L}_{G_j}(N_{i_j}).
   \]
5. Restriction [special case of 4]
Interession of one grammar $G_1$ with a term universe $T_{V,S}(\Sigma)$, such that
\[ \forall N_1 \in N_1 \exists N \in N : L_G(N) = L_{G_1}(N_1) \cap T_{V,S}(\Sigma) \]
can be done in time $O(|G_1|)$ by removing all symbols not in $\Sigma$.

6. Union [CDG+99, Sect.1.3]
Given $n$ grammars $G_1, \ldots, G_n$, a grammar $G = \text{unite}(G_1, \ldots, G_n)$ of size $n + |G_1| + \ldots + |G_n|$ can be computed in time $O(n)$ such that
\[ L(G) = \bigcup_{i=1}^n L(G_i) \]
by adding one rule.

7. Composition [Trivial]
Given an $n$-ary function symbol $f$, a grammar $G$, and nonterminals $N_1, \ldots, N_n$, a grammar $G' = \text{tag}(G, f(N_1, \ldots, N_n))$ of size $|G| + 1$ can be computed in time $O(1)$ such that
\[ L_{G'}(N) = \{ f(t_1, \ldots, t_n) \mid \bigwedge_{i=1}^n t_i \in L_G(N_i) \} \]
for a certain nonterminal $N$, by adding one rule.

8. Weight computation [AM91, Sect.4]
Given a grammar $G$, the heights $hg(N)$ can be computed for all nonterminals $N \in N$ simultaneously in time $O(|N|^2)$.

9. Language enumeration [BH96, Fig.21]
Given a grammar $G$ and the heights of all nonterminals, the elements of $L_G(N)$ can be enumerated in order of increasing height in time linear in the sum of their sizes by a simple Prolog program.

\[ \square \]

3 Equational Theories of Finite Algebras

First, we give a rational reconstruction of the liquid flow algorithm of Barzdin and Barzdin [BB91]. They use labeled graphs to compute an axiom set from an incompletely given finite algebra. Their approach can be reformulated in terms of regular tree languages using the correspondence of notions shown in Fig. 1. Our following theorem corresponds to their main result, Thm. 2. It is in fact a slight extension, as it allows for sorts and for substitutions that map several variables to the same value.

On the other hand, the liquid flow algorithm turns out to be an improvement of the weight computation algorithm from Thm. 9.8. Both are fixpoint algorithms, and identical except for minor, but important, modifications. The algorithm from Thm. 9.8 has a complexity of $O(|N|^2)$, while Barzdins’ algorithm runs in $O(|N|)$, exploiting the fact that always $hg(f) \leq 1$ and therefore the first value $< \infty$ assigned to some $hg(N)$ must be its final one already. Since
in each cycle at least one \( N \) must change its assigned \( hg \) value\(^2\), by an appropriate incremental technique (water front), linear complexity can be achieved. A formal complexity proof of this improved grammar fixpoint algorithm, extended to somewhat more general weight definitions, shall appear in [Bur02].

**Theorem 10.** [Reconstruction of Barzdin] Given a \( \Sigma \)-algebra \( A \), domain elements \( b_1, \ldots, b_n \in A_{S_0}, a_{11}, \ldots, a_{n1} \in A_{S_1}, \ldots, a_{1k}, \ldots, a_{nk} \in A_{S_k} \), and defining \( \sigma_i = \{ x_1 \mapsto a_{i1}, \ldots, x_k \mapsto a_{ik} \} \) for \( i = 1, \ldots, n \) and \( V := \{ x_1, \ldots, x_k \} \), the set of terms \( T = \{ t \in T_V, S_0(\Sigma) \mid \bigwedge_{i=1}^n \sigma_i t =_A b_i \} \) is a regular tree language. A grammar for it can be computed in time \( O(|E_A| n) \). After computing nonterminal weights in time \( O(|E_A| 2^n) \), the language elements can be enumerated in order of increasing height in linear time.

**Proof.** Using the notions of Thm. 9, let \( G_0 := \text{incorporate}(A) \), and \( G_i := \text{lift}(G_0, \sigma_i) \) for \( i = 1, \ldots, n \). We have

\[
L_{G_i}(N_a) = \{ t \in T_V(\Sigma_A) \mid \sigma_i t =_A a \}
\]

Let \( G := \text{intersect}(G_1, \ldots, G_n, T_V(\Sigma)) \), then

\[
L_G(N_{a_1, \ldots, a_n}) = \{ t \in T_V(\Sigma) \mid \bigwedge_{i=1}^n \sigma_i t =_A a_i \}
\]

Hence \( T = L_G(N_{b_1, \ldots, b_n}) \). Note that \( G \) itself does not depend on \( b_1, \ldots, b_n \).

Compute the height of all nonterminals of \( G \) using Thm. 9.8, using \( hg(x_i) := 0 \) for \( x_i \in V \) and \( hg(f) := 1 \) for \( f \in \Sigma \). Use Thm. 9.9 to enumerate the terms of \( L_G(N_{b_1, \ldots, b_n}) \).

Barzdin and Barzdin allow to specify an algebra incompletely, since their main goal is to acquire hypotheses about what are probable axioms.

We now investigate the special case that the substitutions \( \sigma_1, \ldots, \sigma_n \) in Thm. 10 describe all possible assignments of algebra domain elements to the variables \( x_1, \ldots, x_k \). This way, we obtain certainty about the computed axioms – they are guaranteed to be valid in the given algebra.

**Theorem 11.** [Computing complete theorem sets] Let \( x = (x_1, \ldots, x_k) \) be a \( k \)-tuple of variables, \( A \) be a finite \( \Sigma \)-algebra and \( \mathcal{A} \) a finite class of finite \( \Sigma \)-algebras, then \( \mathcal{TH}_x(A) \) and \( \mathcal{TH}_x(\mathcal{A}) \) are regular tree languages.

**Proof (sketch).** Define \( A_x := A_{\text{sort}(x_1)} \times \cdots \times A_{\text{sort}(x_k)} \). For each \( a \in A_x \), let \( \sigma_a := \{ x_1 \mapsto a_{11}, \ldots, x_k \mapsto a_{1k} \} \). Let \( G = \text{incorporate}(A) \) and \( G_a = \text{intersect}(\text{lift}(G, \sigma_a), T_x(\Sigma)) \) for \( a \in A_x \). For \( S \in \mathcal{S} \) and \( a \in A_S \), let \( G_{a,S} = \text{tag}(G_a, N_a =_S N_a) \), where \( (=_S) \) is a new binary infix function symbol. Let \( G_a = \text{unite}(\{ G_{a,S} \mid S \in \mathcal{S}, a \in A_S \}) \) for each \( a \in A_x \). We have

\[
L(G'_a) = \{ t_1 =_S t_2 \mid S \in \mathcal{S}, t_1, t_2 \in T_{x,S}(\Sigma), \sigma_a t_1 =_A \sigma_a t_2 \}.
\]

- Minimal $\alpha$–term of domain node $d$ term $t \in \mathcal{L}(N_d)$ of minimal height
- Minimal $\alpha$–term of functional node term $t \in \mathcal{L}(f(N_{a_1}, \ldots, N_{a_n}))$ of minimal height
- Theorem 1 Theorem 10
- Theorem 2 Theorem 10 for $n = 1$

**Fig. 1.** Correspondence of notions between [BB91] and regular tree grammars

Now, for each $Q \in \mathcal{Q}(x)$, apply set operations corresponding to $Q$ to the $G_a$; e.g. if $k = 2$ and $Q = (\forall x_1 \exists x_2)$, let

$$G_Q = \text{intersect}(\{\text{unite}(\{G_{a_1,a_2} \mid a_2 \in A_{\text{sort}(a_2)}\}) \mid a_1 \in A_{\text{sort}(a_1)}\}).$$

In general, we get

$$\mathcal{L}(G_Q) = \{t_1 = S t_2 \mid S \in S, \ t_1,t_2 \in \tau_{x,S}(\Sigma), \ A \text{ sat } (Q : t_1 = t_2)\}.$$  

For each $Q \in \mathcal{Q}(x)$, let $G_Q' = \text{tag}(G_Q, Q : G_Q)$, where $(Q : \cdot)$ is a new unary prefix function symbol. Let $G' = \text{unite}(\{G_Q' \mid Q \in \mathcal{Q}(x)\})$, then $\tau_{H_x}(A) = \mathcal{L}(G')$. From this, we immediately get a grammar for $\tau_{H_x}(A)$ by Thm. 9.4. □

**Example 12.** Let us compute $\tau_{H_x}(A_2)$ for the algebra $A_2$ from Exm. 7 and $x = \langle x, y \rangle$. We have the substitutions $\sigma_{00}, \sigma_{01}, \sigma_{10}, \sigma_{11}$ and use the naming convention

$$\mathcal{L}(N_{ijkl}) = \mathcal{L}(G_{00,i}) \cap \mathcal{L}(G_{01,j}) \cap \mathcal{L}(G_{10,k}) \cap \mathcal{L}(G_{11,l}),$$

e.g. $\mathcal{L}(N_{0011}) = \{t \in \tau_x(\Sigma) \mid A_2 \text{ sat } (\sigma_{00}t = \sigma_{01}t = 0 \land \sigma_{10}t = \sigma_{11}t = 1)\}$. A “*” may serve as don’t care symbol, e.g. $\mathcal{L}(N_{0kk}) = \mathcal{L}(G_{00,i}) \cap \mathcal{L}(G_{10,k})$.

From Thm. 11, after incorporating, lifting, and restricting, we obtain e.g. $G_{00}$, with nonterminals $N_{0**}$ and $N_{1**}$. As $\mathcal{L}(N_{1**})$ turns out to be empty, we simply have

$$N_{0**} ::= 0 \mid x \mid y \mid N_{0**} + N_{0**}.$$
\[ N_{0000} ::= 0 \mid N_{0000} + N_{0000} \mid N_{0011} + N_{0011} \mid N_{0101} + N_{0101} \mid N_{0110} + N_{0110} \]
\[ N_{0011} ::= x \mid N_{0000} + N_{0011} \mid N_{0011} + N_{0000} \mid N_{0101} + N_{0110} \mid N_{0101} + N_{0101} \]
\[ N_{0101} ::= y \mid N_{0000} + N_{0101} \mid N_{0011} + N_{0101} \mid N_{0101} + N_{0000} \mid N_{0101} + N_{0111} \]
\[ N_{0111} ::= N_{0000} + N_{0111} \mid N_{0101} + N_{0111} \mid N_{0110} + N_{0011} \mid N_{0110} + N_{0000} \]
\[ N_{0+0} ::= N_{0000} \mid N_{0001} \mid N_{0100} \mid N_{0101} \]
\[ N_{0+1} ::= \ldots \]
\[ N_{0\forall} ::= N_{0000} = N_{0000} \mid N_{0001} = N_{0001} \mid N_{0010} = N_{0010} \mid N_{0011} = N_{0011} \]
\[ N_{0\exists} ::= N_{0+0} = N_{0+0} \mid N_{0+1} = N_{0+1} \mid N_{0+0} = N_{0+0} \mid N_{0+1} = N_{0+1} \]
\[ N_{1\forall} ::= N_{0000} = N_{0000} \mid N_{0101} = N_{0101} \mid N_{0110} = N_{0110} \]
\[ N_{1\exists} ::= N_{0+0} = N_{0+0} \mid N_{0+1} = N_{0+1} \mid N_{0+0} = N_{0+0} \mid N_{0+1} = N_{0+1} \]
\[ N ::= \forall x \forall y : N_{0\forall} \mid \forall x \exists y : N_{0\exists} \mid \exists x \forall y : N_{1\forall} \mid \exists x \exists y : N_{1\exists} \]

Fig. 2. Grammar \( G' \) for \( TH_x(A) \) in Exm. 12

Fig. 3. Example derivations from \( G' \) in Exm. 12

\[ \forall x \forall y : N_{0\forall} \]
\[ \forall x \forall y : \frac{N_{0101}}{N_{0110}} = N_{0110} \]
\[ \forall x \forall y : \frac{N_{0011} + N_{0101}}{y + x} = N_{0101} + N_{0011} \]
\[ \forall x \forall y : x + y = y + x \]

\[ \forall x \exists y : \frac{N_{0+0}}{N_{0+0}} = N_{0+0} \]
\[ \forall x \exists y : \frac{N_{0110}}{N_{0110}} = N_{0000} \]
\[ \forall x \exists y : \frac{N_{0011} + N_{0101}}{N_{0101} + N_{0111}} = 0 \]
\[ \forall x \exists y : \frac{x + y}{x + y} = 0 \]
We obtain $G'_0$ by just adding the rule $N := (N_0 = N_0)$. To compute $G_{\forall\forall}$, we build all intersections $N_{ijkl}$ without "*"; only four of them turn out to be nonempty, their rules are shown in Fig. 2. The grammar $G_{\forall\forall}$ consists of these rules and an additional one for its start symbol $N_{\forall\forall}$. The grammars $G_{\forall\exists}$, $G_{\exists\forall}$, and $G_{\exists\exists}$ have similar starting rules, which use only nonterminals $N_{ijkl}$ containing a "*". Since the rules for the latter are trivial, only the one for $N_{0000}$ is shown. Finally, the grammar $G'$ for $TH_x(A_2)$ consists of all these rules and an additional one for its start symbol $N$. Figure 3 show some example derivations. 

**Theorem 13.** [Computing complete axiom sets] The sets $TH_x(A)$ and $TH_x(A)$ obtained from Thm. 11 can be represented as the deductive closure of a finite set of formulas, called $AX\chi_x(A)$ and $AX\chi_x(A)$, respectively. We have:

\[
\forall t_1, t_2 \in T_x(\Sigma) : A sat \ t_1 = t_2 \Leftrightarrow AX\chi_x(A) \models t_1 = t_2 \quad \text{and} \quad \forall t_1, t_2 \in T_x(\Sigma) : A sat \ t_1 = t_2 \Leftrightarrow AX\chi_x(A) \models t_1 = t_2.
\]

**Proof (sketch).** First, we consider the purely universal formulas in $TH_x(A)$. Using the notions of Thm. 11, the grammar $G_{\forall\forall}$ is deterministic since no union operations were involved in its construction. Using Thm. 9.2, we get a finite set $E_{\forall\forall}$ of equations, each of which we compose with the appropriate universal quantifier prefix $\forall x_1 \ldots \forall x_k :$. The resulting formula set $E'_{\forall\forall}$ implies any purely universal equation valid in $A$. By construction of $E_{\forall\forall}$, it can reduce each term $t$ in any quantified equation in $TH_x(A)$ to a unique normal form. Let $NF$ denote the set of all those normal forms; it is finite since $|N|$ is finite.

Next, for any quantifier prefix $Q$ containing some "$\exists$", let

\[E'_Q := \{ Q : t_{1n} = t_{2n} | t_{1n}, t_{2n} \in NF, (t_{1n} = t_{2n}) \in L(G_Q), t_{1n} \neq t_{2n} \}.\]

Any formula $Q : t_1 = t_2$ in $L(G'_Q)$ can then be deduced from $\forall \ldots \forall : t_1 = t_{1n}$ and $\forall \ldots \forall : t_2 = t_{2n}$ in $E'_{\forall\forall}$ and $Q : t_{1n} = t_{2n}$ in $E'_Q$, where $t_{1n}$ and $t_{2n}$ are the normal forms of $t_1$ and $t_2$, respectively.

Finally, let $AX\chi_x(A) = \bigcup_{Q \in Q(x)} E'_Q$. The proof for $AX\chi_x(A)$ is similar. 

Observe that the variables in $x$ are introduced as constants into the grammars, hence $E_{\forall\forall}$ in the above proof is a set of ground equations. A closer look at the algorithm referred by Thm. 9.2 reveals that it generates in fact a Noetherian ground-rewriting system assigning unique normal forms. Anyway, no proper instance of any formula from $AX\chi_x(A)$ is needed to derive any one in $TH_x(A)$.

By permitting proper instantiations, we may delete formulas that are instances of others, thus reducing their total number significantly. To find such subsumed formulas, an appropriate indexing technique may be used, see e.g. [Gra94].

**Example 14.** Continuing Exm. 12, and referring to the notions the proof of of Thm. 13, we obtain the set $E_{\forall\forall}$ shown at the top of Fig. 4, where we chose the normal form of $N_{0000}, N_{0011}, N_{0101}$, and $N_{0110}$ as 0, $x, y$, and $x+y$, respectively. 

---

3 The algorithm of Thm. 9.2 can easily be modified to work with arbitrary chosen normal forms instead of external constants.
\[ \forall : \quad N_{0000} : \quad \begin{array}{c} 0 = 0 + 0 = x + x = y + y = (x+y) + (x+y) \\ N_{0011} : \quad \begin{array}{c} x = 0 + x = x + 0 = y + (x+y) = (x+y) + y \\ N_{0101} : \quad \begin{array}{c} y = 0 + y = x + (x+y) = y + 0 = (x+y) + x \\ N_{0110} : \quad \begin{array}{c} x+y = 0 + (x+y) = y + x = (x+y) + 0 \end{array} \end{array} \end{array} \]

\[ \exists : \quad N_{000*} : \quad \begin{array}{c} 0 = y \\ N_{00*0} : \quad \begin{array}{c} 0 = x+y \\ N_{001*} : \quad \begin{array}{c} x = x+y \\ N_{010*} : \quad \begin{array}{c} 0 = x \\ N_{011*} : \quad \begin{array}{c} y = x+y \\ N_{*00*} : \quad \begin{array}{c} 0 = y \\ N_{*01*} : \quad \begin{array}{c} x = x+y \\ N_{*0*0} : \quad \begin{array}{c} 0 = x+y \\ N_{*0*1} : \quad \begin{array}{c} x = y \end{array} \end{array} \end{array} \end{array} \end{array} \end{array} \end{array} \]

Fig. 4. Axioms \( \mathcal{AX}_A(A) \) in Exm. 14

which are each of minimal size. From each rule alternative in Fig. 2, we get one equation that is universally valid in \( A \). The equations between marked terms remain nontrivial if instantiations are allowed.

For each of the \( N_{ijkl} \) with a \( "*" \), we check which of the above 4 normal forms are member of \( \mathcal{L}(N_{ijkl}) \). This can be decided quickly by matching the index; e.g. \( N_{00*0} \) contains 0 and \( y \) since \( 0*0* \) matches with \( 0000 \) and \( 0101 \). Each pair of normal forms in the same \( \mathcal{L}(N_{ijkl}) \) gives rise to an equation, shown at the bottom of Fig. 4. Note that equations between terms of different \( N_{ijkl} \) are neither in \( \mathcal{T}_H(A) \) nor in \( \mathcal{AX}_A(A) \). For example, “crossing” \( N_{00*0} \) and \( N_{00*0} \) yields the forbidden formula \( \forall x \exists y : y = x + y \) which does not hold in \( A \).

After removing all redundancies\(^4\), we get

\[ \{ \quad \forall x : 0 = x+x, \quad \forall x \forall y : x+y = y + x, \quad \forall x \exists y : 0 = x+y, \quad \forall x : x = x+0, \quad \forall x \forall y : x = (x+y) + y \quad \} \]

as a set of formulas implying every closed formula over \( \{ x, y, 0, (+), (=) \} \) that is valid in \( A \). Note that the associativity law is not implied, since it requires 3 variables.

\[ \square \]

4 Application to Equational Theories

We now show some consequences of axiomatization properties in a purely equational setting. Remember our convention made before Def. 4, that in this setting, each algebra is considered to be admitted. We restrict \( \mathcal{T}_H \) and \( \mathcal{AX} \) to the set

\[ U := \{ \forall \ldots \forall : t_1 =_S t_2 \mid S \in \mathcal{S}, t_1, t_2 \in T_{V,S}(\Sigma) \} \]

which is trivially a regular tree language.

For a given signature \( \Sigma \) and a class \( A \) of \( \Sigma \)-algebras, let \( \text{vc}(A) \) denote the smallest variety containing \( A \), i.e., the class of all \( \Sigma \)-algebras obtainable from algebras in \( A \) by building subalgebras, Cartesian products, and homomorphic

\(^4\) E.g. \( \exists x \forall y : y = x + y \) follows from \( \forall x : x = x + 0 \) and \( \forall x \forall y : x + y = y + x \).
images. For a set $E$ of equations, let $\text{Mod}(E)$ denote the class of all $\Sigma$–algebras $\mathcal{A}$ with $\mathcal{A} \text{ sat } E$. From Birkhoff’s variety theorem [MT92], it is well known that each class $\mathcal{A}$ of algebras can be characterized by universal equations only up to its variety closure $\text{vc}(\mathcal{A})$. However, it is not clear in general how to find such an axiom set $E$ with $\text{Mod}(E) = \text{vc}(\mathcal{A})$.

If $\mathcal{A}$ is a finite class of finite algebras, we can at least construct an increasing sequence of tree languages characterizing $\text{vc}(\mathcal{A})$ in the limit (Cor. 15). Whenever there exists any finite axiom set $E$ for $\text{vc}(\mathcal{A})$ at all, the sequence of corresponding model classes eventually becomes stationary, and, using Thm. 13, we can obtain a finite axiom set that uniquely characterizes $\text{vc}(\mathcal{A})$. However, convenient criteria for detecting if and when the sequence becomes stationary are still unknown.

**Corollary 15. [Variety Characterization]** For any finite class of finite algebras $\mathcal{A}$, we can compute a sequence $\mathcal{TH}_1 \subseteq \mathcal{TH}_2 \subseteq \ldots$ of sets of universal equations such that $\text{vc}(\mathcal{A}) = \text{Mod}(\bigcup_{i=1}^{\infty} \mathcal{TH}_i)$. If $\text{vc}(\mathcal{A}) = \text{Mod}(E)$ for any finite $E$, we already have $\text{Mod}(\mathcal{TH}_n) = \text{vc}(\mathcal{A})$ for some $n \in \mathbb{N}$. In this case, we can compute a finite axiom set for $\text{vc}(\mathcal{A})$ from $\mathcal{TH}_n$.

**Proof.** Assuming $\mathcal{V} = \{x_1, x_2, \ldots\}$, let $x_i := \langle x_1, \ldots, x_n \rangle$ for $i \in \mathbb{N}$. Let $\mathcal{TH}_i := \mathcal{TH}_{x_i}(\mathcal{A}) \cap \mathcal{U}$ and $\mathcal{TH}_\infty := \bigcup_{i=1}^{\infty} \mathcal{TH}_i$; then, $\mathcal{TH}_i \subseteq \mathcal{TH}_{i+1} \subseteq \mathcal{TH}_\infty$. By Thm. 11, $\mathcal{TH}_\infty$ consists of all universal equations that hold in $\mathcal{A}$.

By Birkhoff’s variety theorem, $\text{vc}(\mathcal{A}) = \text{Mod}(E)$ for some set $E$ of equations. Since $\mathcal{A} \text{ sat } E$, we have $E \subseteq \mathcal{TH}_\infty$, hence $\text{Mod}(\mathcal{TH}_\infty) \subseteq \text{Mod}(E) = \text{vc}(\mathcal{A})$. Vice versa, we have $\text{vc}(\mathcal{A}) \subseteq \text{Mod}(\mathcal{TH}_\infty)$, since $\mathcal{A} \subseteq \text{Mod}(\mathcal{TH}_\infty)$, and $\text{Mod}(\mathcal{TH}_\infty)$ is closed wrt. subalgebras, products, and homomorphic images.

If $E$ is finite, let $n \in \mathbb{N}$ such that all variables in $E$ occur in $x_n$, then $\text{Mod}(\mathcal{TH}_n) = \text{vc}(\mathcal{A})$ as above.

**5 Application to Theorem Proving**

Next, we extend our results to arbitrary formulas of first–order predicate logic. This can easily be achieved by including a sort $\text{Bool}$ and encoding predicates and junctors as functions to $\text{Bool}$. We admit only algebras with an appropriate interpretation of $\text{Bool}$, cf. the convention before Def. 4.

Thus, the equation set $\mathcal{TH}(\mathcal{A})$, and $\mathcal{A}(\mathcal{x})(\mathcal{A})$ corresponds to the set of all formulas in $\mathcal{x}$ valid in $\mathcal{A}$, and a finite axiomatization of it, respectively. Moreover, we can arbitrarily restrict the set of junctors that may occur in a formula. Note, however, that we cannot get rid of any equality predicate, as they are core components of our approach, cf. Def. 6. Hence, we cannot compute the set of all Horn formulas valid in a given algebra.

**Example 16.** As an example of computed predicate–logic axiomatizations, consider $(\mathbb{N} \text{ mod } 2)$ with one function $(\cdot)$ and one predicate $(<)$, where the sort $\text{Bool}$ is interpreted by the two–element Boolean algebra, as required.

---

5 Logical equivalence in $\text{Bool}$
at the same time shows that they do not exist for arbitrary theories. It remains

\[ x + x = 0 \quad 0 < x \wedge 0 < y \wedge 0 < x + y \leftrightarrow false \]
\[ x + 0 = x \quad 0 < x \wedge 0 < y \wedge x < y \leftrightarrow false \]
\[ (y + x) + y = x \quad 0 < x \wedge x < y \leftrightarrow false \]
\[ (x + y) + y = x \quad x < y \wedge y < x \leftrightarrow false \]
\[ (x + y) + y = x \quad 0 < x \wedge 0 < y \wedge 0 < x + y \leftrightarrow x < y \]
\[ y + x = x + y \quad x + y < x \leftrightarrow 0 \wedge 0 < x \wedge 0 < y \]
\[ y < x \wedge (0 < x \wedge y < x) \leftrightarrow y < x \]
\[ y < x \wedge (0 < x \wedge y < x) \leftrightarrow y < x \]

\[ (0 < x \wedge 0 < y) \vee y < x \leftrightarrow 0 < x \]
\[ 0 < y \wedge 0 < x + y \leftrightarrow x < y \]
\[ 0 < y \wedge (0 < x \wedge 0 < y) \leftrightarrow 0 < y \]
\[ x < y \wedge 0 < x + y \leftrightarrow 0 < x \wedge x < y \]
\[ x < y \wedge y < x \leftrightarrow 0 < x \wedge x < y \]
\[ y < x \wedge 0 < x \wedge y < x \leftrightarrow y < x \]
\[ y < x \wedge (0 < x \wedge y < x) \leftrightarrow y < x \]
\[ y < x + y \leftrightarrow y < x \]

\[ y < x \wedge 0 < x \wedge y < x \leftrightarrow 0 < x \wedge x < y \]
\[ y < x \wedge (0 < x \wedge y < x) \leftrightarrow y < x \]
\[ y < x \wedge (0 < x \wedge y < x) \leftrightarrow y < x \]
\[ y < x \wedge (0 < x \wedge y < x) \leftrightarrow y < x \]

Fig. 5. Axiom Set in Exm. 16

Any universally quantified formula in the variables \( x, y \) and with \( \wedge \) and \( \vee \) as the only logical junctors that holds in \( (\mathbb{N} \mod 2) \) follows from the set of formulas given in Fig. 5; formulas with other quantifier prefixes are omitted.

Pure ground formulas and formulas that are instances of others have been manually deleted, as well as formulas that follow from propositional tautologies or symmetry of equality. Equations in \( \mathbb{N} \) are listed first, with index \( \mathbb{N} \) omitted, followed by equations in \( \mathbb{B} \), written as \( \leftrightarrow \). Note that \( (=_{\mathbb{N}}) \) is not contained in the signature of this example but was introduced by our method; consequently, no equality predicate appears in the equations of sort \( \mathbb{B} \), e.g. in a law like \( x < y \vee x = y \vee y < x \leftrightarrow true \).

No formula at all can be reduced to \( true \) by the axioms in Fig. 5, indicating that no valid statements about \( (\mathbb{N} \mod 2) \) can be expressed in \( \Sigma \), except for trivial propositional instances like \( true \vee x < y \). In fact, every expressible formula (i.e. term in \( T_{(x,y),B}(\Sigma) \)) can be falsified by instantiating both \( x \) and \( y \) to 0.

In Cor. 17, we give an application in the field of automated theorem proving. Here, it is common practice to test a conjecture \( \varphi \) in a finite class \( A \) of models of the background theory \( \Theta \) before attempting to prove \( \varphi \) from \( \Theta \). If the test fails, it is clear that \( \Theta \models \varphi \) cannot hold. If the test succeeds, i.e. \( A \) sat \( \varphi \), we are usually still faced with the task of proving \( \Theta \models \varphi \).

We call \( A \) a class of prototype algebras for \( \Theta \), if from a succeeding test we always can conclude the validity of \( \Theta \models \varphi \). In this case, we can decide quickly whether \( \Theta \) entails a formula \( \varphi \), merely by testing whether \( \varphi \) holds in each member of \( A \).

Corollary 17 provides a sufficient criterion for establishing the existence of prototype algebras for an equational – or by the above argument – first–order predicate–logic theory \( \Theta \). Since we cannot deal with arbitrarily many variables, we have to restrict the syntactic class of \( \varphi \) to \( \mathcal{T}_{(\Sigma \cup \{ (=_{\mathbb{B}}) \})} \) for some finite tuple \( z \) of variables.

Example 18 gives a set of prototype algebras for an equational theory, and at the same time shows that they do not exist for arbitrary theories. It remains
to be seen whether it is feasible to extend the prototype approach by adding
certain infinite algebras that allow easy testing\(^6\) of \(\varphi\) to \(A\).

**Corollary 17.** [Prototype algebras] Let \(\Theta\) be a set of formulas, let \(A\) be a finite
class of finite admitted \(\Sigma\)-algebras such that \(A \text{ sat } \Theta\) and \(\Theta \models A \mathcal{X}_\varphi(A)\). Then,
\(A\) is a class of prototype algebras for \(\Theta\) and \(x\). Formally, for any formula \(\varphi\) over
\(\Sigma\) and \(x\) we have \(\Theta \models \varphi\) iff \(A \text{ sat } \varphi\).

**Proof.**

\(\Rightarrow\): trivial: \(A \text{ sat } \varphi\)

\(\Leftarrow\):

\[ A \text{ sat } \varphi \Rightarrow A \mathcal{X}_V(A) \models \varphi \quad \text{by Thm. 13} \]

\[ \Theta \models \varphi \quad \text{since } \Theta \models A \mathcal{X}_V(A) \]

Note that the Corollary holds for arbitrary \(S_{\text{fix}}\) and \(A_{\text{fix}}\), not only for \(\text{Bool}\).
However, we need to fix \(\text{Bool}\) in order to get the notion of \(=\) used in theorem
proving. \(\square\)

**Example 18.** Let \(\Theta\) consist of the axioms for an Abelian group of characteristic 2. Referring to Exm. 14, we can see that \(\Theta\) implies \(A \mathcal{X}_{(x,y)}(A_2)\). Hence, in
order to prove a formula \(\varphi\) over \(\{x,y,0,(+),(=)\}\) to be a consequence of \(\Theta\), it
is sufficient by Cor. 17 just to test it in \(A_2\).

Unfortunately, we cannot get rid of “characteristic” equations: In any finite
algebra with an associative binary operation (+), a law \(n_1x = n_2x\) holds for
some \(n_1 > n_2\), where we abbreviate \(nx := x + \ldots + x\) \((n\ \text{times})\). Hence, each
axiom set obtained from finitely many of such algebras necessarily entails a law
of this form. \(\square\)

**Acknowledgments.** Ingo Dahn drew our attention to the application area of proto-
type algebras in automated theorem proving. Martin Simons provided the literature
reference to the many-sorted version of Birkhoff’s variety theorem. Angela Sodan gave
us some valuable advice on the presentation.
